THE ENCYCLOPÆDIA BRITANNICA

FOURTEENTH EDITION

VOLUME 23

VASE TO ZYGOTE

VASE, a vessel, particularly one of ornamental form or decoration; the term is often confined to such vessels which are uncovered and with two handles, and whose height is greater in proportion to their width. (*See* POTTERIES AND PORCELAINS.)

VASELINE is a term frequently, but inaccurately, applied to the *paraffinum molle* of the British Pharmacopoeia, also known as petrolatum and petroleum jelly, a commercial product of petroleum largely employed in pharmacy, alone and as a vehicle for external application of medicinal agents, especially when local action rather than absorption is desired; as a protective coating for metallic surfaces and for other purposes. "Vaseline" is the registered trade mark of The Chesebrough Manufacturing Co. (Cons'd), used upon a line of products perhaps the best known of which is petroleum jelly.

"Vaseline" petroleum jelly consists of a semi-solid mixture of hydrocarbons, having a melting-point usually ranging from a little below to a few degrees above 100°. It is colourless, or of a pale yellow colour, translucent, fluorescent, and amorphous. It does not oxidize on exposure to the air, and is not readily acted on by chemical reagents. It is soluble in chloroform, benzene, carbon bisulphide and oil of turpentine. It also dissolves in warm ether and in hot alcohol, but separates from the latter in flakes on cooling.

VASILKOV, a town of the Ukrainian S.S.R., in 50° 12′ N., 30° 18′ E., lying south of Kiev. Pop. (1926) 20,743. It is an agricultural centre. Founded in the tenth century, it was laid waste by the Mongols 1239–42, captured by Lithuania in 1320, and later by the Poles. In 1686 it was annexed to Russia.

VASSAL, the tenant and follower of a feudal lord (*see* FEUDALISM). The etymology of the word after much discussion remains obscure. Under the Frankish empire the *vassi dominici,* essentially servants of the royal household, were great officers of State, sent on extraordinary missions into the provinces, to supervise local administration in the interests of the central power. Sometimes they were sent to organize and govern a march, sometimes they were rewarded with benefices, and as, with the growth of feudalism, these developed into hereditary fiefs, the word *vassus* or *vassallus* was naturally retained as implying the relation to the king as overlord, and was extended to the holders of all fiefs whether capital or mediate. In course of time the word came to acquire a military sense, and in mediaeval French poetry *vasselage* is commonly used in the sense of "prowess in arms," or generally of any knightly qualities. In this sense it became acclimatized in England, but in countries which were not feudally organized—in Castile, for instance—vassal meant simply subject, and during the revolutionary period acquired a distinctly offensive significance as being equivalent to slave.

See *Dictionnaire de l'ancienne langue française* (1895), and Du Cange, *Glossarium, s.* "Vassus."

VASSAR COLLEGE, a non-sectarian institution for the higher education of women, two miles east of Poughkeepsie, N.Y., and 75 m. from New York city. In 1861 it was incorporated as Vassar Female college, a name which was changed in 1867 to Vassar college. Immediately after the incorporation, the founder, Matthew Vassar, transferred to a board of trustees of his own selection about $400,000, increased by his will to almost twice that amount, and 200 ac. of land on which the college was to be built. Three buildings were erected and the college was opened on Sept. 20, 1865, but before that time Milo P. Jewett, selected by Mr. Vassar as the first president, had resigned, and John Howard Raymond, one of the trustees, was chosen by the board as his successor. To Dr. Raymond fell the task of creating the curriculum, selecting the entire faculty and planning the organization of the first adequately endowed and equipped college for women. After his death in 1878 Samuel L. Caldwell was called to the presidency. He resigned in 1885 and after one year, during which James Ryland Kendrick served as provisional president, James Monroe Taylor began a long and successful administration (1886–1914).

The number of students increased until in 1906 it was decided to limit them to 1,000; new chairs were established, and many important policies adopted; the preparatory department was abolished and the department of wardens created. In 1915 Henry Noble MacCracken, who is president now (1929), began his administration. While maintaining the early high standards and preserving the spirit and ideals of the founder, he has accepted the changed conditions of the times and adopted modern educational policies. Increasing powers of self-government have been granted to the students. They share with the faculty the responsibility of maintaining the good name of the college, and, through the student curriculum committee, they participate in the discussion of educational problems. Voluntary chapel has been substituted for compulsory attendance at religious services and a Community Church has been established. The curriculum has been revised so

that more freedom is given each student in choosing her course of study and more guidance is given by faculty advisers in making her choice. A new department is that of euthenics, a word that has been defined as the science of efficient living. Its purpose is to apply the arts and sciences to the improvement of living conditions of the individual and the race, and since 1926 there has been held on the college campus a summer institute of euthenics for graduates of Vassar and other colleges, both men and women.

The college opened with a faculty of eight professors and 20 instructors and an enrolment of 353 students. The first graduating class was that of 1867, and comprised four members, to whom were given temporary certificates stating that they were "entitled to be admitted to the *first degree of liberal arts*," the propriety of awarding the degree of *bachelor* to women being questioned at that time; in 1868 these certificates were replaced by diplomas bestowing the degree of A.B. At present (1929) the college has a faculty of instruction numbering 153, 96 of whom are of professorial rank, besides 33 other officers of academic administration. The first lady principal was Hannah W. Lyman (1865–187[1]); in 1913 the office was abolished and in its place was organized the department of wardens, consisting of the warden, who has a house on the campus, and an associate warden in each residence hall. The wardens are responsible for material living conditions and the social life of the college. In 1923 the trustees voted to continue the policy adopted in 1905 of limiting the number of students but to increase the enrolment to 1,150. Candidates are accepted each year according to fitness for college, not to priority of application, the only exception being that candidates who filed their applications before March 1, 1923, are entitled to admission on a non-competitive basis. All applicants must present 15 acceptable entrance units and pass entrance examinations.

The college confers the baccalaureate degree in arts (A.B.) upon the completion of the regular courses of four years, and a second degree in arts (A.M.) upon bachelors of arts of Vassar or any approved college who have completed by examination and thesis a course of advanced non-professional study. In 1928, the endowment was more than $6,500,000 and the funds available for scholarships about $720,000. The present equipment includes about 40 buildings exclusive of faculty houses, and the total area of the college grounds is 1,000 ac.; inclusive of a farm of 600 acres. The library contains over 150,000 volumes. Just west of the campus is the Alumnae house which serves as headquarters for the activities of the alumnae association, including also the offices of the educational secretary and of the *Vassar Quarterly*, and as a centre for returning graduates. The most recent additions are the Georgia Avery Kendrick house which provides apartments and single rooms for about 25 members of the faculty; Cushing hall, named in honour of Florence M. Cushing, a member of the class of 1874 and the first woman elected to the board of trustees; the Mildred R. Wimpfheimer Nursery school which accommodates 35 children and provides facilities for child study; and the Minnie Cumnock Blodgett hall of euthenics with classrooms, laboratories and facilities for research. There is an open air theatre, capable of seating 3,000 people; an old English garden; and an outdoor botanical laboratory designed to contain specimens of all plants growing in Dutchess county.

Student government, especially in social matters, is in effective operation, and all undergraduates are members of the Students' Association empowered by the faculty. (C. RA.)

VASTO (anc. *Histonium*), a fortified town of the Abruzzi, Italy, in the province of Chieti, about a mile from the Adriatic, 32 m. direct S.E. by E. of Chieti and 131 m. by rail from Ancona, 525 ft. above sea-level. Pop. (1921) 11,071 (town); (commune) 14,366. It is surrounded by mediaeval walls, and commands views extending to the Tremiti islands and Monte Gargano.

The ancient *Histonium* was a town of the Frentani, and an Oscan inscription of the period of its independence speaks of censors there, probably officers of the community of the Frentani. It appears to have flourished in Roman times and also lay on the line of the ancient road which prolonged the Via Flaminia to the south-east, and reached the coast here after having passed through Anxanum (Lanciano). It is subject to severe earthquakes.

VATICAN, THE, the official residence of the pope, situated upon the Vatican hill in the city of Rome. The article which follows contains sections on history, art, services, organization, representatives' court, and "Vacancy of the Holy See." *See* also ROME, PAPACY, etc.

HISTORY

The Vatican hill, a low eminence on the right bank of the Tiber at the north-west end of Rome, first began to occupy a place in world history at the death of the Apostle Peter. In Roman times it was a district occupied by villas and gardens. It probably took its name from the *vaticinia* which were pronounced there in the neighbourhood of a famous temple of Apollo. The principal building in the *ager vaticanus* at the time of St. Peter was the circus constructed by Caius Caligula and therefore called *Caianum*. It was here that in A.D 64 and 65 the "great multitude" of Christians mentioned by Tacitus (*Annals* xv., 44), who were accused by Nero of having caused the burning of Rome, were martyred with cruel tortures, which the Roman historian describes in detail.

Tradition.—According to the most wide-spread and authoritative tradition, the martyrdom of St. Peter took place in A.D. 67. The disciples obtained possession of his body, as Roman law allowed them to do, and buried it in a tomb near the Via Cornelia, which ran past the Circus not far from the place of martyrdom. The fact of St. Peter's coming to Rome and his martyrdom there, which is attested by strong historical evidence, is strikingly confirmed by a discovery made in 1912 during the excavations which were made under the Basilica of St. Sebastian on the Appian Way. A number of incised inscriptions (*graffiti*) were discovered on the walls containing invocations to St. Peter and St. Paul in Greek and Latin. This entirely corresponds to the tradition that the bodies of the two Apostles were transported to that spot and remained there some time, possibly for concealment, during the period when the persecutions were at their height. The tradition which places the martyrdom of St. Peter on the Vatican hill is also the oldest and the best established; another view, according to which it took place on the Janiculum near to where the Church of St. Peter-in-Montorio now stands, is now to a large extent discredited amongst scholars. An inscription was placed in 1923 on the site of Caligula's Circus on the small piazza south of the Vatican basilica beside the sacristy. The inscription, which was engraved by order of the *Collegium Cultorum Martyrum*, indicates that the first Roman martyrs suffered death at that spot "under the leadership of the Apostle Peter."

Constantine's Basilica.—The first successors of St. Peter desired to be buried near his tomb; for this reason his third successor, St. Anaclete, was obliged towards the end of the first century A.D. to construct, around the *cella* which contained the body of the Apostle, a *memoria* large enough to contain not only St. Peter's tomb but those of his successors. It was only in the third century that it began to be the custom for the popes to be buried in the catacombs. The Emperor Constantine I. gave freedom to the Church in 313, and showed it all possible marks of favour. He presented the pope with the palace of the senator Plautius Lateranus as a residence. This palace had become imperial property as a result of its confiscation by Nero. Constantine also built the Basilica of the Saviour, now St. John Lateran, which became "the cathedral of the pope" and "the Mother Church and the head of all churches of the city and of the world" (*Urbis et Orbis*). According to tradition it was in 324 that he began the construction of a splendid basilica on the Vatican hill over St. Peter's tomb. This church was enriched with valuable ornaments, including a great golden cross. The tomb

itself remained untouched. Constantine's basilica was not completed until 349, in the reign of Constantius. In order to build it, it was necessary to demolish what remained of Caligula's Circus. Nothing was left of the Circus except the central obelisk, which was moved to the centre of the piazza of St. Peter's in 1586 by order of Sixtus V.

Nothing unfortunately remains of Constantine's basilica or of the splendid monuments with which it was adorned in the course of nearly twelve centuries, with the exception of a few remains preserved in the crypts (*grotte*) of the present basilica. The *Museum Petrianum* was built next the basilica during the pontificate of Benedict XV., and was opened in 1925 under Pius XI. All the monuments relating to the history of St. Peter which existed in various places have been collected in this museum.

Although the history of the present basilica can easily be traced, that of the ancient basilica is extremely difficult to discover. Constantine's basilica had five naves; its walls were adorned with paintings and mosaics, which were much admired by pilgrims; its five doors opened on a great square atrium called Paradisus, which was surrounded by a colonnade and in which there gradually accumulated the tombs of all the popes, emperors, kings and princes who expressed a wish to be buried near St. Peter's tomb.

The most notable of the buildings erected after the Basilica are the Mausoleum, constructed early in the 5th century for the burial of Honorius and Theodosius II., in which other members of the imperial family were also buried, the oratory of St. Andrew, which was dedicated by Pope Symmachus (498–514) and destroyed by Pius VI. in 1776 to make room for the present sacristy, the Campanile built by Stephen II. (752–757), the oratory of Sta. Maria Antiqua whose image is preserved in the crypt of the present basilica, and the oratory of John VII. (705–707), which was built to contain the *Veronica* or Portrait of Our Lord. The remnants of the decorations of this oratory are preserved in the *Museum Petrianum*.

One of the ornaments of Constantine's basilica was the fountain which was placed in the middle of the atrium for the refreshment of pilgrims. It dated from the end of the 4th century, but was repeatedly improved and restored. Nothing remains of it to-day except two bronze peacocks and the central pine-apple, also of gilded bronze, from which the water sprang. This pine-apple is mentioned by Dante in the 31st canto of the "Inferno." The basilica was decorated with mosaics of various periods. Among the most important were that placed on the façade of the oratory of St. Mary-in-Turri under Paul I., that situated near the entrance of the basilica, which represented Our Lord between St. Peter and St. Paul, and which is at present in the crypt, and that representing St. Peter walking on the water, which was executed by Giotto early in the XIVth century by order of Cardinal Stefaneschi. The latter mosaic, which is known as the *Navicella*, was destroyed when the ancient basilica was demolished.

Emperors and Kings.—Of the historical events of which the Vatican Basilica was the scene during the Middle Ages, the most famous, and that which had the most influence on the history of the world, was the constitution of the Holy Roman Empire, which was founded when Leo III., on Christmas Day 800, crowned Charlemagne as emperor of the West with solemn rites. After that time some of the emperors came to Rome to receive their crown from the pope in St. Peter's. The last to do so was Frederick III., who was crowned by Nicholas V. on March 19, 1452. Perhaps the most solemn coronation was that of the Emperor Conrad, who came to Rome accompanied by Canute, king of England, Denmark and Norway, and Rudolph, king of Burgundy, and was anointed by John XIX. on Easter Day 1027. Napoleon I. intended to be crowned in St. Peter's after having been anointed by Pius VII. at Notre Dame in Paris, but his intention was not carried out owing to his dispute with the pope.

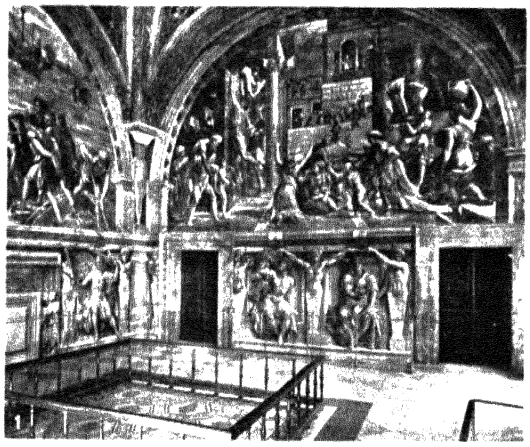
Many kings and princes have made pilgrimages to St. Peter's tomb in the Vatican Basilica. In particular, a number of Anglo-Saxon sovereigns made this pilgrimage, for not far from the Vatican basilica was the *Schola Saxonum* or hospice for English pilgrims. The hospice no longer exists, but it has given its name to the Church of the Holy Spirit in Sassia, which stands near St. Peter's. The first king of the West Saxons to visit Rome was Caedwalla, who was only a catechumen when he arrived at Rome under the pontificate of Sergius I. (689–701). He was baptised in St. Peter's, but died a few days later and was buried in the atrium of the cathedral near the tomb of the Emperor Otho II. King Ina came to Rome in 720 and visited St. Peter's. It was he who founded the hospice for Saxons. Queen Frothogitha came in 787, Ceolwulf, king of Northumberland, in 758, Ethelwulf in 855—he restored and enlarged the Saxon hospice—and Alfred, Ethelwulf's son, was sent as a child by his father to be anointed by Leo IV. and later, in token of his devotion to the Vatican basilica, required each family in his kingdom to pay a silver coin to the pope every year. This was the origin of "Peter's Pence."

The basilica of St. Peter has several times been sacked and devastated. At the time of the barbarian invasions Alaric and Genseric gave orders that it should be respected, but it was not always spared during the civil wars. On some occasions it was occupied by anti-popes, who endeavoured to resist the legitimate pope. The most terrible devastation suffered by the basilica was, however, that of 846, during the Saracen invasion. It was as a result of this event that Pope Leo IV. (847–855) built round the basilica and the Vatican hill a wall called the Leonine Wall after him. The same name has been given to the part of Rome enclosed by the wall. Terrible damage was again done in 1527 by the Lutheran soldiers of Charles V., commanded by the Constable of Bourbon, at the time of the famous sack of Rome.

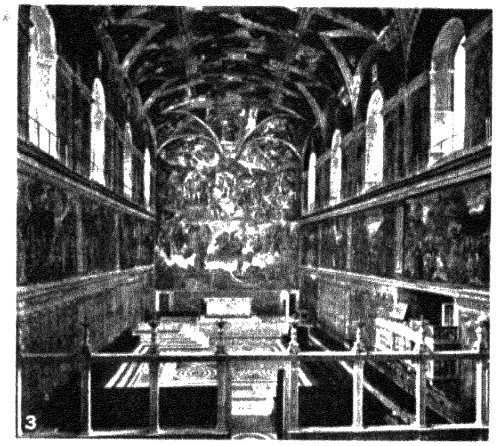
The New Basilica.—When Nicholas V. became pope, Constantine's basilica was falling into ruin. Vain attempts had been made during the preceding centuries to restore the edifice, more particularly by the popes who reigned after the return to Rome following the Western Schism. The basilica leaned so much to one side that the famous architect Leo Baptista Alberti ascertained that the southern wall was 1·75 metres out of the perpendicular. Drastic action was clearly necessary. Nicholas V., on the advice of Alberti, decided that the best, or indeed the only remedy, was to demolish Constantine's basilica, and to build a new one on the same site. The demolition of the apse was begun, but was suspended by the death of this humanist pope.

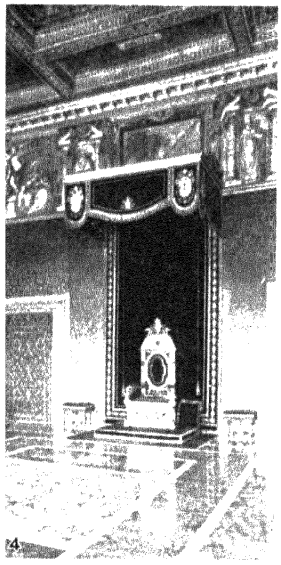
On April 11, 1506, Julius II. laid the first stone of the new basilica, which according to Bramante's original design, was to have been in the form of a Greek cross. Work was carried on with great activity until the end of the pontificate of Leo X. (1521) under the direction of Raphael, who succeeded Bramante in 1514, and that of Giuliano da Sangallo, Fra Giocondo da Verona, Baldassare Peruzzi and Antonio da Sangallo. After the death of Leo X. the work was carried on with less energy until in 1546 Paul III. entrusted its direction to Michelangelo. Michelangelo returned to Bramante's plan, which had been modified by the intervening architects, and added the famous dome, which he himself designed. The work again slackened after the death of Michelangelo (1564), when it was carried on by Vignola, Pirro Ligorio and Giacomo della Porta. Sixtus V., however, took the matter up with his usual energy, and appointed his favourite architect, Domenico Fontana, to act with Giacomo della Porta. In 1590, Michelangelo's great cupola, slightly modified by Giacomo della Porta, was completed after only 22 months' work. In 1603, during the reign of Clement VIII., the new basilica was completed, according to the original plan, in the form of a Greek cross. Some remains of the ancient basilica were still left standing. Paul V. decided in 1605 to demolish them. He adopted Carlo Maderno's plan of giving the basilica the form of a Latin cross by extending the eastern arm. The façade, which was designed by Maderno, was completed in 1612. The new basilica was solemnly consecrated by Urban VIII. on Nov. 18, 1626.

The majestic beauty of the basilica is completed by the splendid piazza which gives access to it. In the centre is an obelisk, and on the two sides are two beautiful fountains constructed by Maderno in the reign of Paul V. The piazza is surrounded by the two marvellous semi-circular colonnades erected by Bernini in 1667 under Alexander VII. They consist of 284 columns of Travertine marble placed in four rows and surmounted

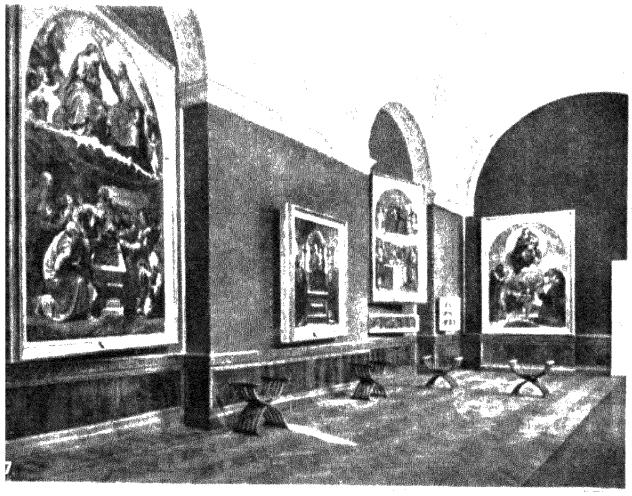


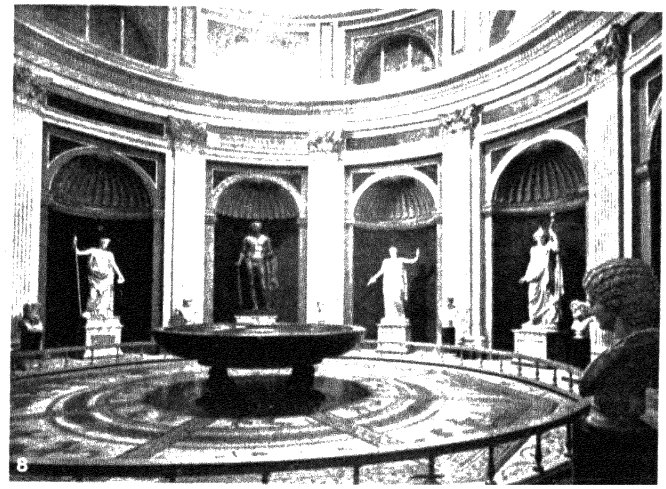
by a balustrade on which are 140 statues. The general effect produced by the piazza is unequalled throughout the world.





The Papal Palaces.—On the left of the basilica (to the spectator's right) is the imposing group of the papal palaces. Symmachus was the first pope to reside in the Vatican, on account of the occupation of the Lateran by the anti-pope Laurentius. He built two episcopal residences, one to the left and the other to the right of the basilica. At the end of the schism, however, he returned to the Lateran. Leo III. improved the left-hand residence for the reception of Charlemagne in 800. Gregory IV. (827–844) built a new residence to be used by the pope when he desired to spend several days near St. Peter's in order to officiate in the cathedral. Eugenius III. (1145–53) began another palace, which was continued by Celestinus III. (1191–98) and completed by Innocent III. (1198–1216). Other buildings were constructed by Innocent IV. (1243–54) and Nicholas III. (1277–80). The latter pope undertook a great deal of building, and may be regarded as the real founder of the Vatican as the residence of the popes. He laid out the Vatican gardens, which were surrounded with walls and towers. When the Holy See was transferred from Rome to Avignon, the Vatican and the Lateran were abandoned and fell into dilapidation. Urban V. resided in the Vatican during his temporary return from Avignon in 1367, and Gregory XI. established himself there when the papacy was finally transferred back to Rome. The Lateran was then abandoned, and the Vatican became the official residence of the popes; from the time of Paul V. to that of Pius IX. they also resided in the Quirinal.





From the 15th to the 17th centuries.—During the Renaissance period the Vatican became a centre of art and culture. The celebrated humanist, Nicholas V. (1447–55), included all the buildings on the left of the basilica in a single palace surrounded with walls and towers, one of the latter of which is still intact. On the ground floor he placed the library, which he enriched with manuscripts collected from all countries. The library was enlarged by Sixtus IV. (1471–84) and was transported to the premises which it now occupies by Sixtus V. in 1588. Nicholas V. commissioned Fra Angelico in 1449 to paint frescoes in a chapel in his apartment. Pius II. (1458–64) and Sixtus IV. (1471–84) enlarged and completed the buildings begun by Nicholas V. Sixtus IV. built the Sistine chapel, which was completed in 1483 and adorned with frescoes by Cosimo Rosselli, Sandro Botticelli, Domenico Ghirlandajo and Pietro Perugino. Half a century later Michelangelo also painted frescoes in the Sistine chapel. Paul II. (1464–71) built colonnades round the court in front of the palace of Nicholas V. and constructed the staircase giving access to the storey on which the library is situated. Innocent VIII. (1484–92) erected a new structure next to the entrance to the papal palace and adjoining the atrium of the basilica. On the side of the Vatican hill which looks towards Monte Mario, he built another palace which was magnificently decorated by Pinturicchio and Mantegna. Little trace now remains of this palace, which was replaced under Pius VI. by new structures intended to be used as museums. Alexander VI. (1492–1503) commissioned Pinturicchio and Mantegna to paint frescoes on the first floor of Nicholas V.'s palace. These frescoes are one of the glories of the Vatican. Julius II. (1503–13) ordered Michelangelo to paint the ceiling of the Sistine chapel, and invited Bramante to come to Rome. This architect, as well as designing the new Vatican basilica as stated above, undertook the systematic arrangement of all the Vatican palaces, reaching from that of Innocent VIII. on the Belvedere to that of Nicholas V. adjoining the basilica. This was the origin of the immense and magnificent rectangular structure which surrounds the court of the Belvedere, and in which in course of time the papal art collections were deposited. This palace was only completed under Pius V. (1559–65). Bramante himself designed the three tiers of galleries or *loggie* which were later extended around the three sides of the court of St. Damasus, formed by the papal palaces. Julius II. also commissioned a number of the most famous artists of the day to decorate the rooms or *stanze* in the Vatican. Raphael was one of the artists so employed at the suggestion of Bramante. Considering him to be superior to all the rest, the pope dismissed the other artists and entrusted Raphael alone with the direction of the work, which was continued under Leo X. (1513–21). Raphael died in 1520, and the decoration of the *stanze* was completed by his pupils under Clement VII. (1523–34). Paul III. (1534–49) recalled Michelangelo and commissioned him to paint the famous "Last Judgment" on the end wall of the Sistine chapel. This painting was completed in 1541. Michelangelo also painted the "Martyrdom of St. Peter" and the "Conversion of St. Paul" in the Pauline chapel which the pope had just had built from the designs of Antonio da Sangallo. The same architect built the *Sala Regia*, which was decorated with frescoes by several painters, including Giorgio Vasari, under Paul III. and Gregory XIII. (1572–85). Next to this hall were two large rooms which were also adorned with frescoes by the order of Paul IV. (1555–59) and Pius V. (1566–72). These rooms were afterwards thrown into one by Bernini and formed the *Sala Ducale*. The decoration of the lower part of the walls was only completed under Benedict XV. (1914–22), who had them covered with coloured marbles. Pius IV. (1559–65) commissioned Pirro Ligorio to build him a summer casino in the Vatican gardens. Pius V. ordered the brothers Antonio and Ignazio Danti to paint maps of the various countries of the world on the walls of the third loggia. These maps throw an interesting light on the history of geographical knowledge. Gregory XIII. ordered the same painters to decorate another large gallery in one of the wings of the Belvedere palace with maps of the various districts of Italy. He constructed the "Tower of the Winds" above the same wing in memory of the reform of the calendar. He extended the three *loggie* which shut in the Court of St. Damasus on the northern side and had them decorated with paintings. He also decorated the *Sale dei Paramenti* which formed a continuation of the *Sala Ducale*.

Sixtus V. had a great palace built from the designs of Domenico Fontana. This is the palace in which the popes reside at the present day. The *loggie*, which look out over the court of St. Damasus, were decorated by Mantovani under Pius IX. (1846–78). Sixtus V. also cut the Belvedere Court in two by building a middle wing connecting the two lateral wings. He transferred the library to this wing, the rooms of which were decorated by Cesare Nebbia, Paride Nogari and other artists. Clement VIII. (1592–1605) completed the great palace which had been begun by Sixtus V., and commissioned Paul Brill and other painters to decorate the Clementine Hall and the Hall of the Consistorium. Paul V. built two other palaces, one adjoining the palace of the Borgia, and the other on the site of the palace of Innocent VIII., which was falling into decay. At this period, however, the popes began to prefer the Quirinal to the Vatican. The Quirinal palace was begun by Gregory XIII., continued by Sixtus V., and completed by Paul V. The popes at first used it for a summer residence on account of its high and healthy situation. They gradually came to occupy it more continuously until 1848, and they only resided in the Vatican from time to time when ceremonies were to be celebrated at St. Peter's or on other specially solemn occasions. Urban VIII. (1628–44) commissioned Bernini to erect the monumental staircase, known as the *Scala Regia*, which gives access to the Vatican palaces. The Scala Regia was recently restored by order of Pius XI.

The 18th and 19th Centuries.—From that period until the end of the 18th century few additions of any importance have been made to the Vatican. As there was not sufficient room for the valuable art collections of the Vatican, Clement XIV. (1769–75) built a new wing parallel to that of Sixtus V. in the Belvedere Court to contain the museum of sculpture. Pius VI. (1775–99) and Pius VII. (1800–23), notwithstanding the difficult conditions which prevailed during their rule as a result of the French Revolution and the reign of Napoleon I., continued and completed the arrangement of the Vatican museums and galleries with a magnificence which may be compared to that of the period of the Medici. Even to-day it is difficult to decide whether to admire most the magnificence of the collections or the beauty of the buildings in which they are housed. The greatest artists of the day—Camporesi, Simonetti, Stern and the immortal Canova—took part in this great work. Later Gregory XVI. (1831–46) founded the

INTERIORS OF THE VATICAN PALACE

1. View of the Stanza dell' Incendio showing the "Incendio del Borgo" painted by Raphael (1483–1520) and his pupils in 1517
2. Loggia of Gregory XIII., one of the many galleries in the palace
3. Interior of the Sistine chapel built for Sixtus IV. by Giovanni di Dolci (d. 1486) in 1473–81. The ceiling frescoes were executed by Michelangelo (1475–1564) in 1508–10
4. The Throne room in the private apartments of His Holiness
5. The Sala Regia, reception room for ambassadors. Frescoes are by Vasari (1512–74), Salviati (1510–63) and Zuccari (1529–66)
6. The Torso del Belvedere in the Museo Pio Clementino, a division of the famous Vatican Museums organized by Clement XIV. and Pius VI. The torso was found in the Campo dei Fiori during the pontificate of Julius II. and bears the signature of the Athenian Appollonius
7. "The Salon of Raphael" in the Vatican Pinacoteca constructed by Pius X in 1909. It contains the Madonna di Foligno, The Coronation of the Virgin and the Theological Virtues and Mysteries, all painted by Raphael
8. Sala Rotunda, a circular room of Greek and Roman sculpture in the Museo Pio Clementino designed by Simonetti (1840–92) after the Pantheon. The table in the centre is of porphyry

Etruscan Museum, and Pius IX. the Egyptian Museum. The latter pope commissioned Podesti to paint frescoes in the Hall of the Immaculate Conception next to Raphael's *stanze*, built the grand staircase, which gives access to the Court of St. Damasus, and the other which leads from that court to the papal apartments. Leo XIII. (1878–1903) entrusted Seitz and Torti with the decoration of the Gallery of the Candelabra. Pius X. moved the collection of paintings to a new gallery looking over the Belvedere Court.

The Vatican Gardens.—Adjoining the group of palaces on the west are the Vatican gardens (*Giardini Vaticani*), in which the popes were accustomed to take their walks following the decision not to leave the Vatican after the entry of the Italian troops into Rome in 1870. The gardens are traversed by part of the old wall of Leo IV., which includes three great towers. The Vatican Astronomical Observatory (*Specola*) is installed in these towers. In 1893 Leo XIII. commissioned Vespignani to build a small summer palace around the principal tower. He did not, however, occupy it for long, as it was found not sufficiently cool and comfortable in hot weather. It was then used as an extension of the *Specola*. The Vatican Observatory plays an important part in the astronomical world. In 1889 it was entrusted with part of the great work of photographing the heavens, which was divided between the principal observatories of the world. Splendid literary and scientific traditions gather round the Vatican gardens. Leo X. held literary assemblies there; Clement VII. in 1533 was present at a lecture given by the Austrian Chancellor, John Vidmenstadt, on the theory of the movement of the earth round the sun. In token of his satisfaction the pope presented the chancellor with a Greek Codex, now to be seen in the Munich Library. Innocent XII. (1691–1700) was present at the experiments made in the Vatican gardens by the famous doctor and physicist Giorgio Baglivi on barometric pressure. Pius XI. in 1923 installed the Papal Academy of Science, known as the "Nuovi Lincei" in Pius IV.'s casino.

There is little to add to the summary of the artistic history of the Vatican which has been given above. The basilica of St. Peter is full of magnificent works of art. In the centre is the colossal bronze baldachino designed by Bernini to the order of Urban VIII. It surmounts the principal altar, below which is the tomb of St. Peter.

The Tomb of St. Peter.—The tomb is the only thing which was scrupulously respected when the old basilica was demolished and the new one built. Julius II. firmly refused to agree to Bramante's scheme that it should be moved in order that the new edifice might have a different orientation from the old. The tomb still remains buried beneath the earth as it had always been throughout the ages, with the golden cross of Constantine and the bronze slabs with which it had been covered by the popes in order to protect it against injury by the weather or by human agency. Even the Saracens who sacked the basilica in 846 were unable to profane the Apostle's tomb, so well was it protected. The last observation of the tomb was made about 1895 by Hartmann Grisar, who was authorized to explore all of the tomb that remains visible. He was able to see through the only opening which still remains unblocked, nearly 1½ metres below the level of the crypt, the ancient marble slab which covered the tomb at a certain distance. The slab is broken in half, but it is still in its place, and a small heap of débris can be seen at the bottom of the sort of little well which is beneath it. Everything corresponds to the state in which, according to the records of the period, the tomb must have been in the middle ages after the incursions of the Saracens and their attempts to violate it. This shows that in spite of all the vicissitudes through which the basilica has passed, St. Peter's tomb has been scrupulously respected and has remained intact.

At the order of Urban VIII. Bernini also constructed at the far end of the apse the magnificent bronze reliquary containing the *cathedra* which, according to tradition, was the seat used by St. Peter at religious ceremonies. The seat is a simple wooden chair which was adorned with carved ivory plaques during the Carolingian period. Bernini placed four colossal bronze statues to support the reliquary. They represent the four great doctors of the Church, St. Augustine and St. Ambrose for the Roman Church, St. Athanasius and St. John Chrysostom for the Greek Church.

There are four colossal statues at the feet of the four great piers which support the dome; the statue of St. Longinus is by Bernini, that of St. Andrew by Duquesnoy, that of St. Helena by Bolzi, and that of St. Veronica by Mochi. There are four balconies or *loggie* placed halfway up the four columns; they were designed by Bernini, who adorned them with the eight columns known as *vitineae* or *torsi*, which were taken from the principal altar of the old Basilica. In niches cut in the other piers of the Basilica are statues of the founders of the religious orders of the Catholic Church. The statues are of different periods, and of various degrees of artistic value.

The pictures over the altars of the basilica are all mosaics, and are reproductions of the masterpieces in the Vatican or in various Roman churches and museums. In the first chapel to the right on entering the basilica is the famous Pietà, sculptured by Michelangelo to the order of Cardinal de la Grolaye.

Tombs of the Popes.—All along the walls of the basilica are placed the tombs of the popes. These are of incalculable artistic and historical importance; they include the tombs of Paul III. by Guglielmo della Porta, Urban VIII. and Alexander VII. by Bernini, Gregory XIII. by Rusconi, Gregory XIV. by Prospero da Brescia, Leo XI. by Algardi, Clement X. by De Rossi; Innocent XI. by Maratta and Bonnot, Alexander VIII. by San Martino, Innocent XII. by Fuga, Benedict XIV. by Bracci, Clement XIII. and Pius VI. by Canova, Pius VII. by Thorwaldsen, Pius VIII. by Tenerani, Gregory XVI. by Amici, Pius X. by Astorri, and Benedict XV. by Canonica. There are also four tombs commemorating members of ruling families; that of Countess Matilde of Canossa by Bernini and his pupils; that of Maria Christhina of Sweden, by Fontana; that of Clementina Sobieski, the wife of James Stuart (the Pretender) by Bracci, and that of the three last Stuarts, James (called the Third), and his two sons Charles (called the Third) and Henry, duke, then the cardinal of York, by Canova. The Crypt contains a number of sarcophagi from the old basilica. One is that of Pope Adrian IV. (Nicholas Breakspeare, the only English pope), on which the Norwegian Government has recently placed an inscription commemorating what he did for Scandinavia. The others include those of Gregory V., Boniface VIII., Nicholas III., Urban V., Nicholas V., Pius II., Paul II., Alexander VI., Pius III., Julius III., Marcel II. and Innocent IX. The Crypt also contains the great porphyry vessel which contained the remains of the Emperor Otho II. Two bronze monuments by the famous sculptor Pollaiuolo also found a place in the new basilica, that of Innocent VIII. and that of Sixtus IV. The latter was recently moved to the *Museum Petrianum*. A marble slab, which was set up in 1928 in the atrium of the sacristy, gives a list of the names of the 142 popes from St. Peter to Benedict XV., who were temporarily or permanently buried in the cathedral. Mention should also be made of the bronze statue of St. Peter which is one of the glories of the basilica. Scholars are not agreed on its period, but there is some ground for assigning it to the pontificate of Symmachus (498–514).

On the pavement of the principal nave of the Vatican Basilica are inscribed in bronze letters the dimensions of the largest Christian churches, all of which are smaller than St. Peter's. Reading downwards from St. Peter's tomb, they are as follows: St. Sophia at Constantinople, Westminster Cathedral, St. Mary-of-the-Angels at Assisi, St. Justina at Padua, Antwerp Cathedral, St. John Lateran, St. Paul-Outside-the-Walls at Rome, Seville Cathedral, St. Petronius at Bologna, Cologne Cathedral, Milan Cathedral, Reims Cathedral, Florence Cathedral, St. Paul's.

It would be impossible to give here even a brief description of the works of art contained in the Vatican. The galleries and museums of the Vatican contain a number of priceless masterpieces in addition to those which were mentioned above in the historical survey. It will be sufficient to mention in the gallery of paintings Raphael's "Transfiguration," and among more recent pictures the splendid portrait of George IV. by Lawrence, sent

by that king as a gift to Pius VII.; in the galleries of sculpture the Hercules in gilt bronze from the Theatre of Pompeii, the Laocoön, the Apollo Belvedere, the Belvedere Torso, which Michelangelo admired, and the Augustus and Doryphore of the "Braccio Nuovo"; in the other galleries, the tapestries designed by Raphael and carried out in the workshops of Van Aelot at Brussels.

RELIGIOUS SERVICES

The religious services carried out in the basilica and in the Vatican palace are of a special character, both by their nature and by the fact that the pope takes part in them.

The basilica of St. Peter does not occupy the first place among Catholic churches from the hierarchical point of view. The first Catholic church is the basilica of St. John Lateran, which is the cathedral of the popes. At the same time, the basilica of St. Peter undoubtedly occupies the first place in the minds of Catholics and in the tradition of Christendom as a whole, both as an object of veneration and as an artistic monument.

The Vatican basilica is served by a chapter of canons and by a large body of clergy, at the head of whom is a cardinal with the title of archpriest. The archpriest has ordinary or episcopal jurisdiction over the clergy attached to the cathedral. The canons of the Vatican basilica are, in virtue of their office, supernumerary apostolic protonotaries, *i.e.*, members of a special category of the highest college of the prelacy. As a general rule, some of them are bishops. Seventeen popes have been elected from among their number: Adrian I. (772–795); Leo III. (795–816); Pascal I. (817–824); Leo IV. (847–855); Benedict III. (855–858); Nicholas I., called the Great (858–867); Stephen VI. (885–891); Innocent III., of the family of the Counts of Segni (1198–1216); Gregory IX., of the family of the Counts of Segni (1227–1241); Nicholas III.-Orsini (1277–1280); Boniface VIII.-Caetani (1294–1303); Paul II.-Barbo (1464–1471); Clement IX.-Albani (1700–1721); Benedict XIV.-Lambertini (1740–1758); Pius VI.-Braschi (1775–1799); Leo XII.-Della Genga (1823–1829); and the present Pope Pius XI.-Ratti, elected in 1922.

In addition to the usual services carried out in the cathedral, certain specially solemn ceremonies, which can only be carried out by the pope, are sometimes held. These are beatifications, canonizations, and Holy Years.

Beatifications and Canonizations.—Since the time of Alexander III. beatifications and canonizations have been carried out exclusively by the pope. The rite of beatification consists in the reading of a papal brief proclaiming the new Blessed, and the first act of "cultus" towards his image and relics. The brief is read in the presence of the cardinal archpriest and the Vatican chapter, the cardinal prefect and the other cardinals who are members of the Congregation of Rites. In the afternoon of the same day the pope goes to the basilica accompanied by his court and the Sacred College of Cardinals, prays before the statue of the new Blessed, and receives the Benediction of the Holy Sacrament. The rite of canonization is of a much more solemn character. The pope himself proclaims the new saint after three "postulations" made by the "Consistorial Advocates" each of which is followed by special prayers asking for the help of the other saints and for light from the Holy Ghost in the solemn act which the pope is about to carry out. After the proclamation of the new saint the pope celebrates the pontifical Mass.

Holy Years.—The Holy Years or Jubilees take place every 25 years. The special rite which then takes place is the passage of the Faithful through a special door called the Holy Door, which exists in the four great basilicas, St. John Lateran, St. Peter's, St. Paul's-Outside-the-Walls and St. Mary's Major. These doors are always walled up except in the Jubilee Year. The Holy Door of the Vatican basilica is opened at the beginning of the Holy Year and closed at the end of it by the pope in person.

On the eve of the Festival of St. Peter in each year, the pope blesses the palliums in St. Peter's. The palliums are white woollen stoles embroidered with small black crosses which archbishops wear around their necks as a symbol of communion with the Holy See. When the palliums have been blessed by the pope, they are preserved in a coffer near St. Peter's tomb, and are only taken out to be sent to new archbishops on their election.

Relics.—The Vatican basilica also contains certain relics which are specially venerated by Catholics. The most famous of these is the Veronica. This is a veil with which, according to a tradition going back to the first centuries A.D. a pious woman named Veronica wiped the Face of Our Lord as He went up to Calvary carrying His Cross. The Saviour's Image is believed to have remained imprinted on the veil. Another equally famous relic is the lance with which the soldier mentioned in the Gospels pierced the Heart of Christ on the Cross. The point of the lance is said to have been preserved by the early Christians and concealed during the period of the conquest of Palestine by the Mohammedans. It was discovered at Antioch at the period of the first crusade, and fell into the hands of the Mohammedans when they reconquered the Holy Land. The Sultan Bajazet II. presented it to Pope Innocent VIII. in 1492. It was brought by a special messenger and was received by the pope with a magnificent ceremony which is described with admiration by the chroniclers of the day. These relics are preserved in one of the four small chapels cut by Bernini in the great piers supporting the dome. They are shown to the congregation in the basilica from the balcony of this chapel at the great festivals of the Church. In the case of the Veronica, in particular, this "ostension" has taken place from the earliest days. Dante refers to the ceremony in the 31st canto of his "Paradiso."

Another ceremony which takes place exclusively in the Vatican basilica is the washing (*lavanda*) of the principal altar with wine and water. This is done on the evening of Holy Thursday after the singing of the *Tenebrae* by the cardinal archpriest and the chapter.

Papal Coronations.—The coronation of new popes also takes place as a rule in the basilica of St. Peter. One of the most characteristic of the coronation rites is the thrice repeated burning of a wisp of tow before the pope by a master of ceremonies who chants: "Holy Father, thus passes away the glory of the world." After the papal Mass, the first cardinal deacon places the tiara with the three crowns (*triregnum*) on the head of the new pope, saying "Receive the tiara with the three crowns, and know that thou art the Father of kings and princes, the Pastor of the universe, and the Vicar on earth of Our Lord Jesus Christ, to whom belongs honour and glory, world without end." The coronation of Leo XIII. (1878) and of Benedict XV. (1914) did not take place in St. Peter's but in the Sistine Chapel.

It should also be remembered that all Catholic bishops are obliged to pay periodical visits *ad limina Apostolorum*, that is to say to the threshold of the Apostles' tomb. In order to do this they go to the basilica of St. Peter and obtain from the canon who is responsible for this duty a certificate attesting that the visit has been made. European bishops have to make this visit every five years, and bishops in other parts of the world every ten years.

Sistine and Pauline Chapels.—In the interior of the Vatican palace, services are held in the Sistine chapel, the Pauline chapel and the pope's private chapels. The Sistine chapel is reserved exclusively for papal ceremonies, that is to say those carried out by the pope in person or in his presence. When the Holy See falls vacant, the funeral service of the deceased pope is held in the Sistine chapel, and the meetings at which the voting for the election of the new pope takes place are also held there.

The Pauline chapel is used exclusively as the place of worship of the inhabitants of the Holy Apostolic palaces, and is for this reason the seat of a special internal parish existing to provide for their spiritual needs. This parish is entrusted to the Augustine Friars, and the parish priest, who bears the title of papal sacristan, is always of episcopal rank. Sometimes the pope himself attends specially solemn ceremonies in the Pauline chapel, but in such cases he is not accompanied by his court.

The pope's private chapels are two in number, one in his official apartments and one in his private apartments. Important persons, sovereigns or diplomats, are sometimes allowed to hear Mass in the chapel in the pope's official apartments and to receive the Sacrament from the pope himself. In the same chapel, on the fourth Sunday in Lent, the pope blesses the "Golden Rose." This

is a spray of roses carved in gold and supported by a vase, also of gold, which the pope presents to a sovereign or a member of a reigning family. In the centre of the principal rose is a small phial in which the pope places a few drops of musk and balsam; he then blesses the rose with a special ceremonial. In former times this ceremony took place once a year, but it is now performed more rarely. Another special ceremony which the pope performs every five years, or more frequently if necessary, is the blessing of the *Agnus Dei*. These are wax medallions made by the Cistercian monks of the Basilica of the Holy Cross in Jerusalem; they are then blessed by the pope with special rites, and are then distributed to the faithful, who hold them in special veneration as pledges of Divine protection.

ORGANIZATION

In addition to its historical and artistic signification, the word "Vatican" has a metaphorical sense in which it stands for the central authority of the Catholic Church, or in other words the pope, with the hierarchical power vested in his person, the administration of the Church, the papal curia, and all the representatives of the Holy See throughout the world.

The hierarchical power of the Catholic Church, though shared in different degrees among those to whom it is entrusted (the lower clergy and bishops), is centralized in the person of the pope as its source. It is true that the Roman Church includes among its dogmas the divine institution of the priesthood in two different degrees (priests and bishops), and recognises the validity of orders conferred even outside its communion provided that the transmission of the priestly office has not been interrupted; but it only admits the transmission as legitimate if it is made by a bishop subject to the supreme authority of the successor of St. Peter, the prince of Apostles and the vicar of Our Lord. Thus the Vatican, as the place which contains St. Peter's tomb and the seat of his successors, the bishops of Rome, sums up and symbolizes, in the minds of Catholics, all that is connected with the dignity, authority and power of their Church.

Cardinals.—The Vatican, being the actual residence of the pope, is also the legal seat of the Sacred College of Cardinals, since they are the advisers most closely attached to the pope's person and form with him a single moral entity. The cardinals were originally the bishops of the districts immediately surrounding Rome, and the priests and deacons of the churches of the city, who formed as it were the council of the bishop of Rome. Little by little, as the administrative machinery was developed and perfected, the highest dignitaries and the most distinguished ecclesiastics of the Catholic Church, not only of Rome and Italy but of all nations, were summoned by the pope (who has the sole right of appointing cardinals) to form part of the Sacred College.

The cardinals meet at the Vatican whenever they are summoned by the pope to hold a collective council or Consistorium. Formerly all ecclesiastical affairs of any importance were discussed in the Consistorium, where each cardinal had to state his opinion on the subject under consideration. As business accumulated, however, this system gave rise to a number of difficulties, and in 1587 Sixtus V., doing what Paul III. had done for the Holy Office and Pius IV. for the application of the rules laid down by the Council of Trent, classified all business into a certain number of categories and entrusted each category to a group or committee of cardinals selected for their special competence.

Congregations.—This was the origin of the Roman Congregations, which are to this day the usual organs for the administration and discipline of the Catholic Church. Their number and organization have frequently varied. In addition to the Congregations set up by Sixtus V., Urban VIII. created the Congregation *de Propaganda Fide*, which deals with missions, and Pius VII. that of "Extraordinary Ecclesiastical Affairs," which is entrusted with questions of diplomatic relations with States. The most important reform in the constitution of the Roman Congregations was that introduced by Pius X. in 1908. They are now definitely regulated by the code of canon law promulgated by Benedict XV. in 1917. Meetings of the cardinals belonging to the different Congregations are always held at the Vatican, except those of the Congregations of the Holy Office and of the Propagation of the Faith, which have their own palaces. The decisions of the Congregations are always subject to the approval of the sovereign pontiff.

In addition to the Congregations which exercise its administrative power and carry out its decisions, the Vatican has three tribunals which exercise its judicial power: the Poenitentiaria, a special court which judges questions of conscience and has no authority except over the conscience of the individual, the *Sacra Romana Rota* and the *Signatura Apostolica*, which possess external authority.

The Rota and the Signatura.—The Rota, which has an extremely brilliant tradition in the legal world, consists of a College of Prelates Auditors who, grouped in threes according to seniority, form a number of judicial commissions which give judgment on all matters coming under ecclesiastical law.

It is because of its organization in a number of groups that this tribunal is known as the Rota. Most of the cases with which it deals are of a matrimonial character, for although the Roman Church maintains without any exception the indissolubility of a marriage contracted and consummated, it does not refuse to consider cases in which it can be shown that there existed at the origin of the marriage a defect or impediment which made it invalid and null. In such cases the Church, though it cannot declare a marriage dissolved, can declare it null. The Rota meets at the Vatican every year for the opening of its discussions. After the Mass of the Holy Spirit has been celebrated in the Pauline chapel, the Rota is received by the pope, who makes a speech inaugurating the juridical year.

The tribunal of the Signatura is composed of cardinals, who consider appeals lodged against decisions of the Rota. It cannot decide on the merits of the question, but may consider whether there has been any error of procedure sufficiently important for the case to be referred back to the Rota, where it will be considered by other judges than those who dealt with it the first time.

The Secretariat of State.—Other bodies forming part of the administrative machinery of the Church are the offices of the Vatican, the chief of which is the secretariat of State. This office is directly controlled by the cardinal secretary of State, whose position in relation to the pope corresponds to that of a prime minister. The secretariat of State is the most definitely political organ of the Vatican. With the assistance of the Congregation of Extraordinary Ecclesiastical Affairs, which is specially connected with it, it deals with all business connected with relations between the Holy See and the various Governments. The cardinal secretary of State and his office are responsible for everything having to do with the *concordats*, with diplomatic relations, with the nomination of bishops, and all matters in which some measure of agreement with the civil authority is necessary, and with the instructions to be given to the Faithful on questions relating to national political life. Every day, before dealing with other business, the pope receives the cardinal secretary of State or one of the prelates responsible for the various branches of the secretariat of State. It is for this reason that the only cardinal who resides in the Vatican is the secretary of State, and the only ecclesiastical administrative office which has its headquarters at the Vatican is the secretariat of State. When in everyday speech reference is made to the attitude or policy of the Vatican, what is meant is generally the activity of the secretariat of State or the papal diplomacy for which the secretariat is directly responsible.

Representatives of the Vatican.—The Vatican exercises its authority not only through its central organs, but also through permanent or temporary representatives.

The permanent representatives of the Vatican or, more correctly, of the Holy See, are divided into two main categories, those of a diplomatic character and those of a purely ecclesiastical character. The first category includes nuncios and inter-nuncios, and the second the Apostolic delegations.

Nuncios.—The distinction between nuncios and inter-nuncios corresponds to that between ambassadors and ministers-plenipotentiary of lay Governments. Nuncios are of two degrees—the first or the second—according to the actual or historical importance of their post. As a general rule they possess the rank of

archbishop. Nuncios of the first class complete their diplomatic careers by their elevation to the rank of cardinal. According to the decisions of the Congress of Vienna (1815) papal nuncios are regarded as the doyens of the diplomatic corps to which they belong, and therefore have precedence over all other members of the diplomatic corps.

Since the World War there has been a great increase in the number of nuncios and inter-nuncios, and reciprocally in the number of ambassadors and ministers accredited to the Vatican. The important part played by the Vatican during the World War will be remembered. It is for this reason that many of the States which were created or enlarged as a result of the War have shown anxiety to maintain continuous relations with the Head of the Catholic Church, and that certain Powers which had broken off relations have decided to renew them.

At the end of 1928 the Vatican had 27 diplomatic representatives: 21 nuncios (Germany, Argentina, Austria, Bavaria, Belgium, Bolivia, Brazil, Chile, Colombia, Spain, France, Hungary, Peru, Poland, Portugal, Prussia, Rumania, Switzerland, Czechoslovakia, Venezuela, Yugoslavia) and 6 inter-nuncios (Central America [including the republics of Costa Rica, Honduras, Nicaragua, Panama and San Salvador], Haiti, Netherlands, Latvia, Lithuania, Luxembourg). Thirty diplomatic representatives are accredited to the Vatican: 9 ambassadors (Germany, Argentina, Belgium, Brazil, Chile, Spain, France, Peru, Poland) and 21 ministers (Austria, Bavaria, Bolivia, Colombia, Costa Rica, Great Britain, Haiti, Hungary, Latvia, Liberia, Lithuania, Monaco, Nicaragua, Portugal, Prussia, Rumania, San Marino, San Salvador, Czechoslovakia, Venezuela, Yugoslavia).

Apostolic Delegates.—The other category of representatives to the Vatican consists of the Apostolic delegates. These prelates have, as a rule, the rank of archbishop, and represent the Holy See, not with the civil authorities, but with the bishops of the country to which they are sent.

At the end of 1928 there were 19 apostolic delegations falling into three categories according to the Roman Congregations to which they are subordinate: the Consistorial Congregation is responsible for the delegations to the Antilles, Canada and Newfoundland, to Estonia, United States of America, Mexico and the Philippines. The Congregation of the Propagation of the Faith is responsible for the delegations to South Africa, Albania, Australia, China, Greece, India, Indo-China and Japan. The Congregation for the Eastern Church is responsible for the delegations to Constantinople, Egypt and Arabia, Mesopotamia, Kurdistan and Armenia, Asia Minor, Persia and Syria.

Other Missions.—The Vatican is sometimes represented in particular parts of the world by prelates who are sent on temporary missions. These are known as Apostolic Visitors. On certain occasions, generally at religious festivals, the Vatican is represented by cardinals sent by the pope with the title of legates *a latere*. Sometimes again cardinal-legates have been sent to discuss religious affairs of the highest importance with sovereigns or heads of States. Thus Cardinal Campeggio was sent as legate to Henry VIII. by Clement VII., Cardinal Pole to Mary Tudor by Julius III. and Cardinal Caprara to Bonaparte by Pius VII. after the signature of the concordat of 1801 to settle various questions connected with the concordat.

THE VATICAN COURT

The papal court, which centres round the person of the pope in the Vatican, is essentially of an ecclesiastical character. At the same time, however, it maintains a magnificence of ceremonial which derives its origin from ancient tradition and from the relations which the papacy has always maintained with the highest secular powers.

The Vatican court is divided into two main categories; the papal chapel and the papal household. The first includes the prelates and dignitaries who take part in the religious ceremonies which the pope attends; the second consists of those who have other duties to perform in the pope's entourage. The papal chapel naturally includes all the cardinals and bishops, while the papal household consists solely of the cardinals called the "cardinals palatine" (the Datary and the secretary of State) and those bishops who belong to the papal antechamber, such as the privy almoner and the papal sacristan. The latter is the parish priest of the Vatican palace. Most of the persons who hold honorary posts in connection with the Vatican belong to both categories.

When the papal court appears as a whole, in procession before the pope, at specially solemn religious ceremonies, either in the Vatican basilica or in the Sistine chapel, it provides a spectacle of dazzling splendour, notable both for its variety and for the splendour of the costumes. It includes the cardinals and bishops wearing their *cappae magnae* trimmed with ermine or their gold-embroidered ecclesiastical vestments, as well as Roman princes with cloaks edged with priceless lace, chamberlains "of cloak and sword" in Spanish 16th century costume, prelates in violet soutanes, knights of Malta in scarlet tunics, officers in armour of steel damascened with gold, and the Swiss Guards in their blue, red and yellow uniform which was designed by Michelangelo. Last in the long procession comes the pope, who is carried on the *sedia gestatoria* which is a sort of throne on a portable platform, carried on the shoulders of 12 servants wearing liveries of crimson damask. One on each side of the throne are two privy chamberlains carrying *flabelli* or immense fans adorned with ostrich feathers. Above the *sedia* is a canopy of cloth of silver, the golden supports of which are borne by eight prelates.

All classes and all ecclesiastical, military and civil orders which have relations with the Vatican are represented in this magnificent procession. A number of specially chosen bishops assist the pope and constitute the College of Bishops Assistant to the Papal Throne. The Superiors and Procurators of the religious orders also have their place in the procession. The heads of the two chief aristocratic Roman families, Prince Colonna and Prince Orsini, take it in turns to assist the pope, and are therefore known as the Princes Assistant to the Papal Throne. Other members of the highest aristocracy of Rome also hold hereditary offices. Prince Chigi is always Marshal of the Holy Roman Church, and Perpetual Guardian of the Conclave. Prince Massimo is always Minister of the Papal Posts (in the old sense of the word posts, which referred to the journeys of the pope when he travelled by post), Prince Ruspoli is always Grand Master of Hospitality (that is to say the person responsible for arranging for hospitality to sovereigns or princes who are the guests of the pope), Marquis Sacchetti is always Grand Quartermaster, or superintendent of the technical services of the Vatican, Marquis Patrizi is always *Vexillifer* or Standard-bearer of the Church, Marquis Serlupi is always Master of the Horse. The protection of the pope's person is entrusted to the papal guard, which consists of cadets of the noble families of the former Papal States, and is always commanded by a Roman prince. The pope's escort is the Swiss Guard, a corps instituted by Julius II. and consisting of Swiss citizens recruited from all cantons of the Swiss Confederation. Originally they were only recruited from the canton of Lucerne. There is always a guard of honour recruited from among the citizens of Rome (*Guardia Palatina d'onore*). A corps of police known as the *Gendarmeria Pontificia* is responsible for maintaining order in the Vatican palace.

The papal court also includes a number of ecclesiastical posts which are always entrusted to members of certain religious orders. The Master of the Sacred Palaces, or Theologian of the Papal Court, is always a Dominican; the Sacristan, or priest of the Apostolic Palaces, is always an Augustine Friar; the Apostolic Preacher who preaches the Advent and Lent sermons in the presence of the pope and his court is always a Capuchin; the Confessor to the Papal Household is always a Servite.

Papal ceremonies are always attended by the diplomatic corps accredited to the Holy See, the Roman patriciate and nobility, and the Knights of Malta and of the Order of the Holy Sepulchre, for whom special tribunes are provided.

HOLY SEE VACANCY

Special interest attaches to the procedure which is followed in the Vatican at times when the Holy See is vacant—*Sede vacante*, in the Latin phrase. During such intervals between two pon-

tificates the Sacred College of Cardinals takes over the work of ecclesiastical administration. Detailed rules are laid down for what is to be done during vacancies; the procedure has repeatedly been modified and improved by successive popes. All previous rules were abrogated by the Constitutions of Leo XIII. (May 24, 1882) and Pius X. (Dec. 25, 1904), which are incorporated in the code of canon law.

The Conclave.—Under these constitutions the seat of the cardinals during the vacancy of the Holy See and the conclave is the Vatican palace. The cardinal camerlengo of the Holy Roman Church, who is the personal representative of the Sacred College in the ordinary administration, takes up his residence there; wherever he goes in the palace he is escorted by the Swiss Guards. Every morning, from the death of the pope to the opening of the conclave, all the cardinals meet in the hall of the Consistorium to hold a congregation, that is to say to consult on current business. Assembled in that hall they receive the condolences of the diplomatic corps and of the Order of the Knights of Malta. The general congregation deals with the most important business, and in addition a special congregation meets daily to transact affairs of minor importance; it consists of the three cardinals who are respectively senior in each of the three hierarchical orders represented in the College of Cardinals (bishops, priests and deacons) as well as of the cardinal camerlengo. At the first general congregation the seals of the deceased pope (the Fisherman's Ring and the leaden seal of the Apostolic Chancellery used for the sealing of Bulls) are handed over to the Sacred College and are at once broken.

On nine consecutive days the obsequies of the pope (called for this reason *novendialia*) are celebrated; on the first six days the services are held in the Vatican basilica and on the last three in the Sistine chapel. At the last service the deceased pope's funeral sermon is preached by a prelate. Up till the last conclave, at which Pius XI. was elected, the cardinals entered into conclave one day after the *novendialia*. In order however to give the cardinals from the most distant parts of the world, such as America and Australia, time to reach Rome, the present pope has increased the interval between the death of the pope and the opening of the conclave to 18 days. On the morning of the day on which they go into conclave, the cardinals meet in the Pauline chapel to hear the Mass of the Holy Spirit celebrated by the doyen of the cardinals, and to listen to a sermon preached by a prelate on the election of the pope.

During the conclave the Vatican palace is closed, and all contact with the outside world is cut off by the walling up of the doors giving access to it. The walls are pierced by rotas or turning-boxes similar to those of enclosed monasteries, through which it is possible to pass objects without seeing the person to whom they are passed, and to converse provided that the voice is raised. The guardianship of the rotas is entrusted to the prelates of the different colleges, and in particular to the clerks of the Apostolic Chamber, who carry out minor administrative functions in the Vatican while the Holy See is vacant. These prelates decide in what cases persons may be authorized to converse with the cardinals through the rotas, are present at such conversations, and inspect all objects which it is desired to introduce into the conclave. The conclave is guarded from the outside by the prince marshal of the Holy Roman Church, an hereditary office vested in the Chigi family, and the prelate at the head of the papal court (the major-domo or master of the chamber). Within the Vatican are only the cardinals with their secretaries or "conclavists," the masters of the ceremonies, certain other ecclesiastics who are entrusted with definite duties, doctors, and the service staff. All matters connected with the conclave are directed by the secretary of the Sacred College and the prefect of papal ceremonies. The admission of each person who resides within the precincts of the conclave must be considered and approved in advance by the general congregation of cardinals. The interior of the Vatican palace is divided into a number of small apartments (*cellae*) corresponding to the number of cardinals; each cardinal is allotted his apartment by lot.

The Election.—Voting takes place in the Sistine chapel, in which a number of small thrones, one for each cardinal, have been placed along the lateral walls for the occasion. Each throne is surmounted by a canopy which is violet in colour in the case of those cardinals created by the deceased pope, and green in the case of those created by previous popes. Immediately after the election has taken place, all the canopies are removed except that over the throne of the cardinal who has been elected pope. In one corner of the chapel there is placed a stove in which the masters of the ceremonies burn the voting papers immediately after each vote. The stove has a small iron pipe which passes out through one of the windows of the chapel. The smoke (*sfumata*) which issues from the pipe enables the crowd assembled on the Piazza of St. Peter to guess how the voting has gone; for when the election is complete, straw is added to the voting papers before they are burned so as to make the smoke thicker and more visible, and thus to intimate that the new pope has been elected.

As soon as the elected cardinal has accepted the pontificate, the first cardinal deacon proceeds to the central balcony in the façade of St. Peter's, and announces to the populace the election of the pope and the name that he has chosen. Soon afterwards the new pope himself, wearing the pontifical robes (for before the first vote took place three sets of robes of different sizes were placed in readiness in a cabinet adjoining the Sistine chapel) appears at the same balcony and gives his first benediction to the crowd assembled on the Piazza. After 1870, on account of the occupation of Rome by the Italian Government, Popes Leo XIII., Pius X. and Benedict XV. gave their benediction from the interior balcony of the Vatican basilica. Pius XI. returned to the older practice, and gave the benediction from the exterior balcony, stating that he did so as a token of peace towards the whole world. On the day that the election has taken place the conclave is opened and the cardinals return to their homes. The coronation of the new pope takes place a few days later in the basilica of St. Peter, the day being fixed by the pope himself. If the new pope does not possess episcopal rank—the last occasion on which this occurred was the election of Gregory XVI. in 1831—the privilege of consecrating him belongs to the Cardinal Bishop of Ostia.

(E. Pu.)

THE LATERAN TREATY

The Lateran treaty between the Holy See and Italy, signed Feb. 11, 1929, like all reconciliations that need careful exploration of the difficulties to be surmounted, demanded powers of negotiation of no mean order. At the outset, the conditions for such negotiations were of a favourable character, as Mussolini (*q.v.*) and his Government were also animated with the desire to end the Roman Question, perhaps being not unmindful of the oft-quoted words of Crispi, who said that the politician who settled the Roman Question would go down in history as Italy's greatest statesman. The treaty was ratified June 7, 1929.

The Negotiators.—While the supreme motive power that brought about the historic reconciliation came from Pope Pius XI. and Mussolini, no account of the great event would be complete without acknowledging the work of the negotiators of the treaty for the Vatican: Cardinal Gasparri, papal secretary of State; Mgr. Joseph Pizzardo, assistant secretary of State; Mgr. Borgongini Duca, secretary of extraordinary affairs; and Prof. Francesco Pacelli, legal adviser of the Vatican.

If only because he came into the full blaze of the limelight on account of being co-signatory with Mussolini of the treaty, Cardinal Gasparri's name is the one which is best known to the general public. But his reputation as a statesman stood very high before this event. Born in 1857 at Capovallanza di Ussita, he was ordained in 1877, and subsequently held the position of professor of canon law at the Propaganda college. In 1894 he was created a domestic prelate, and four years later he attained archiepiscopal rank and became apostolic delegate to Peru and Bolivia. Made a cardinal in 1907, Pope Benedict XV. appointed him secretary of State in Oct. 1914. In 1922 Pius XI. appointed him chamberlain of the Holy Roman Church.

Non-Interference.—Those who fear "Vatican interference" as a result of the renewal of papal sovereignty will be able to set

their fears at rest if they will take the trouble to examine the treaty and the declarations that accompanied its signature. The pertinent clause states: "that the Vatican wishes to remain, and will remain, extraneous to the temporal competitions between other States, as well as international congresses convened for this purpose, unless the parties in conflict appeal unanimously to its mission of peace, and reserves the right in any case to the exercise of its moral and spiritual power." In consequence of this, the Vatican territory will always be considered neutral and inviolable.

On the ratification of the treaty, normal diplomatic relations were established by accrediting an Italian ambassador to the Holy See and an apostolic nuncio to Italy—the dean of the Diplomatic Corps, according to the customary procedure as recognized by the Congress of Vienna in 1815. (*See* PAPACY; PIUS XI.; ITALY.)

VATICAN CITY, the title of the newly-created State of which Pope Pius XI. became sovereign on the ratification of the Lateran treaty, signed Feb. 11, and ratified June 7, 1929. (*See* THE VATICAN; PAPACY; PIUS XI.; ITALY.)

VATICAN COUNCIL, THE, of 1869 and 1870, the last oecumenical council of the Roman Catholic Church, and the most important event in her historical development since the Tridentine synod. The preliminaries were surrounded by the closest secrecy. As early as the end of the year 1864, Pius IX. had commissioned the cardinals resident in Rome to tender him their opinions as to the advisability of a council. The majority pronounced in favour of the scheme, dissentient voices being rare. After March 1865 the convocation of the council was no longer in doubt. Thirty-six carefully selected bishops of diverse nationalities were privately interrogated with regard to the tasks which, in their estimation, should be assigned to the prospective assembly. Some of them proposed, *inter alia,* that the doctrine of papal infallibility should be elevated to the rank of a dogma. In public, however, Pius IX. made no mention of his design till the 26th of June 1867, when Catholic bishops from every country were congregated round him in Rome on the occasion of the great centenary of St. Peter. On the 29th of June 1868 the bull *Aeterni Patris* convened the council to Rome, the date being fixed for the 8th of December 1869. And since the Roman Catholic Church claims that all baptized persons belong to her, special bulls were issued, with invitations to the bishops of the Oriental Churches, to the Protestants and to the other non-Catholics, none of which groups complied with the request.

The object of the Council was long a mystery. The Bull of Convocation was couched in general terms, and specified no definite tasks. The first revelation was given, in February 1869, by an article in the *Civiltà Cattolica,* a periodical conducted under Jesuit auspices. It was there stated, as the view of many Catholics in France, that the council would be of very brief duration, since the majority of its members were in agreement. As a presumptive theme of the deliberations, it mentioned *inter alia* the proclamation of papal infallibility. The whole proceeding was obviously an attempt, from the Jesuit side, to gauge the prevalent opinion with regard to this favourite doctrine of ultramontanism. The repudiation was energetic and unmistakable, especially in Germany. Certain articles on "The Council and the Civiltà," published by Döllinger in the *Allgemeine Zeitung,* worked like a thunderbolt.

In France also a violent conflict broke out. Here it was principally the writings of Bishop Maret of Paris (*Du concile général et de la paix religieuse,* 2 vols., 1869), and of Bishop Dupanloup of Orleans, which gave expression to the prevalent unrest, and led to those literary controversies in which Archbishop Manning of Westminster and Dechamps of Mechlin came forward to champion the opposite cause. In Italy the freethinkers considered the moment opportune for renewing their agitations on a larger scale. That the projected dogma had weighty opponents among the higher clergy of Austria-Hungary, Italy and North America was demonstrated during the progress of the council; but before it met all was quiet in these countries.

Organization.—The Roman see exercised a more pronounced influence on the Vatican Council than upon any previous one. As early as the year 1865 a committee of cardinals had been formed as a "special directive congregation for the affairs of the future general council," a title which was usually abbreviated to that of "Central Commission." Among the earliest preliminaries, a number of distinguished theologians and canonists were retained as *consultors* to the council. The General Congregations, presided over by cardinals, were employed in considering the *schemata* (drafts) submitted to the synod; and provisory votes—not regarded as binding—were there taken. The Sessions witnessed the definitive voting, the results of which were to be immediately promulgated as ecclesiastical law by the pope. The form of this promulgation was, in itself, sufficiently characteristic; for the pope was represented as the real agent, while the acknowledgment of the share of the council was confined to the phrase *sacro approbante concilio.*

On the 8th of December the first session met, and the council was solemnly opened by Pius IX. From beginning to end it was dominated by the "Infallibility" problem.

The first transactions of the council gave proof that numerous bishops held the theory that their convocation implied the duty of serious and united work, and that they were by no means inclined to yield a perfunctory assent to the papal propositions, which—in part at least—stood in urgent need of emendation.

The Opponents of Infallibility.—However, as the Curia could rely upon a complacent majority, it resolved to proclaim a new order of procedure, by means of which it would be possible to end these unwelcome discussions and quicken the pace of the council. By the papal decree of the 20th of February the influence of the committees was increased and the majority was allowed to cut short a debate by accepting a motion for its closure.

The main object, however, of this alteration in procedure was to ensure that if the council could not be induced to accept the doctrine of infallibility by acclamation, it should at least do so by resolution. From the first the general interest was almost exclusively concentrated on this question, which divided the members of the synod into two hostile camps. The presence of striking personalities, whose devotion to the Church was beyond question—Archbishop Scherr of Munich, Melchers of Cologne, Bishop Ketteler of Mainz, Bishop Hefele of Rottenburg, Cardinal Schwarzenberg of Prague, Cardinal Rauscher of Vienna, Archbishop Haynald of Kalossa, Bishop Strossmayer of Sirmium, Archbishop Darboy of Paris, Bishop Dupanloup of Orleans, to say nothing of the others—assured this group an influence which, in spite of itself, the opposing faction was bound to feel.

The Supremacy of the Church.—Among the secret propositions submitted to the council by the Curia was the schema *De Ecclesia Christi,* which was distributed to the members on the 21st of January, and which enunciated the superiority of Church to State in the same drastic terms as in the *Syllabus* of Pius IX. (1864)—a declaration of war against the modern political and social order, which in its day provoked the unanimous condemnation of public opinion. When, in spite of the injunction of secrecy, the schema became known outside Rome, its genuineness was at first impugned; but as soon as the authenticity of the text was established beyond the possibility of doubt, this attempt to dogmatize the principles of the notorious *Syllabus* excited the most general indignation, even in the strongholds of Catholicism —France and Austria.

From the 22nd of February to the 18th of March no meetings of the General Congregations took place, on account of structural alterations in the *aula* itself. During this interval all uncertainty as to whether the question of infallibility would actually be broached was dispelled. On the 6th of March a supplementary article to the schema *De Ecclesia,* dealing with the primacy of the Roman see, was transmitted to the members, and in it the much disputed doctrine received formal expression.

The Triumph of Ultramontanism.—Meanwhile, the elaboration of the all-important business of the council had been quietly proceeding. Influenced by the alarming number of amendments to the schema *De Ecclesia,* and anxious above all to ensure an early acceptance for the dogma of infallibility, the

papal Committee resolved to eliminate everything save the one question of papal authority.

In the general debate, begun on the 13th of May, Bishop Hefele of Rottenburg, author of the well-known *Konziliengeschichte*, criticized the dogma from the standpoint of history, adducing the fact that Pope Honorius I. had been condemned by the sixth oecumenical council as a heretic (680). Others were of opinion that the doctrine implied a radical change in the constitution of the Church: one speaker even characterized it as sacrilege. The contention that the dogma was necessitated by the welfare of the Church, or justified by contemporary conditions, met with repeated and energetic repudiation. The champions of infallibility were, indeed, confronted with no slight task:—to establish their theory by Holy Writ and tradition, and to defend it against the arguments of history. But to them it was no hypothesis waiting to be verified, but an already existing truth, the possession of which no extraneous attacks could for a moment affect. On the 3rd of June the general debate was closed.

In the special debate, which dealt with the proposal in detail, every important declaration with regard to the pope was impugned by one party and upheld by the other; but on the 13th of July it was found possible to conclude the debate. On that day the voting in the 85th General Congregation, on the whole schema, showed that, out of 601 members present, 451 had voted *placet*, 88 *non placet* and 62 *placet iuxta modum*. That the number of prelates who rejected the *placet* would amount to 150 had not been expected.

On the 18th of July, in the fourth public session, the dogma was accepted by 535 dignitaries of the Church, and at once promulgated by the pope; only two members repeated their *non placet*, and these submitted in the same session. The council continued its labours for a few more weeks, but its main achievement was over, and the remainder of its time was occupied with affairs of secondary importance. When, coincident with the outbreak of the Franco-German War, the papal state collapsed, the pope availed himself of the altered situation, and prorogued the council by the bull *Postquam Dei munere* (October 20). The Italian government at once protested against his statement that the liberties of the council would be prejudiced by the incorporation of Rome into the kingdom of Italy.

The Pope and the Church.—The resolutions of the Vatican Council entirely revolutionized the position of the pope within the Church. He is first accredited with "complete and supreme jurisdictionary authority over the whole Church, not simply in matters of faith and morality, but also in matters touching the discipline and governance of the Church; and this authority is a regular and immediate authority, extending over each and every Church and over each and every pastor and believer" (*Sessio* iv. cap. 3, *fin.*; Mirbt, *Quellen*, p. 380).

Again, the dogma implies a fundamental change in the position of oecumenical councils, which, in conjunction with the papacy, had till then been supposed to constitute the representation of the Roman Catholic Church.

The Church and Governments.—In the sphere of politics also the *Vaticanum* was attended by important results. The secular governments could not remain indifferent to the prospect that the proclamation of papal infallibility would invest the *dicta* of the mediaeval popes, as to the relationship between Church and State, with the character of inspired doctrinal decisions, and confer dogmatic authority on the principles enunciated in the *Syllabus* of Pius IX. Nor was the fear of these and similar consequences diminished by the proceedings of the council itself. The result was that on the 30th of July, 1870, Austria annulled the Concordat arranged with the Curia in 1855. In Prussia the so-called *Kulturkampf* broke out immediately afterwards, and in France the synod so accentuated the power of ultramontanism, that, in late years, the republic has taken effectual steps to curb it by revoking the Concordat of 1801 and completely separating the Church from the State.

The general position of Roman Catholicism was consolidated by the Vatican Council in more respects than one; for not only did it promote the centralization of government in Rome, but the process of unification soon made further progress, and the attempts to control the intellectual and spiritual life of the Church have now assumed dimensions which, a few decades ago, would have been regarded as anachronistic.

VATTEL, EMERIC (EMER) DE (1714–67) Swiss jurist, the son of a Protestant minister, was born at Couvet, in the principality of Neuchâtel, on April 25, 1714. He studied at Basel and Geneva. During his early years his favourite pursuit was philosophy; and he published in 1741 a defence of Leibnitz's system against J. P. de Crousaz. In 1746 he obtained from the elector of Saxony, Augustus III., the title of councillor of embassy, accompanied with a pension, and was sent to Bern in the capacity of the elector's minister. Much of his leisure was devoted to literature and jurisprudence. Vattel's reputation chiefly rests on his *Droit des gens, ou Principes de la loi naturelle appliqués à la conduite et aux affaires des nations et des souverains* (Neuchâtel, 1758). He died at Neuchâtel on Dec. 28, 1767.

VAUBAN, SÉBASTIEN LE PRESTRE DE (1633–1707), marshal of France, was born at Saint-Léger-Vauban (Yonne). At the age of ten he was left an orphan in poor circumstances, and his youth was spent amongst the peasantry of his native place. At the age of seventeen Vauban joined the regiment of Condé in the war of the Fronde. He was soon offered a commission which he declined. Condé then employed him in the fortification of Clermont-en-Argonne. Soon afterwards he was taken prisoner by the royal troops, and was converted into a devoted servant of the king. He was employed in the siege of St. Ménéhould and won a lieutenancy, and at Stenay he was twice wounded. He besieged and took his own first fortress, Clermont; in May 1655 he became an *ingénieur du roi*.

After the peace of Aix-la-Chapelle Vauban improved or rebuilt various fortresses. Hitherto the characteristic features of his method of fortification had not been developed, and he followed the systems of preceding engineers. Colbert and Louvois were profoundly interested in the work, and it was at the request of the latter that the engineer drew up in 1669 his *Mémoire pour servir à l'instruction dans la conduite des sièges* (this, with a memorandum on the defence of fortresses by another hand was published at Leiden, 1740). On the renewal of war Vauban conducted the sieges of Rheinbergen and Nijmwegen 1672, Maestricht and Trier 1673, Besançon 1674. He supervised the only defence in which he ever took part, that of Oudenarde, in 1674.

Vauban's introduction of a systematic approach to strong places by parallels dates from the siege of Maestricht, and in principle remains to this day the standard method of attacking a fortress. After the peace of Nijmwegen more fortresses were adapted. Vauban became *commissaire-général des fortifications* on the death of De Clerville, and in 1681 rebuilt the fortress of Strasbourg. At Saarlouis for the first time appeared Vauban's "first system" of fortification. He always retained what was of advantage in the methods of his predecessors. In 1682 his "second system," which introduced modifications designed to prolong the resistance of the fortress, began to appear.

In 1687 Vauban chose Landau as the chief place of arms in Lower Alsace. But side by side with this development grew up the far more important scheme of attack. He instituted a company of miners, and the elaborate experiments carried out under his supervision resulted in the establishment of all the necessary formulae for military mining (*Traité des mines*, Paris, 1740, and 1799; The Hague, 1744); at the siege of Ath in 1697 he employed ricochet fire for the first time to break down the defence. He had indeed already used it with effect at Philipsburg in 1688 and at Namur, but was hindered by the jealousy of the artillery. After the peace of Ryswick Vauban rebuilt or improved other fortresses, and finally New Breisach, fortified on his "third system"— which he called *système de Landau perfectionné*. His last siege was that of Old Breisach in 1703, which he reduced in a fortnight. On Jan. 14, Vauban had been made a marshal of France, a rank too exalted for the technical direction of sieges, and his active career came to an end with his promotion. Soon afterwards appeared his *Traité de l'attaque des places*.

But Louis XIV. was now on the defensive, and the war of the Spanish Succession saw the gradual wane of Vauban's influence, as his fortresses were taken and retaken. The various captures of Landau, his *chef-d'oeuvre*, caused him to be regarded with disfavour; he then turned his attention to the defence; but his work *De la défense des places* (ed. by General Valazé, Paris, 1829) is of far less worth than the *Attaque*, and his ideas on entrenched camps (*Traité des fortifications de campagne*) were coldly received, though they contained the elements of the "detached forts" system now universal in Europe. He now devoted himself to the arrangement of the manuscripts (*Mes oisivetés*) which contained his reflections on war, administration, finance, agriculture and the like. In 1689 he made a representation to the king in favour of the republication of the Edict of Nantes, and in 1698 he wrote his *Projet d'une dix^me^ royale* (see *Economistes financières du XVIIIe siècle*, Paris, 1851), a remarkable work foreshadowing the principles of the French Revolution.

Vauban was impressed with the deplorable condition of the peasantry, whose labour he regarded as the main foundation of all wealth, and protested against unequal taxation and the exemptions of the upper classes. His *dix^me^ royale*, a tax to be impartially applied to all classes, was a tenth of all agricultural produce payable in kind, and a tenth of money chargeable on manufacturers and merchants. This work was published in 1707, and instantly suppressed by order of the king. The marshal died heart-broken at the failure of his efforts a few days after the publication of the order (March 30, 1707). At the Revolution his remains were scattered, but in 1808 his heart was found and deposited by order of Napoleon in the church of the Invalides.

BIBLIOGRAPHY.—Carnot, *Éloge de Vauban* (Paris, 1784) (followed by a critical *Lettre à l'académie*, published at La Rochelle, 1785, and Carnot's reply, *Observations sur la lettre*, etc., Paris, 1785); Goulon, *Mémoires sur l'attaque et défense d'une place* (Paris and Hague, 1740; Amsterdam, 1760; Paris, 1764); works by Abbé du Fay (Paris, 1681) and Chevalier de Cambray (Amsterdam, 1689), from which came various works in English, French, etc. For an account of these works and others which appeared subsequently, *see* Max Jähns, *Gesch. der Kriegswissenschaften*, ii. 1442–47; also Croquez, *La citadelle de Lille, chef-d'oeuvre de Vauban, 1668–70* (1913); Mann, *Der Marschall Vauban und die Volkswirtschaftslehre des Absolutismus* (1914).

VAUCLUSE, a department of France, formed in 1793 out of the countship of Venaissin, the principality of Orange, and a part of Provence, and bounded by Drôme on the north, Basses-Alpes on the east, Bouches-du-Rhône (from which it is separated by the Durance) on the south, and Gard and Ardèche (from which it is separated by the Rhone) on the west. It has also an enclave, the canton of Valréas, in the department of Drôme. Pop. (1926) 230,549. Area, 1,381 sq. miles. In the department east to west chains of the French Alps die down westwards towards the Rhone; the northernmost includes the Montagne de Lure (5,994 ft.) and Mont Ventoux (6,273 ft.) and is separated from the next, the Plateau de Saint Christol (4,075 ft.) by the Nesque river; the river Coulon separates this plateau from the Chaine du Léberon (3,691 ft.), which in turn, is bounded on the south by the Durance. The very numerous streams feed irrigation canals. The climate is that of the Mediterranean region. The valley of the Rhone suffers from the mistral, a cold and violent wind from N.N.W.; but the other valleys are sheltered by the mountains, and produce the oleander, pomegranate, olive, jujube, fig, and other southern trees and shrubs. The winter average temperature is about 41° and the summer average temperature 73°.

Wheat and potatoes are the most important crops; sugar-beet, sorghum, millet, ramie, early vegetables and fruits, notably the melons of Cavaillon, are cultivated, and also the vine, olive, mulberry and tobacco. The truffles of the regions of Apt and Carpentras, and the fragrant herbs of the Ventoux range, are renowned. Sheep are the principal live-stock, and mules are also numerous. Lignite and sulphur are mined; rich deposits of gypsum, fire-clay, ochre, etc., are worked. Beaumes-de-Venise and Montmirail have mineral springs. The industries include the spinning and weaving of silk, wool and hemp, metal-working, printing (Avignon), tanning and the making of paper, bricks, tiles, pottery, glassware and tobacco. The department is served by the P.L.M. railway, and the Rhone is navigable for 40 m. within it. It is divided into 3 arrondissements (Avignon, Carpentras and Cavaillon), 22 cantons and 151 communes. Avignon, the capital, is the seat of an archbishop. The department belongs to the region of the XV. army corps and to the *académie* (educational division) of Aix, and has its appeal court at Nîmes.

The chief towns are Avignon, Apt, Carpentras, Cavaillon, Orange and Vaison (*qq.v.*).

VAUD (Ger. *Waadt*), a canton of south-western Switzerland, lying mainly between the Lake of Neuchâtel and the Lake of Geneva. It is the fourth canton in point of area (*see* VALAIS), and occupies 1,238·6 sq.m., of which 85% is reckoned as "productive" (forests cover 282·6 sq.m., exceeded only by those of Berne and the Grisons). Vaud, with 149·8 sq.m. of water surface of the larger lakes, has over one-quarter of the entire total for Switzerland; this is largely accounted for by its share of Geneva. Parts of Neuchâtel and Morat contribute to the total, but the largest lake entirely in Vaud is de Joux (3·6 sq.m.). There are over 4 sq.m. of glaciers; these and the loftiest summit in the canton (Diablerets, 10,650 ft.) occur in the western Bernese Oberland (S. Vaud). The canton, of very irregular shape, includes nearly all of the northern shore of the Lake of Geneva, and stretches from slightly beyond Bex in the south-east to the Juras on the north-west. A long, narrow eastern tongue extends past Payerne to the Lake of Neuchâtel. Just beyond its tip is the Avenches region, forming an "enclave" in Fribourg. Parts of Fribourg, in turn, form "enclaves" within Vaud along the shore of Neuchâtel. A strip of the right bank drainage of the Rhone (from just above Bex to the Lake of Geneva) lies within the canton, but north and north-east of Lausanne the land is drained by the Broye and Thièle, of the Aar-Rhine basin.

Vaud, with plains near the lakes, is hilly rather than mountainous, and is well supplied with railways, including a part of the main Simplon line through Bex. Lausanne is an important main-lines railway centre, and the canton has numerous small-gauge railways and mountain lines, such as those which connect the north-east shore settlements of the Lake of Geneva with the high lying resorts of Les Avants, Mont Pèlerin and Caux, and those which link up Bex and Aigle with the Diablerets area. In 1920 the population was 317,498, of whom 269,606 were French-speaking, 32,049 German-speaking, and 9,524 Italian-speaking, while 264,522 were Protestants, 46,640 Catholics and 1,803 Jews.

The vineyards (15·4 sq.m.), though showing a considerable decrease during the 20th century, are still the most extensive in Switzerland. White wines predominate; the best come from Yvorne (near Aigle), while the slopes of La Vaux (east of Lausanne) produce both red and white wine. Tobacco is grown in north-east Vaud, particularly near Payerne, and cigars are made at Grandson. Manufactures, on the whole, are unimportant, but Ste. Croix, in the Jura, is world-famed for watches, gramophones, musical boxes and jewellery. The Juras produce limestones and sandstones, and the canton-owned salt-beds at Bex provide raw materials for a thriving chemical industry. Vaud is famed for its health resorts and for its educational establishments; visitors chiefly frequent Lausanne, Vevey, Montreux and Château d'Oex

in the upper Saane valley. Lausanne academy (founded 1537) was raised to university rank in 1890, and several towns are noted for important schools; the modernized (12th century) castle in Yverdon was the residence and school of Pestalozzi from 1806 to 1825. Lausanne (estimated pop. in 1925, 74,250) is the political capital and the fifth town in point of size in Switzerland. The "agglomeration" known as Montreux has 18,250 and Vevey has 12,550. Other important villages or small towns are Yverdon (8,870), Ste. Croix (5,330), Payerne (5,300), Nyon (5,300), Morges (4,675), Saanen (4,550), Aigle (3,840) and Château d'Oex (3,470). Among the interesting historical spots are Avenches (the largest Roman colony in Helvetia), Grandson (scene of the first great victory of the Swiss against Charles the Bold in 1476), and the castle of Chillon (where Bonivard, lay prior of St. Victor, near Geneva, was imprisoned from 1530 to 1536 for defending the freedom of Geneva against the duke of Savoy).

The canton is divided into 19 administrative districts and contains 388 communes. The cantonal constitution dates from 1885. The legislature consists of a *Grand Conseil* of 203 deputies (one member to every 450 electors) with an executive *conseil d'état* of seven members; both bodies hold office for four years. Six thousand citizens can compel the Government to consider any project, whether legislative or constitutional; this *initiative* dates back to 1845. Since 1885 the *referendum* has existed in its "facultative" form (6,000 signatures required) for certain measures, and in its obligatory form for financial matters. The two members of the Federal *Ständerat* are named by the *Grand Conseil,* while the 16 members of the Federal *Nationalrat* are chosen by a popular vote.

History.—The early history of the main part of the territories comprised in the present canton is identical with that of south-west Switzerland generally. The Romans conquered (58 B.C.) the Celtic Helvetii and so thoroughly colonized the land that it has remained a Romance-speaking district. It formed part of the empire of Charlemagne, and of the kingdom of Transjurane Burgundy (888–1032), the memory of "good Queen Bertha," wife of King Rudolph II., being still held in high honour. After the extinction of the house of Zähringen (1218) the counts of Savoy gradually won the larger part of it, especially in the days of Peter II., "le petit Charlemagne" (d. 1268). The bishop of Lausanne (to which place the see had probably been transferred from Aventicum by Marius the Chronicler at the end of the 6th century), however, still maintained the temporal power given to him by the king of Burgundy, and in 1125 had become a prince of the empire. (We must be careful to distinguish between the present canton of Vaud and the old mediaeval Pays de Vaud: the districts forming the present canton very nearly correspond to the Pays Romand.) In 1536, both Savoyard Vaud and the bishopric of Lausanne (including Lausanne and Avenches) were overrun and annexed by Bern. Bern in 1526 sent Guillaume Farel, a preacher from Dauphiné, to carry out the Reformation at Aigle, and after 1536 the new religion was imposed by force of arms and the bishop's residence moved to Fribourg (permanently from 1663). Thus the whole land became Protestant, save the district of Échallens. Vaud was ruled very harshly by bailiffs from Bern. Political feeling was therefore much excited by the outbreak of the French Revolution, and a Vaudois, F. C. de Laharpe, an exile and a patriot, persuaded the Directory in Paris to march on Vaud in virtue of alleged rights conferred by a treaty of 1565. The French troops were received enthusiastically, and the "Lemanic republic" was proclaimed (Jan. 1798), succeeded by the short-lived Rhodanic republic, till in March 1798 the canton of Lèman was formed as a district of the Helvetic republic. This corresponded precisely with the present canton minus Avenches and Payerne, which were given to the canton of Vaud (set up in 1803). The new canton was thus made up of the Bernese conquests of 1475, 1475–76, 1536 and 1555. The constitutions of 1803 and 1814 favoured the towns and wealthy men, so that an agitation went on for a radical change, which was effected in the constitution of 1831. Originally acting as a mediator, Vaud finally joined the anti-Jesuit movement (especially after the Radicals came into power in 1845), opposed the Sonderbund, and accepted the new federal constitution of 1848, of which Druey of Vaud was one of the two drafters. From 1839 to 1846 the canton was distracted by religious struggles, owing to the attempt of the Radicals to turn the Church into a simple department of State, a struggle which ended in the splitting off (1847) of the "free church." In 1882 the Radicals obtained a great majority, and in 1885 the constitution of 1861 was revised. (*See* SWITZERLAND: *History.*)

VAUDEVILLE, a term that in America is applied to an entertainment of songs, dances, dramatic sketches, acrobatic stunts, etc., each of which is announced and presented as a separate successive performance. In England the nearest corresponding term is "variety theatre" (*q.v.*); "vaudeville," rarely used, is practically synonymous to what in America is generally known as "musical comedy" or "revue." This article will deal only with vaudeville as it is known in America.

HISTORY

The American theatrical institution of vaudeville originated in 1883, in Boston, Mass., where a former circus employee, Benjamin Franklin Keith, opened a small museum and show in a vacant candy store next to the old Adams house in Washington street. He called his first "theatre" the Gaiety Museum, and its principal attractions were Baby Alice, a midget weighing 1½ lb., and an ancient (stuffed) "Mermaid." Later among his added attractions were "The Circassian Beauties," a chicken with a human face, and a pair of rising young comedians, Weber and Fields, who performed as a team.

Determined to preserve the general plan of the variety show and at the same time give it refinement and even distinction, young Keith went after the best available stage talent, established strict rules against all forms of vulgarity on the stage, encouraged women and children to patronize his small theatre and began to advertise and describe his show as "vaudeville." He put into operation the idea of continuous performances and soon was able to pay his performers more money than they had been paid in variety and in this manner began to command the best talent available. In 1885 Edward F. Albee joined Mr. Keith and organized the Gaiety Opera Company to present at the lowest popular price the then new and sensational Gilbert and Sullivan light operas.

In 1886 the first link in what has become the longest chain of theatres in the world was added to the parent Boston house, that of the old museum in Providence; following this was the purchase of the old Low's opera house in Providence and the Bijou theatre in Boston. In Philadelphia Mr. Keith built an up-to-date theatre which, with the three other flourishing houses at his command, made possible longer engagements and better salaries to reputable artists. The four theatres were the nucleus from which was developed during the next 40 years the great chain including almost every city of the United States with a population of 100,000 or more. When B. F. Keith died (1911) vaudeville was already the most generally patronized American form of stage entertainment. There were in 1928 approximately 1,000 vaudeville theatres entertaining a daily aggregate of 2,000,000 people with well-chosen acts, feature motion pictures and news reels in every State in the United States and every province of Canada.

Early Vaudeville Artists.—Among the early-day geniuses of variety who became identified with vaudeville were The Four Cohans, of whom George M. Cohan was one, Montgomery and Stone, David Warfield and a number of eminent grand opera stars from Europe. Maurice Barrymore, head of the "Royal Family" of the American stage was one of the early stars of the drama to embark in vaudeville. Ethel and Jack Barrymore made occasional engagements on the big circuits. Mr. and Mrs. Sidney Drew, Sara Bernhardt, Lenore Ulric, Nazimova, William Faversham and hundreds of other great artists of every branch of the theatre have appeared. Dramatists began to write one-act plays and dramatic sketches for vaudeville, and there began a general accession of legitimate actors in short plays.

Growth.—Eastern successes of vaudeville found ready and able followers elsewhere. Kohl and Middleton started vaudeville in Chicago as early as 1886. That same year Gustave Walters opened the Orpheum theatre in San Francisco and launched in the Far West a vaudeville circuit which later merged

with the Keith-Albee organization and which spread and succeeded with almost equal rapidity in the Middle and Far West. F. F. Proctor, manager of the famous Twenty-third Street theatre, New York, changed his policy to continuous vaudeville in 1893; John J. Murdock opened his Masonic Temple Roof as a vaudeville theatre in 1898; Oscar Hammerstein made his Victoria theatre, 42nd street and Broadway, New York, a vaudeville house in 1899; Alex Pantages founded his Northwest Vaudeville circuit in 1900; F. F. Proctor opened his Fifth Avenue theatre (formerly Miner's) in 1900, and Gus Sun started a new Ohio circuit of his own in 1905.

The Keith and Proctor interests joined forces in 1905 to establish the United Booking Office which became the official clearing house and engagement bureau for the employment and booking of vaudeville acts and artists. The great number of minor circuits, independent owners and as yet divergent interests which had now entered the vaudeville field, made it necessary to organize the managers with a view to stabilizing the business, standardizing contracts, regulating conflicting situations and inequalities as between competing theatres and as between the employers and employees of vaudeville. In 1916 the National Vaudeville Artists' Association, Inc., was perfected under the sponsorship of leading members of this branch of the profession. This organization in 1928 listed about 15,000 artists and was regarded as the model combination of fraternal beneficiary industrial organizations.

With the increasing interest in motion pictures during the first three decades of the 20th century, vaudeville houses added picture features, news-reels, comedies, etc., to their programmes. The merger of the two major circuits in 1928—Keith-Albee in the East and the Orpheum in the West—with the simultaneous absorption of some of the foremost motion picture producing companies was one of the greatest developments of the institution of American vaudeville. The miraculous advance of wireless science as applied to motion pictures, radiography and telephonic and phonographic recording brought to public attention the possibilities of television (*q.v.*). Vaudeville was first to envisage the widening possibilities of this new era of entertainment. The Pathé-De Mille motion picture producing organization was absorbed by Keith-Albee; the Film Booking Offices, a motion picture corporation, was next. With that reinforcement major vaudeville added to its resources not only a vast picture producing unit but also the names and services of a number of pre-eminent stars of filmdom. The year 1928 witnessed the further expansion of vaudeville with the unification of the Radio-Keith-Orpheum corporation with the Radio Corporation of America.

Operation.—Vaudeville may be classified as major, minor or independent circuits—the theatres of the latter being operated locally in the same manner that local merchants everywhere may be found operating outside of the great store chain systems of trade. The major circuit and its affiliated minor circuits cooperate through the central metropolitan booking offices; also through the Vaudeville Managers' Protective Association, in which all classifications of the business are represented. This association is also in harmony with the National Vaudeville Artists' Association, with which it co-operates through a joint board of arbitration which rules upon contract forms and all matters of equity as between the employing managers and the artists employed. The cost of acts is fixed by these contracts and varies according to the real, or supposed "drawing value" of the attraction so booked. Celebrity, ability and even notoriety are considered in estimating the draw-power of vaudeville attraction, and the higher the cost the more limited must be the engagement on any circuit. The limitation of the tours of highly expensive acts is due to the fact that the small towns, poorer neighbourhoods and smaller theatres of vaudeville cannot stand the additional "overhead."

The arrangement of the programmes in vaudeville theatres is largely at the discretion of the house manager. The opening act on the stage is usually a silent (technically called "dumb") act, as of acrobats, tumblers or one in which the arrival of the audience will not spoil the effect of the performance. Contrast being deemed of prime importance, similar acts are not listed next to one another. Always there is an effort to build the vaudeville programme towards a climax, so that the most striking and effective numbers come well down upon the programme.

Every modern vaudeville theatre maintains a complete equipment of stage sets which are at the disposal of visiting artists, although most important acts carry their own special scenic, mechanical or decorative necessities, such as athletic apparatus, trick furniture and those properties essential to the full effect and success of their own special act. These they carry with them on tour, and they are handled and placed by the stage crews which every vaudeville theatre employs. Touring vaudeville artists pay their own transportation and maintenance and their salaries are paid by the local manager of the theatre upon the conclusion of their immediate engagement in that house.

(E. F. A.)

VAUGELAS, CLAUDE FAVRE, SEIGNEUR DE, BARON DE PÉROGES (1595–1650), French grammarian and man of letters, was born at Meximieu (Ain), on Jan. 6, 1595. He became gentleman-in-waiting to Gaston d'Orléans, and continued faithful to this prince in his disgrace. Vaugelas was among the original Academicians. In his *Remarques sur la langue française* (1647), he maintained that words and expressions were to be judged by the current usage of the best society, of which, as an habitué of the Hôtel de Rambouillet, Vaugelas was a competent judge. He shares with Malherbe the credit of having purified French diction. His book fixed the current usage, and the classical writers of the 17th century regulated their practice by it. Towards the end of his life Vaugelas became tutor to the sons of Thomas Francis of Savoy, prince of Carignan. He died in Paris in Feb. 1650.

See *Remarques sur la langue française,* edited with a key by V. Conrart, and introductory notes by A. Chassang (Paris, 1880). The principles of Vaugelas's judgments are explained in the *Études critiques* (7e série) of M. Brunetière, who regards the name of Vaugelas as a symbol of all that was done in the first half of the 16th century to perfect and purify the French language. *See* also F. Brunot in the *Histoire de la langue et littérature française* of Petit de Julleville.

VAUGHAN, HENRY (1622–1695), called the "Silurist," British poet and mystic, was born of an ancient Welsh family at Newton St. Briget near Scethrog by Usk, Brecknockshire, on April 17, 1622. From 1632 to 1638 he and his twin brother Thomas (*see* next page) were privately educated by Matthew Herbert, rector of Llangattock. Anthony à Wood says that Henry was entered at Jesus college, Oxford, in 1638, but the statement is uncorroborated. He was sent to London to study law, but turning his attention to medicine, he became a physician, and settled first at Brecon and later at Scethrog to the practice of his art. He was regarded, says Wood, as an "ingenious person, but proud and humorous." It seems likely that he fought on the king's side in the Welsh campaign of 1645, and was present at the battle of Rowton Heath.

In 1646 appeared *Poems, with the Tenth Satyre of Juvenal Englished,* by Henry Vaughan, Gent. The poems in this volume are chiefly addressed to "Amoret," and the last is on Priory Grove, the home of the "matchless Orinda," Mrs. Katharine Philips. A second volume of secular verse, *Olor Iscanus,* which takes its name from the opening verses addressed to the Isca (Usk), was published by a friend, probably Thomas Vaughan, without the author's consent, in 1651. The preface is dated 1647, and the reason for Vaughan's reluctance to print the book is to be sought in the preface to *Silex Scintillans: or Sacred Poems and Pious Ejaculations* (1650). There he says: "The first that with any effectual success attempted a diversion of this foul and overflowing stream (of profane poetry) was the blessed man, Mr. George Herbert, whose holy life and verse gained many pious converts, of whom I am the least." His other works are *The Mount of Olives: or Solitary Devotions,* with a translation, *Man in Glory,* from the Latin of Anselm (1652); *Flores Solitudinis* (1654), consisting of two prose translations from Nierembergius, one from St. Eucherius and a life of Paulinus, bishop of Nola; *Hermetical Physick,* translated from the *Naturae Sanctuarium* of Henricus Nollius; *Thalia Rediviva; The Pass-Times and Diversions of a Country Muse* (1678), which includes some of his

brother's poems. Henry Vaughan died at Scethrog on April 23, 1695, and was buried in the churchyard of Llansantffraed.

As a poet Vaughan comes latest in the so-called "metaphysical" school of the 17th century. He is a disciple of Donne, but follows him mainly as he saw him reflected in George Herbert. He analyses his experiences, amatory and sacred, with excessive ingenuity, striking out, every now and then, through his extreme intensity of feeling and his close observation of nature, lines and phrases of marvellous felicity. By his mystical outlook on Nature he no doubt exercised great influence on Wordsworth, who is known to have possessed a copy of his poems, and it is difficult to avoid seeing in "The Retreat" the germ of the later poet's "Ode on Intimations of Immortality." By this poem, with "The World," mainly because of its magnificent opening stanza, "Beyond the Veil," and "Peace," his fame is assured.

The complete works of Henry Vaughan were edited for the Fuller Worthies Library by Dr. A. B. Grosart in 1871. The *Poems of Henry Vaughan, Silurist,* were edited in 1896 (reprint 1905) by E. K. Chambers, with an introduction by Canon H. C. Beeching, for the Muses' Library; *see* also an edition by L. C. Martin (Oxford, 1914), and by E. Hulton (1904); R. Sencourt, *Outlying Philosophy. A literary study of the religious element . . . in the works . . . of H. Vaughan,* etc. (1925); H. W. Wells, *The Tercentenary of Henry Vaughan* (1922).

VAUGHAN, HERBERT (1832–1903), cardinal and archbishop of Westminster, was born at Gloucester on April 15, 1832, the eldest son of lieutenant-colonel John Francis Vaughan, head of an old Roman Catholic family, the Vaughans of Courtfield, Herefordshire. His mother, a daughter of John Rolls of The Hendre, Monmouthshire, was intensely religious; and all the daughters of the family entered convents, while six of the eight sons took priest's orders, three of them rising to the episcopate, Roger becoming archbishop of Sydney, and John bishop of Sebastopolis. Herbert spent six years at Stonyhurst, and was then sent to study with the Benedictines at Downside, near Bath, and subsequently at the Jesuit school of Brugelette, Belgium, which was afterwards removed to Paris. In 1851 he went to Rome. After two years of study at the Accademia dei nobili ecclesiastici, where he became a friend and disciple of Manning, he took priest's orders at Lucca in 1854. On his return to England he became for a period vice-president of St. Edmund's College, Ware, at that time the chief seminary for candidates for the priesthood in the south of England. Since childhood he had been filled with zeal for foreign missions, and he conceived the determination to found a great English missionary college to fit young priests for the work of evangelizing the heathen. With this object he made a great begging expedition to America in 1863, from which he returned with £11,000. St. Joseph's Foreign Missionary College, Mill Hill Park, London, was opened in 1869. Vaughan also became proprietor of the *Tablet,* and used its columns vigorously for propagandist purposes. In 1872 he was consecrated bishop of Salford, and in 1892 succeeded Manning as archbishop of Westminster, receiving the cardinal's hat in 1893.

It was his most cherished ambition to see before he died an adequate Roman Catholic cathedral in Westminster, and he laboured untiringly to secure subscriptions, with the result that its foundation stone was laid in 1895, and that when he died, on June 19, 1903, the building was so far complete that a Requiem Mass was said there over his body before it was removed to its resting-place at Mill Hill Park.

See the *Life of Cardinal Vaughan,* by J. G. Snead Cox (2 vols., London, 1910).

VAUGHAN, THOMAS (1622–1666), English alchemist and mystic, was the younger twin brother of Henry Vaughan, the "Silurist." He matriculated from Jesus college, Oxford, in 1638, took his B.A. degree in 1642, and became fellow of his college. He remained for some years at Oxford, but also held the living of his native parish of Llansantffraed from 1640 till 1649, when he was ejected, under the Act for the Propagation of the Gospel in Wales, upon charges of drunkenness, immorality and bearing arms for the king. Subsequently he lived at his brother's farm of Newton and in various parts of London, and studied alchemy and kindred subjects. He married in 1651 and lost his wife in 1658. After the Restoration he found a patron in Sir Robert Murray, with whom he fled from London to Oxford during the plague of 1665. He appears to have had some employment of state, but he continued his favourite studies and actually died of the fumes of mercury at the house of Samuel Kem at Albury on Feb. 27, 1666. Vaughan regarded himself as a philosopher of nature, and although he certainly sought the universal solvent, his published writings deal rather with magic and mysticism than with technical alchemy. They also contain much controversy with Henry More the Platonist. Vaughan was called a Rosicrucian, but denied the imputation. He wrote or translated *Anthroposophia Theomagica* (1650); *Anima Magica Abscondita* (1650); *Lumen de Lumine* and *Aphorisimi Magici Eugeniani* (1651); *The Fame and Confession of the Fraternity of R.C.* (1652); and others. Most of these pamphlets appeared under the pseudonym of Eugenius Philalethes.

Vaughan was probably, although it is by no means certain, *not* the famous adept known as Eirenaeus Philalethes, who was alleged to have found the philosopher's stone in America, and to whom the *Introitus Apertus in Occlusum Regis Palatium* (1667) and other writings are ascribed. In 1896 Vaughan was the subject of an amazing mystification in the *Mémoires d'une ex-Palladiste.* These formed part of certain alleged revelations as to the practice of devil-worship by the initiates of freemasonry. The author, whose name was given as Diana Vaughan, claimed to be a descendant of Thomas and to possess family papers which showed amongst other marvels that he had made a pact with Lucifer, and had helped to found freemasonry as a Satanic society. The inventors of the hoax, which took in many eminent Catholic ecclesiastics, were some Paris journalists.

The Magical Writings of Thomas Vaughan were edited by A. E. Waite in 1888. His miscellaneous Latin and English verses are included in vol. ii. of A. B. Grosart's Fuller Worthies Library edition of the *Works* of Henry Vaughan (1871). A manuscript book of his, with alchemical and autobiographical jottings made between 1658 and 1662, forms *Brit. Mus. Sloane MS.* 1741. Biographical data are in E. K. Chambers's Muses' Library edition of the *Poems* of Henry Vaughan (1896), together with an account and criticism of the *Mémoires d'une ex-Palladiste.* These fabrications were also discussed by A. E. Waite, *Devil-Worship in France* (1896), and finally exposed by Gaston Méry, *La Vérité sur Diana Vaughan.*

VAUGHAN, WILLIAM (1577–1641), English author and colonial pioneer, son of Walter Vaughan (d. 1598), was born at Golden Grove, Carmarthenshire, his father's estate, in 1577. He was descended from an ancient prince of Powys. His brother, John Vaughan (1572–1634), became 1st earl of Carbery; and another brother, General Sir Henry or Harry Vaughan (1587–1659), was a well-known royalist leader. William was educated at Jesus college, Oxford, and took the degree of LL.D. at Vienna. In 1616 he bought a grant of land in the south coast of Newfoundland, to which he sent two batches of settlers. In 1622 he visited the settlement, which he called Cambriol, and returned to England in 1625. Vaughan apparently paid another visit to his colony, but his plans for its prosperity were foiled by the severe winters. He died at his house of Torcoed, Carmarthenshire, in Aug. 1641.

His chief work is *The Golden Grove* (1600), a general guide to morals, politics and literature, in which the manners of the time are severely criticized, plays being denounced as folly and wickedness. The section in praise of poetry borrows much from earlier writers on the subject. *The Golden Fleece . . . transported from Cambriol Colchis . . . by Orpheus jun., alias Will Vaughan,* which contains information about Newfoundland, is the most interesting of his other works.

VAUGHAN WILLIAMS, RALPH (1872–), British musical composer, was born at Down Ampney, Glos., Oct. 12, 1872. He studied at Trinity College, Cambridge, where he became Mus. Bac. in 1894, and at the Royal College of Music, with Parry and Stanford. The revival of English folk-song, however, in which he became absorbed, unlocked his latent creative powers. *The Norfolk Rhapsodies* for orchestra (founded on folktunes), and the symphonic impression *In the Fen Country,* on original themes of folk-song character, show his development. Other types of distinctively national music, notably the Tudor Church composers and Purcell, strengthened his technical resources and helped to determine his own style in the direction of vigorous melodic

outline, the free use of model scales, an unflinching contrapuntal texture and a high-handed attitude towards harmony. He wrote the choral works *Toward the Unknown Region* (Leeds Festival, 1907), *A Sea Symphony* (Leeds, 1910), the libretto in both cases being drawn from Walt Whitman, and the orchestra work, *A London Symphony* (Queen's Hall, 1914).

His musical work was interrupted by the World War, in which he served first in the R.A.M.C. and then as a gunner. His greatest works date from the post war period. The most important are: *A Pastoral Symphony for Orchestra* (Royal Philharmonic Society, 1922); *A Mass in G Minor* (Westminster Cathedral, 1923); an oratorio, *Sancta Civitas* (Oxford, 1926). A stage scene from *The Pilgrim's Progress,* called *The Shepherd of the Delectable Mountains;* and the ballad opera, *Hugh the Drover* (words by Harold Child), belong to the earlier period when folklore and folk-songs were the primary inspiration of his work.

VAULT, any covering for an enclosed room, formed of small pieces of material, generally wedge-shaped and arranged with the under sides forming a generally curved surface, in such a way that each separate unit is held in place by its neighbours on either side; a continuous arch; also, loosely, any curved ceiling or covering of a room, irrespective of its material. The word is also used for a room or series of rooms built for storing valuables and enclosed with heavy walls, doors and ceilings specially constructed to withstand the effect of fire or the attacks of burglars, and entered by a burglar-proof door (*see* SAFES; STRONG ROOMS); and, by a somewhat similar extension, to a masonry enclosure in a graveyard, intended either as a permanent tomb or to receive bodies until a final grave is made.

Structural Implications.—Owing to the action of superincumbent weights upon the wedge-shaped pieces that form it, a vault, like an arch (*q.v.*), exerts side thrust, and unless its lower portions are held in place, it will collapse. Even in such nearly homogeneous structures as the Roman concrete vaults, this tendency is present, and if sufficiently weighted, these vaults, like vaults made of wedge-shaped voussoirs (*q.v.*) will fail because of the pushing apart of their lower edges. The result of this is the development either of very thick walls, whose weight and strength are themselves sufficient to withstand the thrust of vaults placed upon them, or else the balancing of thrusts of adjacent walls against each other or the reinforcement of supporting walls by buttresses. Another method of diminishing thrusts is to arrange the vault in such a manner that its haunches, the lower portions on each side, carry a much greater weight than the centre, or crown.

Another peculiarity of the vault, which tremendously affected its design, is the fact that although a vault is rigid when constructed, its component parts, or voussoirs, have to be independently supported in place in some artificial manner, until the final topmost voussoir, or keystone (*q.v.*) is in place. This problem of supporting the vault during construction has led to many experiments in the arrangement of the separate stones or bricks of a masonry vault. Frequently, for instance, the lower portion of a vault will be built with horizontal layers or courses, and only the top courses of wedge-shaped blocks. In Roman concrete vaults a thin layer of brick, light and easy to support, sometimes acted itself as the centring for the support of the concrete upon it. The most interesting development of this structural necessity was the invention of the system of ribbed vaults by the Romans and its epochal development during the late Romanesque and early Gothic periods. Essentially, this system broke up a large vault area into smaller elements separated by independent arches, whose support and construction was a comparatively easy matter. When once built, these arches themselves served to support the centring for the filling in or web of the vault between the arches.

Types.—Vaults are classified according to their shapes and their construction.

Barrel Vault, sometimes called tunnel vault, one whose cross-section is always the same; a continuous arch.

Annular Vault, a similar continuous vault whose supporting walls are concentric circles, like the vault around the apse of some Romanesque churches.

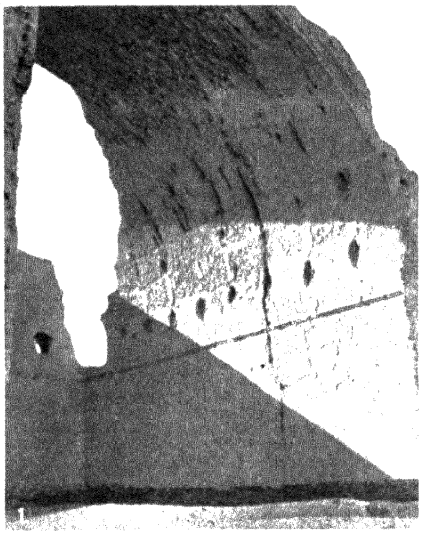
Groined Vault, one formed by the intersection of two vaults running in different directions, usually at right angles to each other, in such a manner that the area covered by the groined vault has arches on its four sides, thus allowing support to be discontinuous and broken up into piers. The lines of the intersection, generally elliptical, are known as groins. In a single, square, groined vault the direction of the thrust follows the line of the groin, and is on a line continuing the diagonals of the square. Where, however, two such square bays adjoin each other, the sum of the two diagonal thrusts is at right angles to the long dimension of the combined two bays. In addition to perfect groined vaults, in which the two elements at right angles to each other are at the same height and curvature, there are many uses of the groined vault over rectangular, instead of square, bays of which the two intersecting vaults are of different curves and heights. The geometrical intersection of such vaults is a warped and twisted line of considerable awkwardness, and various attempts to simplify the form were made either by slanting and warping the surfaces of the component vaults, or by artificially altering the geometric intersecting line to make a more pleasant pattern. The geometric intersection of a small, low vault, with a large, high one, is called a welsh groin.

Dome (*q.v.*), a vault of generally spherical curvature, whose bottom is a circle in plan.

Pendentive (*q.v.*), a small section of spherical vault used to fill in the upper corners of a square or polygonal room to form a circle at the top for the support of a dome.

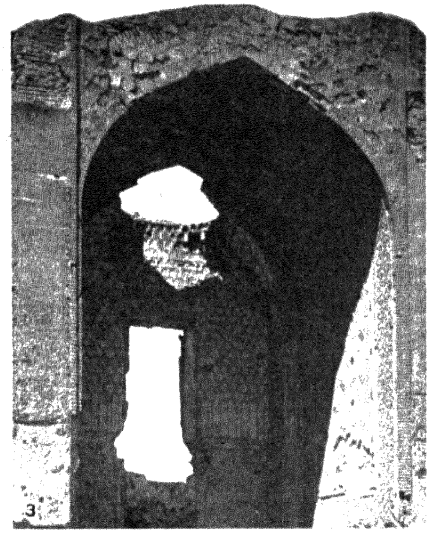
Cloistered Vault, the inverse of a groined vault, also formed by the intersection of two vaults at right angles, but so arranged that from the sides of the square, unbroken sections of vault rise to a point in the centre, so that the intersections, instead of projecting like groins, are like valleys. Many so-called square and octagonal domes are square or octagonal cloistered vaults.

Ribbed Vault, a vault subdivided by independent ribs or arches; also loosely used for any vault with projecting ribs on its surface, whether independent and structurally important or not.

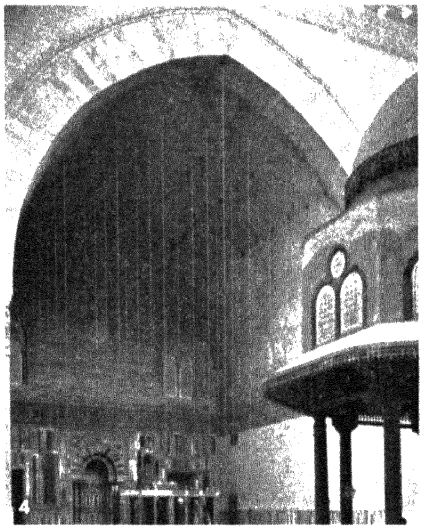


Corbelled Vault, the curved covering of a room, formed not by wedge-shaped pieces of material, in the manner of an arch, but by building the covering of horizontal courses, each one of which projects inward slightly over the one below. This form exerts no thrust and is not strictly a vault, although frequently so called.

HISTORY



Egypt and the Mesopotamian Valley.—The vault seems to have been independently invented in many parts of the world in the late Neolithic and early Bronze ages. The earliest important evidences of it extant are those of Chaldea and early Egypt, where it appears as early as the beginning of the 4th millennium B.C. In Chaldea, not only were drains vaulted, but vaults were also used to cover tomb chambers and probably halls in temples and palaces as well. The vault holds a dominant place in Mesopotamian architecture through all the vicissitudes of Sumerian, Babylonian and Assyrian cultures. During the Assyrian period (*c.* 1000 to 600 B.C.) vaults of unburned brick were the chief method used for covering the long, tunnel-like halls of the Assyrian palaces. The drains which were so important a feature of the palace platforms were roofed with walls of baked brick, and there is preserved an ingenious example from Nimroud (9th century B.C.) showing one method of obviating the necessity for centring. In this case the drain abuts upon a thick wall through which it passes by an arch. The rings of which the vault is formed, instead of being placed in successive vertical planes, are all inclined at 45°, so that each completed ring furnishes a certain amount of support for the one built after it. In addition to the barrel vault, the Assyrians were undoubtedly acquainted with the dome, as many Assyrian reliefs show villages with domed structures, and in some cases the curve of the dome is too flat for it to have been constructed as a corbelled vault.



Egyptian vaults were more common in the earlier periods than in the later and examples in tomb passages at Dendereh undoubtedly go back to the earliest dynasties. Under Rameses II. a granary built behind the Ramesseum at Thebes also had vaulted

MEDIAEVAL AND MODERN VAULTS

1. English decorated Gothic vault of the presbytery of Lincoln cathedral, 1255–80. 2. The nave of S. Ambrogio at Milan, perhaps the earliest complete ribbed, probably dating from the middle of the 11th century. It was the precursor of the Norman vaulting which led eventually to the Gothic vault. 3. The Danish church at Berlin, 1923, has a vault of wooden construction. Like a masonry vault, it exerts thrust. Architect, Otto Bartning. 4. St. Paul's chapel, Columbia University, New York, has a tile vault, of the type known as Guastavino. Architect, John Mead Howells

chambers of which the lower courses were laid horizontal, in order to reduce the span. The Egyptians, however, apparently never appreciated the possibility of cut stone vaulting; the nearest approach to it, in the great period, was the so-called vaulted chambers in the temple built by Seti I. at Abydos.

The Aegean and Greece.—In the pre-classic Aegean, the corbelled vault achieved some of its most remarkable expressions, as in the famous tholoi, or beehive shaped tombs (*e.g.*, tholos of Atreus, at Mycenae, *c.* 1200 B.C.), which are probably modelled on tholos type huts of unburned brick, of which many foundations have been discovered in many sites in Crete and the Grecian islands. Like the Egyptians, the Greeks knew the principle of the arch and the vault, and used it occasionally, although they never gave it an important architectural position, and during the best periods the post and lintel system of construction entirely superseded the vault.

In the Hellenistic period, probably due to the close touch with western Asia that was such a marked feature of post-Alexandrian culture, the arch and the vault again appear, still, however, in isolated instances, in some of which Roman influence may be already present. Thus there is a small hall at Pergamon, Asia Minor, roofed with a groined vault which two schools of thought date differently, one claiming that it is pre-Roman and the other that it is a piece of Roman construction (G. Rivoira, *Roman Architecture,* 1925, p. 78). It is incontestable, however, that barrel vaults, both straight and sloping, were used in Hellenistic tombs and city gates.

Italy.—It is uncertain when and how the Etruscans first discovered vaults, but as early as the 6th century B.C., a tomb from Orvieto, now in Florence, had a simple barrel vault, and by the 4th century they were common, as in the so-called grotto of Pythagoras in Cortona. Moreover, such city gates as those of Falerii, Volterra and Perugia, which date from the 4th and 3rd centuries, B.C., reveal not only a definite knowledge of vault construction but an impressive attempt to give it architectural effect.

It remained for the Romans to absorb the Etruscan knowledge and develop it into the main feature of their architectural construction, and to add to the idea of the cut stone vault, vaults of brick in which the bricks were flat and the radiation taken up in the joints, and vaults of rubble or concrete, roughly dumped upon a wooden centring, whose form it took as it hardened. Vault types were also increased, the cloistered vault appearing in the early 1st century, B.C., as in the Tabularium at Rome (*c.* 80 B.C.); the cross or groined vault, in small square sections supported on arches, so that the whole could be carried by piers, as in the Septa Julia (27 B.C.); independent groined vaults over rooms, common from the time of Nero on (Golden house of Nero, *c.* A.D. 65); and the spherical vault, which appeared first, tentatively, in niche and apse tops, and reached a climactic flowering in the Pantheon of Hadrian.

Under the empire, cut stone vaults were common only in the provinces, like those in Baalbek, Syria or the ribbed vault of the beautiful so-called temple of Diana at Nîmes, France (time of Tiberius). The latter shows one of many interesting experiments made in order to localize thrust and weight; the vault consists of a series of independent stone ribs, on the upper corners of which sinkages are cut to carry stone slabs covering the space between them. A similar experimental genius was at work in the Roman province of Syria, where during the 3rd, 4th and 5th centuries many cut stone buildings were built, in which stone arch ribs supported a roof, either of horizontal stone slabs, as in the so-called basilica at Shakka, or following the curves of the arches, as in the delicately designed praetorium at Musmiyeh. In Rome, vaults were usually of brick or concrete, even when the sub-structure was cut stone, and in the great number of cases, in a combination of the two materials. Brick ribs were frequently used in important positions, and were occasionally double, with the two lines connected by occasional large tiles, forming a light but exceedingly rigid structure. In some cases the whole vault centring was covered with tiles laid flat-wise, which acted themselves as centring for the concrete, and were keyed to it by occasional tiles set end-wise. From the time of the Antonines on, vaults were extremely light, and at times daringly thin, strengthened, not only by ribs of brick, but by arches of brick, built in the plane of the vaults between the ribs. This Roman structural ingenuity grew continuously till the end of the 4th century, long after decorative art had begun to decay.

With these ingenious vaults the Romans produced their characteristically large and impressive interiors, and by the use of cross vaults, as in the great halls of the thermae (*see* BATHS), were enabled to flood them with light from clerestorey windows. Not only were all types of barrel and groined vaults used, as well as the simple dome, but constant experiments were made, almost up to the time of the fall of Rome, in new combinations and novel forms. Many attempts were made to place a dome over a polygonal or square room, thus approaching the pendentive (*q.v.*), and all sorts of scalloped and varied dome types are found. like the scalloped dome of the vestibule of the Piazza D'Oro and the niche of the Serapeum, both in the villa of Hadrian, and the daringly delicate so-called temple of Minerva Medica, at Rome, a garden building of the time of Valerian.

The earlier vaults were covered with stucco and delicately panelled in relief, occasionally further decorated with colour, as in the tepidarium of the baths of the forum at Pompeii (*c.* 80 B.C.), and various rooms in the Golden house of Nero, as well as the remarkably rich subterranean basilica outside the Porta Maggiori at Rome, which probably dates from the time of Augustus. In the later empire, the custom of coffering, or decorating with deeply sunk geometric panels, like those cut into the dome of the Pantheon at the time of Septimius Severus, became common.

The scale of many of these Roman vaults is, even to-day, astounding. Thus the throne room of the palace of Domitian had a barrel vault 97 ft. in span, 8 ft. wider than the nave of S. Peter's; the basilica of Constantine, a groined vault 84 ft. in span; and the domes of the calidarium, in the baths of Caracalla and of the Pantheon, are respectively 116 and 140 ft. in diameter. For a thorough discussion of Roman vaulting *see* G. Rivoira, *Roman Architecture,* noted above.

Byzantine.—The great contribution of the Byzantine builders to vaulting was the final logical development of the pendentive (*q.v.*) through the recognition of the fact that all of the Roman attempts to put a dome on a square plan by means of corbelling were awkward followings of a wrong method, and the discovery of the simplest and most efficient method by substituting triangular sections of a spherical vault. In this way, a dome could be supported on pendentives, which could, in turn, be supported on four great arches, so that the entire weight was brought down upon piers at the corners—a method that at once gave enormous freedom to the planning of a building. The only requirement was that sufficient buttresses should be furnished to withstand the thrust of the great arches. There is much discussion as to where and how the pendentive was finally developed; it is very probably an eastern invention, and may have originated in the cut stone work of Roman Syria. Fully developed pendentives occur during the 5th century, *e.g.*, the church of S. Sophia at Salonica, but it was in the church of S. Sophia at Constantinople (begun 532) that the possibilities of this type of construction were first taken advantage of. The use of great half domes, with smaller domed niches opening from them, at each end of the building. gained a sense of direction—a long axis—while preserving the dominance of the central dome. The two first domes built on this church both collapsed soon after construction, and it is probably only with the building of the present dome that the circle of 40 windows around the base was introduced, which not only lightens the weight of the dome but also furnishes a beautiful illumination for the interior. These windows are not placed in a drum, as in later Byzantine work, but pierced through the curving surface of the dome itself, with buttresses between them on the exterior, whose upper sides are swept up in a curve to meet the curve of the dome. Little hood arches are thrown across between the buttresses, over the windows, and on the exterior give something of the effect of a drum. There is a similar lack of drum in S. Mark's at Venice (2nd half of the 11th century);

and in many Byzantine churches, even where a marked drum exists on the exterior, there will be little or no drum inside.

Besides using pendentives to support a dome, the Byzantine designers discovered that a continuous, spherical vault, ending in arches at the walls, could be used over any square or rectangular space. This is known as the pendentive dome. An early example is in the tomb of Galla Placidia, at Ravenna (*c.* 440). This type is used in combination with all sorts of groined and intersecting vaults in various subsidiary positions. The variety and ingenuity of the side aisle vaults of S. Sophia at Constantinople is remarkable, and is matched by the similar variety in the side aisle vaults of such Italian Byzantine churches as that of S. Vitale, at Ravenna (547) and S. Lorenzo, at Milan (*c.* 560).

In the effort to lighten vaults the Byzantine builders carried to its logical conclusion a method used experimentally by the Romans—that of incorporating in the masonry of a vault, hollow jars or tubes. The dome of S. Vitale, at Ravenna, is built almost entirely of a continuous double spiral of such tubes, shaped so that one fitted into the neck of the next. For a similar reason, the dome of S. Sophia at Constantinople was built of a special type of exceedingly porous and spongy brick.

Mohammedan.—The Mohammedan builders borrowed extensively from Byzantine precedent. In Persia, there is an additional legacy from the enormous vaults built by the Sassanians. Not only did such colossal vaults as those at Firuzabad (459–485) and Ctesiphon (*c.* 550, 82 ft. span) vitally inspire the great vaulted entrances of Persian mosques, but also the wide-spread use of niche-shaped squinches, instead of pendentives under a dome, is without doubt due to the same source. But the Mohammedans developed many characteristic vaulting forms of their own. Especially noteworthy is the multiplication of niche squinches until the stalactite form is achieved, and in the Moorish and Indian styles, the ingenious use of cross ribs, in a square or polygon, to enable it to be covered with a dome of smaller size. Examples in Spain are the vaults over the Maksoûra, or enclosed prayer space, of the great Mosque at Cordova (11th century), and the even richer vault of the chapel Villa Viciosa, in the same mosque. In India the most remarkable example is that of the vast tomb of Mohammed Sikri at Bijapur (1626–60), in which, by arranging arched ribs in two intersecting squares, to form an eight-pointed star, in plan, a hall 135 ft. square is reduced to a central opening 97 ft. in diameter, above which is a dome 124 ft. across, so that there is a gallery around the inside of the dome at its spring. A similar scheme is used in the great mosque of the same town (*c.* 1560), in which a square 70 ft. across is reduced to a circle 57 ft. in diameter.

China.—The Chinese knew the principle of the arch and vault at an early date, probably having developed it independently. Thus vaults occur in the two "Wild Goose" pagodas at Sianfu in the province of Shensi, which are as early as the beginning of the 8th century. The most monumental extant uses of the vault, are however, chiefly of the Ming dynasty and later, and in the four northern provinces of Chili, Shantung, Shensi and Shansi. Groined vaults are not used, but barrel vaults are common in city gates (Peking, Sianfu and Taiuanfu), temple and palace entrance halls (imperial palace at Peking, Temple of Heaven, Peking, etc.) and in many beautifully designed and carefully executed cut-stone bridges. Barrel vaults are occasionally used over temple halls, set at right angles to the axis of the temple, and entered by smaller barrelled vaults and arched gateways in the thickness of the wall. The most remarkable examples of this use occur in the masonry built temple groups of Kin Tze and Shuang la Sze at Taiuanfu, both in Shansi and both dating from the later years of the Ming dynasty. Later examples are the many barrel vaults in the great monastery, temple and palace group, built in the 18th century at Jehol.

Romanesque.—Romanesque vaulting represents the slow development of untrained builders in vaulting a church structure, generally of basilican plan. In this development they made use of Roman precedent, they copied Byzantine technique and they used their own native ingenuity. The groined vault appeared early in aisles and the annular vault, around apses and for circular structures; the dome and the octagonal cloistered vault were used for the crossing. The difficulty was with naves, for the buttressing of a nave vault, high in the air, was a troublesome necessity. Barrel vaults were first tried, either semi-circular or pointed, the pointed section being used because it exerted less thrust, and buttressing was largely achieved by means of the triforium gallery vaults, over the side aisles, which were either semi-circular or quadrant shaped, as in the church of S. Sernin, at Toulouse (late 11th century). Vaulting was usually of stone, and varied from extremely rough workmanship, covered with plaster, as in S. Nectaire, in Auvergne, France (beginning of the 12th century), to the beautiful cut stone of such domed churches as that at Cahors, France (1119). The barrel vaulted nave had the drawback of being dark, as only the smallest clerestorey windows —if any—were possible, and the centring required for it was unduly heavy. The first improvement was the introduction of cross ribs, as in Valence cathedral (early 12th century), which strengthened the vault over the piers and simplified the question of centring. The matter of lighting was more difficult; an early, interesting experimental solution is that of S. Philibert, at Tournus, France, where heavy arches were thrown across the nave at each pier, and walls carried up upon them. Upon these, little barrel vaults were built, running across the nave. The result permitted large clerestorey windows and was statically correct, but the interior effect was unpleasantly discontinuous. Another remarkable solution was reached in the domed churches of Aquitania, where Byzantine influence was strong, but the most beautiful of these, such as Cahors and Angoulême (1132) have no side aisles, and the difficulty of domed churches with side aisles was just as great as in those with barrel vaults; this may be readily seen in the impressive and gloomy interior of Le Puy en Velay (12th century).

The groined vault, which was the obvious answer to the difficulty, was hard to construct because the different widths of nave and aisles, meant that square vaults over the one necessitated oblong vaults over the other. And the intersections of the oblong vaults were twisted and ugly. Furthermore, the aisle vaults around an apse presented difficulties in that the cross vaults were cone-shaped and intersected the annular surface of the aisle vault in unpleasant, twisted lines, with the point where the groins crossed below the high point. No matter how the surfaces were warped, the problem of the intersection remained.

The answer to the problem of nave vaulting was first found by the Lombards in S. Ambrogio, at Milan (begun in the 10th, but probably vaulted about the middle of the 11th century). In this vault, two bays of the aisles are made to equal one of the nave, so that all the vaulting bays are approximately square. Moreover, the system of ribs, which had only appeared tentatively before, was here applied completely; not only were cross ribs built at each alternate pier across the nave, but in addition, arched ribs were built on the groin lines. In this way, a framework of arches was created, easy to construct, and the filling in of the surfaces between, or webs, could be done in sections. The cross vaults allowed clerestorey lighting.

The Normans made the next great advance, through the introduction of an additional rib across the nave, on the piers between those that carried the cross arches, and the treatment of each of the two halves of the nave vaulting bay, with its own wall arch and window; the cross vaults thus established, ran obliquely to the centre. The result is the sexpartite or six-part vault (*q.v.*). Along with this came the solution of the buttressing problem by means of rudimentary flying buttresses. Variations of the six-part vault appear in the two great abbey churches at Caen (Abbaye aux Hommes, Abbaye aux Dames, founded by William the Conqueror and his wife and vaulted in the 12th century). In the Abbaye aux Dames, the idea is tentative only, and the intermediate rib carries a simple wall up to the ridge of the single cross vault. Durham cathedral (1128–1133) has a complete system of groined, ribbed vaults, in which the vaults are four-part instead of six-part, although alternate cross ribs are omitted.

French Gothic.—Early French Gothic vaults merely carried the Norman experiments one step further, by combining with the idea of ribbed and groined vaults the addition of pointed arches,

which still further simplify the construction. The groin ribs were usually left semi-circular, but the cross ribs, being pointed, and springing from the same level, could have their ridges at the same height. Furthermore, the wall arches, by a combination of stilting and pointing, could also be made sufficiently high, although they were so much narrower than either cross or diagonal ribs, and thus, not only was a harmonious wall produced, with ridges nearly level, but also a still further increase in the size of clerestorey windows permitted. In the early Gothic churches of France, the six-part vault was the most popular; *e.g.*, Laon (begun 1160) and Notre Dame, at Paris (begun 1163). By the end of the century, however, the four-part vault completely superseded the earlier type, and with few exceptions in very late work, remained constant throughout the Rayonnant and Flamboyant periods. In general the development was toward more and more level ridges and deeper and slimmer ribs. The web filling is characteristic; formed of slightly arched stone courses, varying in width, in such a manner as to bring the courses generally parallel to the ridge. The web was apparently built without extensive centring, merely using a curved plank under each course, the plank being arranged in two pieces so as to be adjustable in length. The stone cutting of the ribs and supports is of the most perfect type and shows a definite attempt to utilize the material in the most efficient manner. Characteristic is the fact that all the lower courses of the ribs are horizontal instead of radiating and where the ribs come close together they are all cut on one stone, the whole mass forming what is technically known as a *tas de charge*.

Other Continental Gothic.—The Gothic vaults of Germany and Austria were largely based on French forms, until the 15th century, when all sorts of fantastic ribbing came into use. Again the English influence was strong, but instead of keeping the ribs in one plane, as in English work, they were twisted and curved, until their structural basis was well nigh forgotten. The same was true to a less extent of Spanish Gothic, where the bold simplicity of the French type continued in force almost until the dawn of the Renaissance. Italian Gothic vaults were generally large in scale, with ribs unmoulded, or moulded in the simplest possible manner. The cathedral at Florence (nave begun 1357) shows how with structural ideas identical with those of the north, an utterly different effect could be produced, in which, despite the pointed arches the tradition of Roman scale is unmistakably evident.

English Gothic.—The French basis of English Gothic through the work of William of Sens at Canterbury (1175), was soon forgotten through differences in technique that developed. The first of these was a different method of web building; English webs generally consisted of courses of stone, which were equal in width throughout. Thus, due to the curving of the surfaces, they were not parallel to the ridge, and created awkward intersections there. In order to cover this intersection ridge ribs were sometimes introduced. At about the same time intermediate ribs, between cross and diagonals were introduced, which diminished the amount of web that had to be built at one time, and made its construction and support simpler. Thus in the choir of Lincoln cathedral (*c.* 1280) there are no true diagonals and the groin ribs are arranged so that the cross vaults are oblique, with intermediates running from the intersections of the groin ribs to the pier on the other side. Such intermediate ribs are called tiercerons, and in addition to assisting the structural solidity of the vault and its ease of construction, tiercerons became a great source of decorative richness. The climax is seen in the crowded spreading ribs of Exeter cathedral (1292–1367), in which there is one tierceron between each cross and diagonal rib, and two between each diagonal and wall rib. The resultant effect, in which each pier thus carries 11 separate ribs radiating from it, is inexpressibly soaring and graceful. Further richness is gained by the sculptured bosses with rich leafage, which cover the intersections of the ribs.

Later in the 14th century there is a further decorative development through the introduction of small, intermediate ribs, between tiercerons, cross and diagonal ribs, with which intricate patterns are formed. These intermediate ribs are called liernes, and by their use, the spaces between ribs are made so small that they can be covered by two or three slabs of stone. Remarkable examples of this type of vaulting exist at Norwich cathedral (15th century); Winchester (1394–1486) and Gloucester (*c.* 1350).

In Gloucester occurred the first example of the next development—the invention of the fan vault, used in the cloisters (1350–1410). In fan vaulting, each severy, or the section supported on each pier, takes a conoidal shape, so that all of the ribs upon it have approximately the same curvature. Moreover, the ribs are so multiplied and connected by little arches, that the web disappears, except as panelled areas, and the whole vault becomes a homogeneous mass of carefully cut stone. A fan vault, accordingly, is strictly not a ribbed vault at all, but merely a vault consisting of a series of conoids of panelled stone-work intersecting each other. Full advantage was taken of the freedom in line design that this system offered, and all sorts of cusps and other tracery forms were used; there was no limit to the variety of design except the ingenuity of the stone cutter. Fan vaulting reached its climax in the two almost contemporary ceilings in the King's College chapel, Cambridge, and the Henry VII. chapel at Westminster, both completed by 1515. In the former, the vault is simple, with strongly marked cross arches to give it rhythm and definiteness. In the Henry VII. chapel, however, a remarkable variation is found, for the entire vault is supported upon pendents, cut on huge stones that are part of a great cross arch, most of which is concealed. The entire exposed surface is covered with the richest possible traceried panelling, and the line of the cross arches heavily cut. The result forms one of the greatest *tours de force* of stone cutting in the world.

Renaissance.—The great contribution of the Renaissance period to vaulting was its development of the dome (*q.v.*) and especially of the dome on a drum, and with a lantern. This type of design usually necessitated a different curve for the exterior and the interior, and hence the use of domes with two or more shells. The most remarkable example of this type is the dome of S. Peter's at Rome, originally designed by Michelangelo, who completed the drum before his death in 1564, the dome itself being completed by G. della Porta and D. Fontana (1588–90). A remarkable modern instance is the triple dome of the Panthéon in Paris (1764–90) by J. Soufflot, daring in the lightness of its masonry. The greater number of these domes require chains, built in around the base to withstand the thrust.

Another purely Renaissance type of vault is the so-called cove ceiling with penetrations. This consists of a semi-elliptical vault with small cross vaults penetrating its sides, these cross vaults being designed to slope up, with a warped, conical surface, so that their intersections with the main vault, come to a point at the top and take perfect circular or elliptical curves at the sides. This was a favourite type in the Italian Renaissance, as it offered many interesting shapes and surfaces for painted and modelled decoration. Usually a moulding or painted band was carried horizontally along the sides of the vault at the level of the tops of the penetrations. The groins were sometimes decorated with a similar band. One of the most beautiful of such vaults is that over the loggia of the Villa Farnesina, designed by B. Peruzzi (1509–11), and decorated by G. Romano and F. Penni from designs by Raphael (1516–18).

In the Baroque period continuous barrel vaults were the general covering for important palace rooms, frequently built in plaster and non-structural. The decoration consisted in the main of mural paintings surrounded by scrolled and garlanded, curving, modelled frames, gilded, like the vault of the Galérie d'Apollon, in the Louvre at Paris, designed by C. Le Brun, during the reign of Louis XIV., the ceiling painting by E. Delacroix (1849).

Modern.—The two new materials which have most influenced modern vault design are structural terra cotta tile and reinforced concrete. By the use of a thin terra cotta tile, vaults generally domical, have been produced over large halls, with exceedingly slight rise, and with the added advantage of light weight. Similar tiles are also extensively used for the filling or webs of modern versions of the Gothic ribbed vault, in which the ribs are either of cut stone or reinforced concrete. An interesting example of

a tile vault of this type, with nave and choir vaulted with low, pendentive domes, and crossing covered by a dome on a drum, is the chapel of Columbia university, New York.

Concrete without reinforcement is used in the Roman manner by J. F. Bentley in the domes of Westminster cathedral, London, (1895–1903). The introduction of steel reinforcement to take the tensile stresses gave an enormous new freedom to vault design as it allowed the construction of large vaults that would exercise little or no thrust, thus forming a homogeneous arched beam. This quality has been taken advantage of in much recent work, especially on the Continent, as in the Planetarium of the Düsseldorf exposition (1926), by W. Kreis; the flat vault of the church of Notre Dame at Raincy (1924) by Perret Frères; and most remarkable of all, the great dirigible hangar at Orly, near Paris, designed by E. Freyssinet (1916). VAULTING: *see* POLE VAULTING.

VAUQUELIN, LOUIS NICOLAS (1763–1829), French chemist, was born at Hébertot in Normandy on May 16, 1763. He was laboratory boy to an apothecary in Rouen (1777–1779), and after various vicissitudes he obtained an introduction to A. F. Fourcroy, in whose laboratory he was an assistant from 1783–1791. At first his work appeared as that of his master and patron, then in their joint-names; but in 1790 he began to publish on his own authority, and between that year and 1833 his name is associated with 376 papers. Most of these were simple records of patient and laborious analytical operations, in the course of which he detected two new elements—beryllium (1798) in beryl and chromium (1797) in a red lead ore from Siberia. In organic chemistry he is known as the discoverer of quinic acid, asparagine, camphoric acid, and other naturally occurring compounds. He held various offices, and finally succeeded Fourcroy (1809) as professor of chemistry to the Medical Faculty in Paris. He died at his birthplace on Nov. 14, 1829.

He published *Manuel de l'Essayeur,* in 1812.

VAUQUELIN DE LA FRESNAYE, JEAN (1536–1608), French poet, was born at the château of La Fresnaye, near Falaise, in 1536. He studied the humanities at Paris and law at Poitiers and Bourges. He fought in the civil wars under Marshal Matignon and was wounded at the siege of Saint-Lô (1574). Most of his life was spent at Caen, where he was president, and he died there in 1608. La Fresnaye was a disciple of Ronsard, but, while praising the reforms of the Pléiade, he laid stress on the continuity of French literary history. He was a student of the trouvères and the old chroniclers, and desired to see French poetry set on a national basis. These views he expounded in an *Art poétique,* begun in 1574, but not published until 1605.

His *Foresteries* appeared in 1555; his *Diverses poésies,* including the *Art poétique,* the *Satyres françoises,* addressed to various distinguished contemporaries, and the *Idylles,* with some epigrams and sonnets, appeared in 1605. Among his political writings may be noted *Pour la monarchie du royaume contre la division* (1569).

The *Art poétique* was edited by G. Pellissier in 1885. It is summarized for English readers in vol. ii. of George Saintsbury's *History of Criticism.* A notice of the poet by J. Travers is prefixed to an edition of the *Oeuvres diverses* (Caen, 1872).

VAUVENARGUES, LUC DE CLAPIERS, MARQUIS DE (1715–1747), French moralist and miscellaneous writer, was born at Aix in Provence on Aug. 6, 1715. His family was poor though noble; he was educated at the collège of Aix, where he learned little—neither Latin nor Greek—but by means of a translation acquired a great admiration for Plutarch. He entered the army as sub-lieutenant in the king's regiment, and served for more than ten years, taking part in the Italian campaign of Marshal Villars in 1733, and in the disastrous expedition to Bohemia in support of Frederick the Great's designs on Silesia, in which the French were abandoned by their ally. Vauvenargues took part in Marshal Belle-Isle's winter retreat from Prague. On this occasion his legs were frozen, and though he spent a long time in hospital at Nancy he never completely recovered. He was present at the battle of Dettingen, and on his return to France was garrisoned at Arras. His military career was now at an end. He had long been desired by the marquis of Mirabeau, author of *L'Ami des hommes,* and father of the statesman, to turn to literature, but poverty prevented him from going to Paris as his friend wished. He wished to enter the diplomatic service, and made applications to the ministers and to the king himself.

These efforts were unsuccessful, but Vauvenargues was on the point of securing his appointment through the intervention of Voltaire when an attack of smallpox completed the ruin of his health and rendered diplomatic employment out of the question. Voltaire then asked him to submit to him his ideas of the difference between Racine and Corneille. The acquaintance thus begun ripened into real and lasting friendship. Vauvenargues removed to Paris in 1745, and lived there in the closest retirement, seeing but few friends, of whom Marmontel and Voltaire were the chief. Among his correspondents was the archaeologist Fauris de Saint-Vincens. Vauvenargues published in 1746 an *Introduction à la connaissance de l'esprit humain,* with certain *Réflexions* and *Maximes* appended. He died in Paris on May 28, 1747.

The bulk of Vauvenargues's work is small, but its interest great. His real strength is in a department which the French have always cultivated with greater success than any other modern people—the expression in more or less epigrammatic language of the results of acute observation of human conduct and motives, for which he had found ample leisure in his campaigns.

An edition of the *Oeuvres* of Vauvenargues, slightly enlarged, appeared in the year of his death. There were some subsequent editions, superseded by that of M. Gilbert (2 vols., 1857), which contains some correspondence, some *Dialogues of the Dead,* "characters" in imitation of Theophrastus and La Bruyère, and numerous short pieces of criticism and moralizing. The best comments on Vauvenargues, besides those contained in Gilbert's edition, are to be found in four essays by Sainte-Beuve in *Causeries du lundi,* vols. iii. and xiv., and in Villemain's *Tableau de la littérature française au XVIIIme siècle.*

See also M. Paléologue, *Vauvenargues* (1890); *Selections from . . . La Bruyère and Vauvenargues,* with memoir and notes by Miss Elizabeth Lee (1903); E. Gosse, *Three French Moralists* (1918).

VAUXHALL, a district on the south bank of the river Thames, in London, England, included in the metropolitan borough of Lambeth. The manor was held by Falkes de Breauté (whence the name, Falkes hall) in the time of John and Henry III. About 1661 public gardens were laid out here, known as the New Spring garden, and later as Spring gardens, but more familiar under the title of Vauxhall gardens. They soon became the favourite fashionable resort of the metropolis; but as a place of general entertainment they underwent great development from 1732 under the management of Jonathan Tyers (d. 1767) and his sons. In 1822, with the approval of George IV., who frequented the gardens before his accession, the epithet Royal was added to their title. By the middle of the 19th century, however, Vauxhall had lost its high reputation; in 1859 the gardens were finally closed, and the site was quickly built over.

VAUX OF HARROWDEN, THOMAS VAUX, 2ND BARON (1510–1556), English poet, eldest son of Nicholas Vaux, 1st Baron Vaux, was born in 1510. In 1527 he accompanied Cardinal Wolsey on his embassy to France; he attended Henry VIII. to Calais and Boulogne in 1532; in 1531 he took his seat in the House of Lords, and was made Knight of the Bath at the coronation of Anne Boleyn. He was captain of the Isle of Jersey

until 1536. He married Elizabeth Cheney, and died in Oct. 1556. Sketches of Vaux and his wife by Holbein are at Windsor, and a finished portrait of Lady Vaux is at Hampton Court. Two of his poems were included in the *Songes and Sonettes of Surrey* (Tottel's *Miscellany*, 1557). They are "The assault of Cupid upon the fort where the lover's hart lay wounded, and how he was taken," and the "Dittye . . . representinge the Image of Deathe," which the gravedigger in Shakespeare's *Hamlet* misquotes. Thirteen pieces in the *Paradise of Dainty Devices* (1576) are signed by him. These are reprinted in Dr. A. B. Grosart's *Miscellanies of the Fuller Worthies Library* (vol. iv., 1872).

VAVASSOR, in its most general sense a mediate vassal, *i.e.*, one holding a fief under a vassal. The word was, however, applied at various times to the most diverse ranks in the feudal hierarchy, being used practically as the synonym of vassal. Thus tenants-in-chief of the Crown are described by the Emperor Conrad as *valvassores majores* as distinguished from mediate tenants, *valvassores minores*. Gradually the term without qualification was found convenient for describing sub-vassals, tenants-in-chief being called *capitanei* or *barones*. Its implication, however, still varied in different places and times. Bracton ranks the *magnates seu valvassores* between barons and knights; for him they are "men of great dignity," and in this order they are found in a charter of Henry II. (1166). But in the *regestum* of Philip Augustus we find that five vavassors are reckoned as the equivalent of one knight. Finally, Du Cange quotes two charters, one of 1187, another of 1349, in which vavassors are clearly distinguished from nobles.

The derivation of the word vavassor is very obscure. Some would derive it from *vassi ad valvas* (at the folding-doors, *valvae*), *i.e.*, servants of the royal antechamber. Du Cange, with more justice, regards it merely as an obscure variant of *vassus*.

VÄXJÖ, VEXIO or **WEXIÖ,** a town and bishop's see of Sweden, capital of the district (*län*) of Kronoberg, 124 m. north-east of Malmö by rail. Pop. (1928), 9,626. It is pleasantly situated among low wooded hills at the north end of Lake Växjö, and near the south end of Lake Helga. Its appearance is modern, for it was burnt in 1843. The cathedral of St. Siegfrid dates from about 1300, but has been restored, the last time in 1898. The Småland Museum has antiquarian and numismatic collections. At Östrabo, the episcopal residence without the town, the poet Esaias Tegnér died in 1846, and he is buried in the town cemetery.

VAZOFF, IVAN (1850–1921), Bulgarian poet and novelist, was born at Sopot. In common with the founders of Bulgarian literature, Rakovsky, Karaveloff and Botev (*q.v.*), he was first inspired by the sufferings of his countrymen before the liberation. His *Trials of Bulgaria* describes the nation's struggle for freedom. A bard of the people, Vazoff's style is simple and unaffected; his *Epic Poem to the Forgotten,* celebrating the great deeds and sacrifices of the Bulgarian people, thrilled the nation, as also did *Under the Thunder of Victory* (1914), *Songs of Macedonia* (1916) and *New Echo* (1917). Vazoff's most inspired poems and novels of a descriptive character are those relating to the Bulgarian countryside and village life. He died at Sofia on Sept. 22, 1921. His chief novels are: *Under the Yoke* (Eng. trans. 1894); *Svetoslav Terter* (1907), *Hadji Ahil* and *Kazalarskata Tsaritza;* and his dramas include: *Borislav* (1910) and *Towards the Abyss.*

VEBLEN, THORSTEIN B. (1857–), American author and teacher, was born on July 30, 1857. He graduated at Carleton college in 1880, and studied at Johns Hopkins, Yale and Cornell universities. He was appointed reader in political economy at the University of Chicago in 1893, becoming successively instructor and assistant professor. He was associate professor of economics at Stanford university, 1906–09, lecturer in economics at the University of Missouri in 1911–18, and lecturer in the New School for Social Research, New York city, beginning in 1918. For almost ten years he was managing editor of *The Journal of Political Economy.* He was distinguished by his contributions to the theory of economics, especially as modified by current business practices. Among his works are the *Theory of the Leisure Class* (1899); *The Theory of Business Enterprise* (1904); *The Instinct of Workmanship* (1914); *Imperial Germany and the Industrial Revolution* (1915); *The Vested Interests and the State of the Industrial Arts* (1919); *The Engineers and the Price System* (1921); *Absentee Ownership and Business Enterprise in Recent Times* (1923).

VECTOR ANALYSIS. The mathematician and physicist deal with quantities which they find it convenient to classify as either scalar or vector quantities. Familiar examples of scalar quantities are—time, mass, volume, electric charge; and of vector quantities—displacement, velocity, force, electric-field intensity. A scalar quantity is briefly termed a *scalar* and a vector quantity a *vector*, from the Latin "vehere," meaning "to carry."

Vector analysis, of comparatively recent development, was antedated by Quaternions (*q.v.*) originated by Sir William Rowan Hamilton (*q.v.*) in 1843 and *Ausdehnungslehre,* by Hermann Gunther Grassmann in 1844. Of the various forms of vector analysis which have been evolved several find their origin in these subjects. The vector analysis in ordinary use to-day, and reviewed below, is due largely to the work of two mathematical physicists, Josiah Williard Gibbs (*q.v.*), 1881–84, and Oliver Heaviside, 1891. In common with others working in the same field, they recognized the desideratum of developing a system of vector analysis the operational rules of which should conform as far as possible with the corresponding rules of scalar algebra. But, furthermore, each was profoundly interested in producing a system specially adapted to the needs of the mathematical physicist.

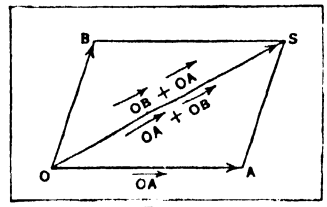

FIG. 1

In what follows, vectors in general, as is customary, will be denoted by letters in Clarendon type and their magnitudes by the same letters in ordinary type: **A**, **B**, **C**, · · · **a**, **b**, **c**; *A*, *B*, *C* · · · *a*, *b*, *c* · · · . The notation used is that introduced by Gibbs.

The simplest type of vector is a line from an initial point (*A*) to a terminal point (*B*) adorned at its terminal point by an arrow-tip to indicate direction. Such a vector is called a *line-vector* or *vector-step* and is conveniently denoted by $\overrightarrow{AB}$. Two vectors of the same kind are considered equal when they are of equal magnitude and have a common direction, their positions in space being otherwise immaterial. Any vector may be represented by a corresponding line-vector with the same direction and a length equal numerically to the magnitude of the vector.

The Addition of Vectors.—Two line-vectors are added in accordance with the "Parallelogram Law":—Referring to fig. 1, let $\overrightarrow{OA}$ and $\overrightarrow{OB}$ be two line-vectors drawn from a common origin *O* and let a parallelogram be constructed upon them as sides; then the line-vector, $\overrightarrow{OS}$ from the origin, *O* to the opposite vertex *S* is by definition the sum or resultant of the two line-vectors and is denoted by $\overrightarrow{OA}+\overrightarrow{OB}$ or by $\overrightarrow{OB}+\overrightarrow{OA}$. Thus

$$\overrightarrow{OS}=\overrightarrow{OA}+\overrightarrow{OB}=\overrightarrow{OB}+\overrightarrow{OA}.$$

If the line-vectors $\overrightarrow{OA}$, $\overrightarrow{OB}$ represent any two vectors **a**, **b** of like kind, then the sum (or resultant) of **a** and **b** is by definition equal in magnitude (numerically) to the line-vector $\overrightarrow{OS}$ and like-directed. Consequently, if **s** denote the sum of **a** and **b**,

$$\mathbf{s}=\mathbf{a}+\mathbf{b}=\mathbf{b}+\mathbf{a}. \qquad (1)$$

The commutative law of addition for two vectors is here expressed.

If a larger number of vectors are to be added, the sum of any two of them may be found as above and added to a third, and so on until the sum of all the vectors is found, the order in which the vectors are added being immaterial.

With the parallelogram law of addition the physicist is particularly pleased for as a matter of experience he knows that when the vectors with which he deals are added in accordance with this law, the sum (in most cases) has a definite physical meaning. For example: The effect upon the motion of a body due to the

action of two forces at some one of its points is the same as would be produced by their resultant or sum as given by the parallelogram law.

Any vector with a negative sign prefixed represents a vector of the same magnitude as the original vector but oppositely directed. It follows that $\mathbf{a}-\mathbf{b}=\mathbf{a}+(-\mathbf{b})$ and hence that the process of subtraction of vectors may be reduced to one of addition.

Multiplication of a vector by a number m simply increases the magnitude of the vector by the factor m with reversal of direction if m be negative. Furthermore, as is easily proved by elementary geometry,

$$m(\mathbf{a}+\mathbf{b}+\cdots)=m\mathbf{a}+m\mathbf{b}+\cdots. \qquad (2)$$

This equation shows that the distributive law of multiplication is valid in the multiplication of a sum of vectors by a number.

The Scalar Product of Two Vectors.—The scalar product of two vectors **a** and **b** is denoted equivalently by $\mathbf{a}\cdot\mathbf{b}$ or $\mathbf{b}\cdot\mathbf{a}$. By definition,

$$\mathbf{a}\cdot\mathbf{b}=\mathbf{b}\cdot\mathbf{a}=ab\cos(\mathbf{a},\mathbf{b}), \qquad (3)$$

where $(\mathbf{a},\mathbf{b})$ denotes the angle between the directions of **a** and **b**. The definition itself makes valid the commutative law of multiplication for the scalar product of two vectors. The distribution law is also valid; for example,

$$(\mathbf{a}+\mathbf{b})\cdot(\mathbf{c}+\mathbf{d})=\mathbf{a}\cdot\mathbf{b}+\mathbf{a}\cdot\mathbf{c}+\mathbf{b}\cdot\mathbf{c}+\mathbf{b}\cdot\mathbf{d}. \qquad (4)$$

The scalar product of two vectors comes naturally into evidence whenever the cosine of the angle between two directions is a matter for discussion.

The Vector Product of Two Vectors.—The vector product of a vector **a** into a vector **b** is denoted by $\mathbf{a}\times\mathbf{b}$. By definition:

$$\mathbf{a}\times\mathbf{b}=\mathbf{n}ab\sin(\mathbf{a},\mathbf{b}), \qquad (5)$$

where **n** is a unit vector perpendicular to **a** and **b** and such that if **a** suffer a rotation about **n** toward **b**, the direction of **n** and that of the rotation would be related as the thrust and twist of a right-handed screw. Accordingly,

$$\mathbf{b}\times\mathbf{a}=-\mathbf{a}\times\mathbf{b}; \qquad (5)$$

and the commutative law of multiplication is not valid in the present case in virtue of the reversal sign. The magnitude of $\mathbf{a}\times\mathbf{b}$ or $\mathbf{b}\times\mathbf{a}$ is numerically equal to the area of a parallelogram constructed upon line-vectors representing **a** and **b**. (*See* fig. 2.)

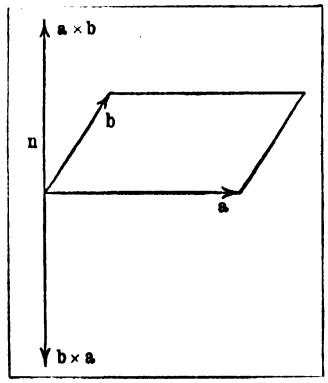

FIG. 2

In the vector multiplication of sums of vectors the distributive law is valid, provided that in expansion the order of the vectors be maintained; for example,

$$(\mathbf{a}+\mathbf{b})\times(\mathbf{c}+\mathbf{d})=\mathbf{a}\times\mathbf{c}+\mathbf{a}\times\mathbf{d}+\mathbf{b}\times\mathbf{c}+\mathbf{b}\times\mathbf{d}. \qquad (7)$$

The vector product of two vectors comes naturally into evidence whenever the sine of the angle between two vectors is under consideration.

The Scalar Triple Product.—An example is furnished by the scalar quantity denoted by $\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}$. Evidently,

$$\mathbf{a}\cdot\mathbf{b}\times\mathbf{c}=\mathbf{a}\cdot\mathbf{n}bc\sin(\mathbf{b},\mathbf{c})=abc\cos(\mathbf{a},\mathbf{n},\sin(\mathbf{b},\mathbf{c})), \qquad (8)$$

where **n** is a unit vector in the direction of $\mathbf{a}\times\mathbf{b}$. In this product cyclical interchange of the vectors may be made and dot and cross may be interchanged without affecting its value; any single non-cyclical interchange of the vectors simply changes the sign of the product. The magnitude of the product is numerically equal to the volume of a parallelepipedon constructed upon line-vectors representing **a**, **b**, **c**.

The Vector Triple Product.—An example is furnished by the vector quantity denoted by $\mathbf{a}\times(\mathbf{b}\times\mathbf{c})$. The following reduction formula is important:

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c})=(\mathbf{a}\cdot\mathbf{c})\mathbf{b}-(\mathbf{a}\cdot\mathbf{b})\mathbf{c}. \qquad (9)$$

Products involving more than three vectors may be formed but are rarely required.

The i, j, k-System of Unit Vectors.—Even after the advent of vector analysis writers on physics (the world of vectors) not infrequently were accustomed (in effect) to evade the vector treatment of vectors with the aid of the familiar Cartesian system of axes. That they were able to do so was due to the fact that three Cartesian scalar equations are equivalent to one vector equation. When used to supplement the vectorial treatment of vectors, and not to avoid it, Cartesian reference axes have a very useful place in vector analysis.

Let **i**, **j**, **k** be three line-vectors each of unit length in the positive directions of the X, Y, Z-axes of a rectangular Cartesian system. Then, in virtue of (3) and (5):

$$\mathbf{i}\cdot\mathbf{i}=\mathbf{j}\cdot\mathbf{j}=\mathbf{k}\cdot\mathbf{k}=1, \qquad \mathbf{i}\cdot\mathbf{j}=\mathbf{j}\cdot\mathbf{k}=\mathbf{k}\cdot\mathbf{i}=0; \qquad (10)$$

$$\mathbf{i}\times\mathbf{i}=\mathbf{j}\times\mathbf{j}=\mathbf{k}\times\mathbf{k}=0, \qquad \mathbf{i}\times\mathbf{j}=\mathbf{k}.\mathbf{j}\times\mathbf{k}=\mathbf{i},\ \mathbf{k}\times\mathbf{i}=\mathbf{j}, \qquad (11)$$

Two vectors, **a** and **b**, may be expressed in the forms

$$\mathbf{a}=a_1\mathbf{i}+a_2\mathbf{j}+a_3\mathbf{k}, \qquad (12)$$

$$\mathbf{b}=b_1\mathbf{i}+b_2\mathbf{j}+b_3\mathbf{k}, \qquad (13)$$

where $a_1\mathbf{i}$, $a_2\mathbf{j}$, $a_3\mathbf{k}$ and $b_1\mathbf{i}$, $b_2\mathbf{j}$, $b_3\mathbf{k}$ are the vector components of **a** and **b** parallel to the X, Y, Z-axes and a_1, a_2, a_3 and b_1, b_2, b_3 are the scalar values of these components. Then

$$\mathbf{a}+\mathbf{b}(a_1+b_1)\mathbf{i}+(a_2+b_2)\mathbf{j}+(a_3+b_3)\mathbf{k}. \qquad (14)$$

In like manner the sum of any number of vectors may be expressed as a sum of **i**, **j**, **k**-components.

In virtue of (10) and the distributive law for the scalar product of vectors,

$$\mathbf{a}\cdot\mathbf{b}=(a_1\mathbf{i}+a_2\mathbf{j}+a_3\mathbf{k})\cdot(b_1\mathbf{i}+b_2\mathbf{j}+b_3\mathbf{k})=a_1b_1+a_2b_2+a_3b_3. \qquad (15)$$

In particular, if $\mathbf{b}=\mathbf{a}$,

$$\mathbf{a}\cdot\mathbf{a}=a^2=a_1^2+a_2^2+a_3^2. \qquad (16)$$

The vector product of **a** into **b**, in virtue of (11) and the distributive law for vector products, may be expressed as follows:

$$\begin{aligned}\mathbf{a}\times\mathbf{b}&=(a_1\mathbf{i}+a_2\mathbf{j}+a_3\mathbf{k})\times(b_1\mathbf{i}+b_2\mathbf{j}+b_3\mathbf{k})\\&=(a_2b_3-a_3b_2)\mathbf{i}\\&+(a_3b_1-a_1b_3)\mathbf{j}\\&+(a_1b_2-a_2b_1)\mathbf{k}.\end{aligned} \qquad (17)$$

Vector Fields.—A region of space with each point of which is associated a vector is called a *vector field*. Examples of such are the gravitational, electric and magnetic fields of the physicist. In the theory of such fields the behaviour of a vector in the neighbourhood of any point is a matter for investigation. The attention being fixed upon a particular point $P(x, y, z)$, let the vector **v** associated with the point be expressed in the form:

$$\mathbf{v}=v_1\mathbf{i}+v_2\mathbf{j}+v_3\mathbf{k}, \qquad (18)$$

where the scalar values of the vector components, v_1, v_2, v_3, are now to be regarded as functions of the co-ordinates x, y, z. Let $x+dx$, $y+dy$, $z+dz$ be the co-ordinates of any neighbouring point where dx, dy, dz represent infinitesimal increments of x, y, z. Then, if $d\mathbf{v}$ represent the infinitesimal increment in the vector **v** corresponding to the increments of the co-ordinates, where dv_1,

$$d\mathbf{v}=\mathbf{i}dv_1+\mathbf{j}dv_2+\mathbf{k}dv_3, \qquad (19)$$

dv_2, dv_3 represent the infinitesimal increments in v_1, v_2, v_3 corresponding to the increments of the co-ordinates, and which may be expressed (*see* CALCULUS) as follows:

$$\begin{aligned}dv_1&=\frac{\partial v_1}{\partial x}dx+\frac{\partial v_1}{\partial y}dy+\frac{\partial v_1}{\partial z}dz,\\dv_2&=\frac{\partial v_2}{\partial x}dx+\frac{\partial v_2}{\partial y}dy+\frac{\partial v_2}{\partial z}dz,\\dv_3&=\frac{\partial v_3}{\partial x}dx+\frac{\partial v_3}{\partial y}dy+\frac{\partial v_3}{\partial z}dz,\end{aligned} \qquad (20)$$

where the symbol $\frac{\partial v_1}{\partial x}$ denotes the rate at which the function v_1 would increase with respect to x if x be varied while y and z are held constant; and the other coefficients of the co-ordinate increments have an analogous significance. In all there are nine coefficients of this sort and in terms of them the character of the vector field in the neighbourhood of P can be completely specified.

The Divergence and the Curl of a Vector.—Two quantities of fundamental importance in the theory of vector fields will now be defined in terms of these coefficients.

One of these is a scalar called the *divergence* of **v** (div **v**) and defined by the equation

$$\text{div } \mathbf{v} = \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y} + \frac{\partial v_3}{\partial z} \qquad (21)$$

The other is a vector called the *curl* of **v** (curl **v**) and defined by the equation:

$$\text{curl } \mathbf{v} = \left(\frac{\partial v_3}{\partial y} - \frac{\partial v_2}{\partial z}\right)\mathbf{i} + \left(\frac{\partial v_1}{\partial z} - \frac{\partial v_3}{\partial x}\right)\mathbf{j} + \left(\frac{\partial v_2}{\partial x} - \frac{\partial v_1}{\partial y}\right)\mathbf{k}. \qquad (22)$$

The values of both these quantities can be shown to be independent of the particular set of **i**, **j**, **k**-axes used in their definitions.

If **v** represents the velocity of a moving fluid and ρ represents its density at any given point then $\rho\mathbf{v}$ is its momentum per unity volume; div $\rho\mathbf{v}$ is a measure of the rate at which the fluid is leaving the neighbourhood of the point reckoned per unit volume; curl **v** is a measure of the vortical motion of the fluid. In fig. 3, for a case of two dimensional flow, is shown, diagrammatically by means of arrows representing the velocity vector, the flow of a fluid in the vicinity of four points P, P', Q, Q'. At the points P and P' a finite divergence of the velocity is indicated (+ at P and − at P'); at Q and Q' a finite value of the curl of the velocity is indicated (clockwise at Q and counter-clockwise at Q').

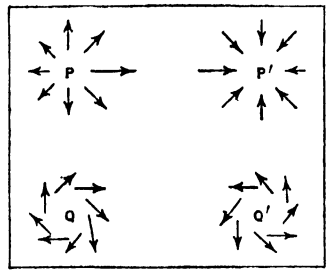

FIG. 3

If **v** denotes the magnetic field intensity at any point (the force which would act upon a positive unit magnetic pole if placed at the point) in a magnetic field due to a distribution of electric currents, then curl **v** is a measure of the electric current density (current per unit area) at the point.

Scalar and Vector Potential Functions.—If throughout a given region curl **v** = o or div **v** = o, then, as the case may be, **v** is said to have a *lamellar* or *solenoidal distribution* in the region.

In the case of a lamellar distribution (curl **v** = o) it is possible to derive **v** from a scalar function V of the co-ordinates x, y, z in accordance with the equation

$$\mathbf{v} = \mathbf{i}\frac{\partial V}{\partial x} + \mathbf{j}\frac{\partial V}{\partial y} + \mathbf{k}\frac{\partial V}{\partial z}, \qquad (23)$$

and **v** is called the *gradient* of V, often abbreviated to grad V or ∇V. The gradient of V is a vector with a direction determined by that of the greatest space rate of increase of V and a magnitude equal to this rate of increase.

The function V is called a *scalar potential function.*

In the case of a solenoidal distribution (div **v** = o) it is possible to derive **v** from a vector function **G** of the co-ordinates in accordance with the equation:

$$\mathbf{v} = \text{curl } \mathbf{G}. \qquad (24)$$

The function **G** is called a *vector potential function.*

Linear Vector Functions.—Let two vectors **p** and **q** associated with a point (x, y, z) be expressed in terms of their **i**, **j**, **k**-components as follows:

$$\mathbf{p} = p_1\mathbf{i} + p_2\mathbf{j} + p_3\mathbf{k}, \qquad (25)$$

$$\mathbf{q} = q_1\mathbf{i} + q_2\mathbf{j} + q_3\mathbf{k}, \qquad (26)$$

and suppose the two vectors, so related that:

$$\begin{aligned} q_1 &= a_{11}p_1 + a_{12}p_2 + a_{13}p_3, \\ q_2 &= a_{21}p_1 + a_{22}p_2 + a_{23}p_3, \\ q_3 &= a_{31}p_1 + a_{32}p_2 + a_{33}p_3, \end{aligned} \qquad (27)$$

where the a-coefficients are constants or, possibly, functions of the co-ordinates x, y, z. Then **q** is called a *linear vector function* of **p**. The theory of such functions constitutes one of the most important branches of vector analysis.

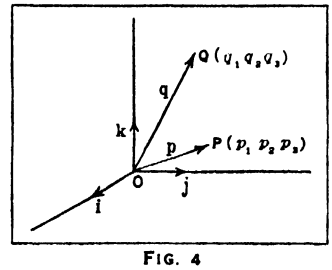

FIG. 4

By way of example, the vector **p** may represent the position vector of any point P of a material body with respect to an arbitrary point O fixed in the body. If we now suppose the body to undergo a strain, the point of the body originally at P will in general occupy a new position Q (*see* fig. 4) with position vector **q** relative to O. If the strain is of the type known as homogeneous then **q** will be a linear vector function of **p**. The scalar coefficients p_1, p_2, p_3 and q_1, q_2, q_3 of **i**, **j**, **k** in equations (25) and (26) respectively will then be the rectangular co-ordinates of P and Q respectively on an **i**, **j**, **k**-system of axes with origin at O. The precise nature of the homogeneous strain will be determined by the values of the nine a-coefficients in equations (27). In a homogeneous strain the coefficients are constants; straight lines remain straight and parallel lines remain parallel.

Among mathematical subjects having contacts with vector analysis, the more important are: The various geometries, determinants, multiple algebra and in particular, tensor theory—the basis of the mathematical exposition of the general theory of relativity. The easiest approach to tensor theory is probably by way of vector analysis.

VEDANTA PHILOSOPHY: *see* INDIAN PHILOSOPHY.

VEDDAS or **WEDDAS,** a primitive people of Ceylon. During the Dutch occupation (1644–1796) they were found as far north as Jaffna, but are now confined to the south-eastern district. They are divided into Veddas, Village Veddas and Coast Veddas. They speak Sinhalese, greatly modified with a few words possibly of their original language.

The true Veddas are short (average 60⅜ in.). They are dark-skinned and flat-nosed, with small skulls. The brow ridges are well marked. Their black hair is long, wavy, almost curly. They live chiefly by hunting; catch fish by poisoning the water, are skilled in getting wild honey; use bows with iron-pointed arrows and breed hunting dogs. They dwell in caves or bark huts. They count on their fingers, and make fire with the fire-drill twirled by hand. They are divided into matrilineal exogamic clans. They are monogamous. Their religion is essentially a cult of the dead.

See C. G. and B. Z. Seligmann, *The Veddas* (1911).

VEDDER, ELIHU (1836–1923), American painter, was born in New York city, Feb. 26, 1836. He studied under the genre and historical painter Tompkins H. Matteson (1813–84), at Sherburne, N.Y., later under Picot, in Paris, and then, in 1857–61, in Italy. After 1867 he lived in Rome, making occasional visits to America. He was elected to full membership in the National Academy of Design, New York, in 1865. He devoted himself to the painting of genre pictures, which, however, attracted only modest attention until the publication, in 1884, of his illustrations to the *Rubaiyat* of Omar Khayyám; these immediately gave him a distinguished place in the art world. Important decorative work

came at a later date, more particularly the painting symbolizing the art of the city of Rome, in the Walker Art Gallery of Bowdoin College, Maine, and the five lunettes (in the entrance hall) symbolical of government, and the mosaic "Minerva" in the Congressional Library at Washington. He died in Rome, Jan. 29, 1923. A few days before his death, his book, *Doubt and Other Things,* was published.

VEERE, a town in the province of Zeeland, Holland, on the island of Walcheren 4 m. N.N.E. of Middelburg, with which it is connected by canal (1867–72). Pop. (1927) 9,089. It contains several interesting architectural remains of the days of its former prosperity, when it was an important commercial centre.

VEERY (*Hylocichla fuscescens*), also called Wilson's thrush, a well-known bird of the thrush family (Turdidae) inhabiting eastern North America, where it breeds from New Jersey and Illinois north to Newfoundland and Manitoba; a subspecies, the willow thrush (*H. f. salicicola*), inhabits the Rocky mountains as far north as British Columbia, extending east to the Dakotas and Newfoundland. Both forms winter in Central America, the willow thrush, however, also going as far south as southern Brazil. About 7½ in. long, the veery is a uniform cinnamon brown above, white below, with greyish sides and a buff throat and breast faintly spotted with cinnamon brown. It has a fine song rich in overtones. The veery lives mainly in woods and feeds largely on insects.

VEGA, GARCILASO DE LA (1503–1536), Spanish soldier and poet, was born at Toledo. At the age of 17 he was attached to the bodyguard of Charles V., fought against the insurgent *communeros,* and afterwards gained great distinction by his bravery at the battle of Pavia (1525). In 1526 he married a lady-in-waiting to Queen Eleanor. He took part in the repulse of the Turks from Vienna in 1529, was present at the coronation of the emperor at Bologna in 1530, and was charged with a secret mission to Paris in the autumn of the same year. In 1531 he accompanied the duke of Alva to Vienna, where, for conniving at the clandestine marriage of his nephew to a maid-of-honour, he was imprisoned on an island in the Danube. During this captivity he composed the fine cancion, "Con un manso ruido de agua corriente y clara." Released and restored to favour in June 1532, he went to Naples on the staff of Don Pedro de Toledo, the newly appointed viceroy, by whom he was twice sent on public business of importance to Barcelona, in 1533 and 1534. After having accompanied the emperor on the expedition to Tunis (1535), he took part with him in the invasion of Provence and was mortally wounded while storming a fort at Muy, near Fréjus. His poems, which are among the finest in their language, include three pastorals, which rank among the finest in the Spanish language, 37 sonnets, five canciones, two elegies, and a blank verse epistle, all influenced by Italian models. An English translation was published by J. H. Wiffen in 1823. Garcilaso's delicate charm has survived all changes of taste, and by universal consent he ranks among the most accomplished and artistic of Spanish poets.

See H. Keniston, *Garcilaso de la Vega* (1922–25).

VEGA, GARCILASO DE LA, called "Inca" (*c.* 1535–1616), historian of Peru, was born at Cuzco. His father, Sebastiano Garcilaso (d. 1559), was a cadet of the illustrious family of La Vega, who had gone to Peru in the suite of Pedro de Alvarado, and his mother was of the Peruvian blood-royal, a circumstance of which he was very proud as giving him a right to the title which he claimed by invariably subscribing himself "Inca." About 1560 he removed to Spain, but failed to win the preferment for which he hoped. After long service in the army, he turned to literature, solacing himself in his rather meagre circumstances by depicting the riches of the new world. He died in Spain in 1616. He published in 1590 a translation of *Dialoghi di Amore* of Léon Hebro, but his fame depends upon *La Florida del Ynca* (1605) and his history of Peru (Pt. 1, *Commentarios Reales que tratan del origen de los Yncas,* Lisbon, 1608 or 1609; Pt. 2, Cordova, 1617). This latter work has been translated into English, French, German and Italian and has been utilized by Robertson, Prescott, Marmontel and Sheridan. The former work, a history of the De Soto expedition, was long regarded primarily as fiction. In spite of its exaggerations as to the numbers and wealth of the Indians, recent investigations have shown it to possess more ethnological value than had been hitherto supposed. Garcilaso de la Vega wrote before history was regarded as a science; by temperament and circumstances he was inclined to the romantic; nevertheless his work possesses permanent intrinsic interest and he will be remembered as the first South American in Spanish literature.

See the monograph by Julia Fitzmaurice-Kelly (1921) in the Hispanic series, and the Lima edition of the Peruvian history (1918–21) prepared by H. H. Urteaga with an introduction by Don José de la Riva Agüero.

VEGA, the bright star in the constellation Lyra (*q.v.*), hence its Bayer equivalent, α Lyrae; its magnitude is 0·14, and it is the fourth brightest star in the sky and the brightest in the northern hemisphere.

VEGA CARPIO, LOPE FELIX DE (1562–1635), Spanish dramatist and poet, was born in Madrid. His father and mother, Felices de Vega and Francisca Hernandez Flores, originally came from the valley of Carriedo in Asturias. Lope began his studies at the Theatine college in Madrid, and afterwards entered the service of Don Jerónimo Manrique, bishop of Avila, who sent him to the University of Alcalá de Henares, perhaps from 1577–81. He took part in the expedition to the Azores in 1582, and from 1583–87 was secretary to the marqués de las Navas. In Feb. 1588 he was banished for circulating criminal libels against his mistress, Elena Osorio, whom he has celebrated under the name of Filis. He defied the law by returning to Madrid soon afterwards and eloping with Isabel de Urbina, sister of Philip II.'s herald; he married her by proxy on May 10, 1588, and joined the Invincible Armada, losing his brother in one of the encounters in the Channel. He settled for a short while at Valencia, where he made acquaintance with a circle of young poets who were afterwards to be his ardent supporters in founding the new comedy. He joined the household of the duke of Alva, with whom he remained till 1595. Soon afterwards he lost his wife. He was prosecuted for criminal conversation in 1596, became secretary to the marquis de Malpica (afterwards count of Lemos), and in 1598 married a second wife, Juana de Guardo, by whom he had two children (Carlos, who died in 1612, and Feliciana Felix); but she died, shortly after giving birth to the latter, in 1613. Lope then sought a refuge in the church. After having been affiliated to a tertiary order, he took priest's orders.

At this juncture, about 1614, he was in the very zenith of his glory. A veritable dictator in the Spanish world of letters, he wielded over all the authors of his nation a power similar to that which was afterwards exercised in France by Voltaire. At this distance of time Lope is to us simply a great dramatic poet, the founder of the Spanish theatre; but to his contemporaries he was much more. His epics, his pastorals, his odes, his sonnets, now forgotten, all placed him in the front rank of authorship. Such was his prestige that he dealt with his noble patrons almost on a footing of equality. The duke of Sessa in particular, his Maecenas from 1605 onwards, was also his personal friend, and the tone of Lope's letters to him is one of frank familiarity, modified only by some forms of deference. Lope's fame, too, had travelled abroad; foreigners of distinction passing through Madrid made a point of visiting him; papal legates brought him the compliments of their master; in 1627 Urban VIII., a Barberini, sent him the diploma of doctor of theology in the Collegium Sapientiae and the cross of the order of St. John of Jerusalem (whence the poet's titles of "Doctor" and "Frey"). His last days were full of sadness; the death of his son Lope, the elopement of his daughter, Antonia Clara, wounded him to the soul. Montalban tells us that every Friday the poet scourged himself, so severely that the walls of his room were sprinkled with his blood. His death, on Aug. 27, 1635, was followed by national mourning.

For a rapid survey of the works of Lope, it is convenient to begin with those which the Spaniards include under the name of *Obras Sueltas,* the title of the large collection of the poet's non-dramatic works (1776–79). We shall enumerate the most important of these, as far as possible in the order of publication. The *Arcadia* (1598), a pastoral romance, inspired by Sannazaro, is one of the poet's most wearisome productions. *La Dragontea*

(1598), is a fantastic history in verse of Sir Francis Drake's last expedition and death. *Isidro* (1599), a narrative of the life of Isidore, patron of Madrid, is called a Castilian poem on account of the rhythm in which it is composed—*quintillas* of octosyllabic verse. The *Hermosura de Angélica* (1602), in three books, is a sort of continuation of the *Orlando Furioso,* in octaves after the fashion of the original poem. Finally, the *Rimas* are a miscellany of short pieces. In 1604 was published the *Peregrino en su Patria,* a romance similar in kind to the *Aethiopica* of Heliodorus. Having imitated Ariosto, he proceeded to imitate Tasso; but his *Jerusalen Conquistada* (1609) has preserved nothing of the art shown in its model and is an insipid performance. Next follows the *Pastores de Belen* (1612) a pious pastoral, dedicated to his son Carlos, which forms a pendant to his secular *Arcadia;* and incidental pieces published in connection with the solemnities of the beatification and canonization of St. Isidore in 1620 and 1622. It is enough to mention *La Filomena* (1621), *La Circe* (1624) and other poems published about the same date, as also the four prose novels, *Las Fortunas de Diana, El Desdichado por la Honra, La Más Prudente Venganza* and *Guzmán el Bravo.* The great success of the *Novelas exemplares* (1613) of Cervantes had stimulated Lope, but his novels have none of the grace, naturalness, or interest which characterize those of his rival. The last important work which has to be mentioned before we leave the narrative poetry of Lope is the *Laurel de Apolo* (1630). This piece describes the coronation of the poets of Spain on Helicon by Apollo, and it is more meritorious as a bibliographical manual of Spanish poetry at that time than as genuine poetry. One other *obra suelta,* closely akin to Lope's dramatic works, though not, properly speaking, a drama, is *La Dorotea* (1632). Lope describes it as an "action in prose," but it is rather a "romance in dialogue"; for, although divided into acts, the narrative is dramatic in form only. Of all Lope's productions *Dorotea* shows most observation and study; the style also is unusually simple and easy. Of all this mass of *obras sueltas,* filling more than 20 volumes, very little (leaving *Dorotea* out of account) holds its own in the judgment of posterity. The lyrical element alone retains some vitality. From the *Rimas* and other collections of detached pieces one could compile a pleasing anthology of sonnets, epistles, elegies and romances, to which it would be proper to add the *Gatomaquia,* a burlesque poem published along with other metrical pieces in 1634 by Lope under the pseudonym of Tomé de Burguillos.

It is, however, to his dramatic writings that Lope owes his eminent place in literary history. It is very curious to notice how he himself always treats the art of comedy-writing as one of the humblest of trades (*de pane lucrando*), and protests against the supposition that in writing for the stage his aim is glory and not money. The reason is not far to seek. The Spanish drama, which, if not literally the creation of Lope, at least owes to him its definitive form—the three-act comedy—was totally regardless of the precepts of the school, the pseudo-Aristotelianism of the doctors of the period. Lope accordingly, who stood in awe of the criticism of the *científicos,* felt bound to prove that, from the point of view of literary art, he attached no value to the "rustic fruits of his humble *vega.*" In his *Arte Nuevo de hacer comedias en este tiempo* (1609), Lope begins by showing that he knows as well as any one the established rules of poetry, and then excuses himself for his inability to follow them on the ground that the "vulgar" Spaniard cares nothing about them. "Let us then speak to him in the language of fools, since it is he who pays us." Another reason which made it necessary for him to speak deprecatingly of his dramatic works is the circumstance that the vast majority of them were written in haste and to order. The poet does not hestitate to confess that "more than a hundred of my comedies have taken only 24 hours to pass from my brain to the boards of the theatre." Nevertheless, Lope did write dramas in which the plan is more fully matured and the execution more carefully carried out; still, hurried composition and reckless production are after all among the distinctive marks of his theatrical works. Towards the close of his career Lope somewhat modified the severe and disdainful judgments he had formerly passed upon his dramatic performances; he seems to have had a presentiment that posterity, in spite of the grave defects of his work in that department, would nevertheless place it much higher than *La Dragontea* and *Jerusalen Conquistada,* and other works of which he himself thought so much. We may certainly credit Lope with creative power, with the instinct which enabled him to reproduce the facts of history or those supplied by the imagination in a multitude of dramatic situations with an astonishing cleverness and flexibility of expression; but unfortunately, instead of concentrating his talent upon the production of a limited number of works which he might have brought to perfection, he dissipated it, so to say, and scattered it to the winds.

The classification of the enormous mass of Lope's plays (about 470 *comedias* and 50 *autos* are known to us) is a task of great difficulty, inasmuch as the terms usually employed, such as comedy, tragedy, and the like, do not apply here. There is not explicitness enough in the division current in Spain, which recognizes three categories:—(1) *comedias de capa y espada,* the subjects of which are drawn from everyday life and in which the persons appear as simple *caballeros;* (2) *comedias de ruido* or *de teatro,* in which kings and princes are the leading characters and the action is accompanied with a greater display of dramatic machinery; (3) *comedias divinas* or *de santos.* Some other arrangement must be attempted. In the first place, Lope's work belongs essentially to the drama of intrigue; be the subject what it may, it is always the plot that determines everything else. Lope in the whole range of his dramatic works has no piece comparable to *La Verdad Sospechosa* of Ruiz de Alarcon, the most finished example in Spanish literature of the comedy of character; and the comedy of manners is represented only by *El Galan Castrucho, El Anzuelo de Fenisa* and one or two others. It is from history, and particularly Spanish history, that Lope has borrowed more than from any other source. But it is to the class of *capa y espada* —also called *novelesco,* because the subjects are almost always love intrigues complicated with affairs of honour—that Lope's most celebrated plays belong. In these he has most fully displayed his powers of imagination (the subjects being all invented) and his skill in elaborating a plot. Among the plays of this class which are those best known in Europe, and most frequently imitated and translated, may be specially mentioned *Los Ramilletes de Madrid, La Boba para los Otros y Discreta para si, El Perro del Hortelano, La Viuda de Valencia* and *El Maestro de Danzar.* In some of them Lope has sought to set forth some moral maxim, and illustrate its abuse by a living example, as in *Las Flores de Don Juan.* Such pieces are, however, rare in Lope's repertory; in common with all other writers of his order in Spain, with the occasional exception of Ruiz de Alarcon, his sole aim is to amuse and stir his public; not troubling himself about its instruction. The strong point of such writers is and always will be their management of the plot.

To sum up, Lope found a poorly organized drama, plays being composed sometimes in four acts, sometimes in three; and, though they were written in verse, the structure of the versification was left far too much to the caprice of the individual writer. The style of drama then in vogue he adopted, because the Spanish public liked it. The narrow framework it afforded he enlarged to an extraordinary degree, introducing everything that could possibly furnish material for dramatic situations—the Bible, ancient mythology, the lives of the saints, ancient history, Spanish history, the legends of the middle ages, the writings of the Italian novelists, current events, Spanish life in the 17th century. Before him manners and the conditions of persons and characters had been barely sketched; with fuller observation and more careful description he created real types, and gave to each social order the language and drapery appropriate to it. The old comedy was awkward and poor in its versification; he introduced order into the use of all the forms of national poetry, from the old romance couplets to the rarest lyrical combinations borrowed from Italy. Hence he was justified in saying that those who should come after him had only to go on along the path which he had traced.

VEGETABLE, a word used as a general term for plants (*q.v.*), and specifically, in popular language, for such plants as can be eaten by man or animals, whether cooked or raw, and whether the whole of such plants are edible, or only the leaves or the roots or tubers. Among such edible or culinary plants or portions of plants, a further distinction is made popularly between "fruits" and "vegetables," for which *see* FRUIT.

For the botany of vegetables *see* under the specific names, *e.g.,* POTATO, TURNIP, etc., and also HORTICULTURE, generally.

Vegetable Culture in the United States.—Vegetables are grown in greater or less variety in every State. The chief sources of production are home gardens, truck farms and greenhouses in the vicinity of large cities, farms devoted to raising vegetables for canning and other manufacture, and also farms in the Southern States and in California for the production of winter and early spring vegetables for northern and eastern markets.

The accompanying table, prepared from reports in the *U.S. Yearbook of Agriculture,* gives statistics regarding the more important vegetables grown for the market. In addition, artichokes, beets, broccoli, Brussels sprouts, radishes, rhubarb, squashes, turnips and other minor vegetables are grown commercially, but mostly to a much smaller extent in the country as a whole, though some are locally of considerable importance.

VEGETABLE COOKERY. The term "vegetables" other than pulses and cereals (*qq.v.*) covers those plants which have edible flowers, fruit or seed, stalks, roots or leaves. Green vegetables are valuable in the diet chiefly on account of their potassium salts and vitamines, cellulose, which supplies the body with bulk or "roughage," thus assisting digestion; and for their water content (average 90–95%). Roots and tubers are heat- and energy-giving foods. The cellulose of vegetables is valuable as roughage in the intestinal tract.

Green Vegetables.—There are three distinct methods of cooking green vegetables. Steaming is one. In the second, only enough water is used to prevent the vegetables from sticking to the pan and getting burnt, and the aim is to conserve the natural salts and flavours of the vegetables. The third and more common method of cooking ordinary "greens" is to boil the vegetable in a pan of fast-boiling salted water with the lid off. Soda is frequently added to soften the water and preserve the colour but it destroys the vitamines and is not recommended.

All these methods can be used for most green vegetables with the exception of sorrel and spinach, which have a very high water content and require very little water in cooking.

To cook cabbage first wash well in salt and water to get rid of any insects, trim off outside discoloured leaves and put into a kettle full of boiling water, with at least 1 teaspoon salt to each qt. To lessen odor of cooking, do not cover. Whole young cabbage, 25–30 min., old, 30 min.–1 hr. Quartered, 10–15 min. Leaves, 5–10 min. Drain, add 1 tablespoon butter for each lb.

Cabbage may be stuffed with forcemeat (*see* FORCEMEATS) or savoury rice (cooked rice and grated cheese, chopped onion and seasoning) by separating the leaves from a parboiled cabbage and rolling each leaf round the forcemeat, or the stuffing may be placed in the centre of the cabbage. If the cabbage is rolled stew in a thickened gravy.

Brussels sprouts may be dipped in batter and fried. Single leaf vegetables, *e.g.*, spinach, beet-tops, etc., may be cooked until tender, drained and passed through a sieve, then mixed with butter, cream, seasoning, and formed into a purée which can be garnished with hard-boiled eggs or served on toast. Green purée soups are made from green vegetables. For cooking of French beans, scarlet runner beans, peas, etc., *see* PULSES. It is important to avoid the overcooking of vegetables.

White Vegetables.—To prepare white vegetables for cooking wash, scrub or scrape. Celery should be cut up in thin strips lengthwise to facilitate cooking. Have ready a pan of salted boiling water, squeeze into it a little lemon juice to keep the vegetables a good colour. In cooking certain blanched vegetables, *e.g.*, asparagus, leeks, etc., it is best to tie the vegetables in bundles. Overcooking of all white vegetables should be avoided. As a rule, 15–30 minutes (according to the age and type of vegetable being boiled) is sufficient time to allow.

Jerusalem artichokes, salsify (oyster plant), etc., may be passed through a sieve and creamed, sprinkled with grated cheese and sauce and then baked au gratin. They may also be fried in batter as fritters. Celery can be stewed in milk or brown sauce, or served au gratin. Seakale and asparagus are usually served with melted butter but may be served with other sauces, mayonnaise, etc. All white vegetables may be made into soup by passing through a sieve, thickening and mixing with milk.

Potatoes.—There are innumerable ways of cooking potatoes but for most potato dishes they must be first plain boiled. To boil in their skins, clean thoroughly and place in boiling salted water. Simmer until tender (about 30–40 minutes; but *see* note in COOKERY on boiling at high altitudes); drain off the water and allow them to steam in the pan for five minutes with the lid on. Remove the lid, allow the steam to escape for a few seconds and use as required.

To bake potatoes bake them in their skins or peel and put in a baking-dish with sufficient fat to keep them from burning and place under a piece of roasting meat so that the fat from the meat can drip on to them and so keep them moist while cooking.

Mashed potatoes are plain boiled or steamed, mashed with butter and milk, and then beaten with a wooden spoon until creamy. Potatoes may be fried either in a frying-pan, or in a pan of deep fat. Before frying thoroughly dry; then after slicing, cut into strips or fancy shapes. To cream potatoes for vegetarian dishes add eggs, cream or sauce to mashed potatoes and bake or steam as a soufflé.

VEGETABLE MARROW, botanically a variety of *Cucurbita Pepo,* the most important of the gourds (*q.v.*), used as an esculent, furnishing in good seasons a very large supply for the table. They are best when eaten quite young and not overboiled, the flesh being then tender, and the flavour sweet and nutty. The custard marrows (scallop or patty-pan varieties), bear a peculiar-looking flattened fruit with scalloped edges, which has a sweeter and less nutty flavour than the true marrow. The bush marrows are more bushy in habit and taller and more sturdy in growth.

Vegetable marrows require a warm situation and a rich soil free from stagnant moisture. They do well on a rubbish or old-dung heap, or in a warm border on little hillocks made up with any fermenting material, to give them a slight warmth at starting. The seeds should be sown in a warm pit in April, and forwarded under glass, but in a very mild heat; the plants must be shifted into larger pots, and be gradually hardened previous to being planted out, when the mild weather sets in in May or June. The seeds may be sown early in May in pots under a hand-glass, or towards the end of May in the open ground, if heat is not at command. The shoots may be allowed to run along the surface of the ground, or they may be trained against a wall or paling, or on trellises.

The tropical *Blighia sapida* (Sapindaceae), which is cultivated for its edible fruits, is also known as vegetable marrow.

VEGETARIANISM, a word which came into use about the year 1847, as applied to the practice of living upon foods from which fish, flesh and fowl are excluded. There have from time to time been various sects or schools of thought that have advocated narrower views. Some of these have excluded all animal products —such as milk and eggs and cheese. Some have excluded all cooked foods, and have preached the virtues of fruits and nuts and grains in their natural ripe state. Some have abstained from all underground-grown roots and tubers, and have claimed special benefits from using only those fruits and vegetables that are grown in the sunlight. Some have given up all grain and pulse foods, and have declared that old age can be best resisted by living entirely upon fruits, salads, nuts, soft water and milk products. Some have added fish to their dietary; but, speaking generally, all who are called vegetarians will be found to abstain from the use of flesh and fowl and almost invariably also from fish as food.

The fact, however, must not be overlooked that while vegetarian societies claim as "vegetarians" all who abstain from flesh foods, there is a large and growing number of people who repudiate the name of "vegetarian" because of its associations, but who none the less, for some of the reasons detailed below, abstain from eating anything that has been killed.

The reasons that are advanced for the practice of fruitarianism or vegetarianism are very comprehensive, but the chief are the

following:—

1. *Health.*—(α) On the ground that animals are affected by diseases which are communicable, and are actually communicated, to man by the ingestion of their flesh, *e.g.*, parasites, tuberculosis; (β) on the ground that the flesh of artificially fed animals is full of excretory substances, and that, therefore, *under modern conditions*, flesh-eating is injurious, and may be the cause of excretory substance and uric acid deposits or rapid tissue-destroying diseases in man; *e.g.*, gout, cancer.

2. *Economy.*—On the ground that the assimilable nutriment from a given weight of selected fruit and grain and nut and vegetable foods will cost less than the same nutriment obtained from flesh foods.

3. *Social Economy.*—On the ground that an acre of cultivable land under fruit and vegetable cultivation will produce from two to twenty times as much food as if the same land were utilized for feeding cattle.

4. *Racial Improvement.*—On the ground that the aim of every prosperous community should be to have a large proportion of hardy country yeomen, and that horticulture and agriculture demand such a high ratio of labour, as compared with feeding and breeding cattle, that the country population would be greatly increased by the substitution of a fruit and vegetable for an animal dietary.

5. *Character Improvement.*—On the ground that after the virtues of courage and valour and fearlessness have been taught in the lower stages of evolution, the virtue of gentle humaneness and extended sympathy for all that can suffer should be taught in the higher cycles of the evolutionary spiral. Flesh-eating entailing necessarily an immense volume of pain upon the sentient animal creation should be abstained from by the "higher classes" in the evolutionary scale.

Organizations have been established to advocate this method of living under the name of "Vegetarian Societies" in many countries—chiefly the United Kingdom, America, Germany, France, Austria, Holland and Australia. Propagandism is carried on by lectures, literature, cookery demonstrations and restaurants.

In England, the oldest and one of the most important societies is "The Vegetarian Society," of which the headquarters are at Oxford Street, Manchester. An attempt has been made to organize the various vegetarian societies of the world under the title of "The Vegetarian Federal Union." The headquarters of the London societies and of the "Union" are at Memorial Hall, Farringdon Street, E.C.

In the religious world the Seventh-Day Adventists (who are connected with many sanatoria and the manufacture of food specialties) and some Bible Christians, the worshippers of Vishnu and the Swami Narang and Vishnoi sects, amongst others, preach abstinence from flesh food. The Salvation Army, the Tolstoyans and the Doukhobors encourage it. A number of orders in the Roman Catholic church (*e.g.*, the Trappists) and in the Hindu faith (*e.g.*, the Dadupanthi Sadus) are pledged abstainers.

The general question of food values is discussed in the article DIETETICS; *see* also NUTRITION. But there is no doubt that, whatever may be the view taken as to the extreme theory of vegetarianism, it has had considerable effect in modifying the excessive meat-consuming régime of previous days, and in introducing new varieties of vegetable cooking into the service of the table.

BIBLIOGRAPHY.—The literature on the subject is considerable, but the two classics are perhaps *The Ethics of Diet*, by Howard Williams, and *The Perfect Way in Diet*, by Dr. Anna Kingsford. In former years the "Vegetarian Society" was the most active in producing literature, but since about 1901 the Order of the Golden Age has come to the front with new and up-to-date books, booklets and leaflets, and the Ideal Publishing Union has reprinted much of the earlier literature. The chief periodicals are the *Vegetarian* (weekly), the *Herald of the Golden Age* (monthly), the *Vegetarian Messenger* (monthly), the *Vegetarian* (American monthly), the *Children's Garden* (monthly). (J. O.)

VEGETIUS (FLAVIUS VEGETIUS RENATUS) (4th cent.), military writer. Nothing is known of his life save that in mss. he is called *vir illustris* and also *comes*. His treatise, ***Epitoma rei militaris, sive institutorum rei militaris libri quinque***, was dedicated to the reigning emperor (? Theodosius the Great). His sources, according to his own statement, were Cato, Cornelius Celsus, Frontinus, Paternus and the imperial constitutions of Augustus, Trajan and Hadrian. The book, a confused and unscientific compilation, has to be used with caution, but is important to the student of the ancient art of war.

In manuscript, Vegetius's work had a great vogue from the first, and its rules of siegecraft were much studied in the middle ages. It was translated into English, French and Bulgarian before the invention of printing. The first printed editions are assigned to Utrecht (1473), Cologne (1476), Paris (1478), Rome (in *Veteres de re mil. scriptores*, 1487), and Pisa (1488). A German translation by Ludwig Hohenwang appeared in 1475. The fullest modern edition is by Karl Lang (1869). An English version was published by Caxton in 1489. For a detailed critical estimate of Vegetius's works and influence *see* Max Jähns, *Gesch. der Kriegswissenschaften*, i. 109–125.

VEII, an ancient town of Etruria, Italy, situated about 10 m. N. by W. of Rome by road. It is mentioned in the earliest history of Rome as a constant enemy, being the nearest Etruscan city to Rome, but the site was occupied in the Villanova period, remains of huts having been found on the acropolis (called Piazza d'Armi) as well as numerous tombs. The story of the slaughter of the Fabii, who had encamped in the territory of Veii (perhaps in an effort to cut the communications of Veii with Fidenae) and of whom but one boy escaped, is well known. After constant warfare, the last war (the fourteenth, according to the annalists) broke out in 406 B.C. The Romans laid siege to the city, and, after a ten years' siege, M. Furius Camillus took it by storm in 396, by means, so we are told, of a tunnel leading into the citadel. According to the legend, the *emissarium* of the Alban Lake was constructed in obedience to the Delphic oracle, which declared that, until it was drained, Veii could not be taken. After the defeat of the Romans at the Allia in 390 B.C., a project was broached for abandoning Rome for Veii, which was successfully opposed by Camillus. Veii is spoken of by Propertius as almost deserted, but Augustus founded a municipality there, inscriptions of which have been found down to the time of Constantius.

Veii was reached by branch roads from the Via Clodia. The site is characteristic—a plateau, the highest point of which is 407 ft. above sea-level, divided from the surrounding country by deep ravines, and accessible only on the west, where it was defended by a wall and fosse. Remains of the city walls, built of blocks of tufa 2 ft. high, may be traced at various points in the circuit. The area covered measures about 1 sq.m. and it was thus only second to Rome in size among the cities in her neighbourhood. The site of the Forum has been discovered on the west side of the plateau; a statue of Tiberius, now in the Vatican, and the twelve Ionic columns now decorating the colonnade on the W. side of the Piazza Colonna at Rome were found there.

The acropolis was at the eastern extremity of the site, where the two ravines converge; it is connected with the rest of the plateau by a narrow neck. An Etruscan house was found on the north side of the city; while, just outside it on the south a temple of the 6th cent. B.C. with three cellae has been discovered. The most famous of the Etruscan tombs is the Grotta Campana, which contains paintings on the walls with representations of animals, among the earliest in Etruria. There are also several prominent tumuli. To a later period belongs a columbarium cut in the rock, with niches for urns. (T. A.)

VEINS, in anatomy. The veins are blood vessels which return the blood from the capillaries toward the heart. As they approach that organ they join together to form larger and larger trunks. In man and other mammals three venous systems are recognized: (1) the *general venous system;* (2) the *pulmonary system;* and (3) the *hepatic portal system.* (*See* also VASCULAR SYSTEM.)

General Venous System.—This consists of superficial and deep veins; the former lie in the superficial fascia and are often visible through the skin. They are usually accompanied by lymphatic vessels though not as a rule by arteries, and, sooner or later, they empty their blood into the deep veins, often passing through special openings in the deep fascia to do so. The deep veins always accompany arteries, and are therefore known as *venae comites.* With small and medium-sized arteries there are two of these venae comites, one on each side, connected by oc-

casional cross communications, but arteries of a larger calibre have only one companion vein. In the scalp and face the superficial veins accompany corresponding arteries more or less closely because the arteries in this region are very tortuous (*see* ARTERIES), while the veins run a comparatively straight course. *Frontal, superficial temporal, posterior auricular* and *occipital veins* are found in the scalp, their names indicating the areas they drain. Like all other superficial veins, they anastomose freely and also at certain places communicate, through foramina in the skull, with the intracranial blood sinuses; these communications are known as *emissary veins,* and act as safety-valves to the sinuses. The frontal vein on the forehead passes down on the inner side of the eyelids, where it is known as the *angular,* and then becomes the *facial vein,* which runs down to an inch in front of the angle of the jaw, whence it passes into the neck to join the common facial. In the greater part of its course it lies some distance behind the facial artery. The *superficial temporal vein* runs down in front of the ear, where it joins the internal maxillary vein from the pterygoid plexus and so forms the *temporo-maxillary trunk,* which passes down, embedded in the parotid gland, to about the angle of the jaw. Here it divides into an anterior branch, which joins the facial vein to form the common facial, and a posterior, which receives the posterior auricular vein, forming the external jugular.

The *external jugular vein* is easily recognized through the skin on the side of the neck, and eventually pierces the deep fascia above the middle of the clavicle to join the subclavian vein. The *occipital vein* sinks deeply into the back of the neck and so forms the beginning of the vertebral vein.

The *intracranial blood sinuses* lie between two layers of the dura mater and differ from the veins in having fibrous walls which do not contract or expand. The *superior longitudinal sinus* runs along the upper margin of the falx cerebri (*see* BRAIN), while the inferior longitudinal sinus runs along the lower margin; these drain the surface of the brain, and the blood passes backward in both. Where the falx meets the tentorium cerebelli, the inferior longitudinal sinus receives the *veins of Galen* from the interior of the brain and then passes backward as the *straight sinus* to join the superior longitudinal sinus at the internal occipital protuberance (*see* SKULL). This meeting-place is known as the *torcular Herophili,* and from it the blood passes outward and downward through the right and left *lateral sinuses,* which groove the cranium (*see* SKULL) until they reach the posterior lacerated foramina, through which they pass to form the beginning of the internal jugular veins. Most of the blood from the base of the brain passes into the *cavernous sinuses* which lie in the middle cranial fossa, one on each side of the pituitary fossa. These receive the ophthalmic veins from the orbit in front and, after running backward for about an inch, divide into the *superior* and *inferior petrosal sinuses,* the former of which joins the lateral sinus within the cranium, but the latter runs to the posterior lacerated foramen, after passing through which it joins the lateral sinus, which is now becoming the internal jugular vein. (*See* fig. 5.)

The *internal jugular vein* thus formed runs down at first behind and then to the outer side of the internal and common carotid arteries and at the root of the neck joins the subclavian vein of its own side to form the innominate vein. In its course down the neck it receives the common facial vein and tributaries from the tongue, pharynx, larynx and thyroid body. The deep veins of the head and face tend to form plexuses rather than venae comites; of these, *pterygoid, deep temporal, pharyngeal* and *suboccipital plexuses* are recognized.

Veins of the Upper Extremity.—On the dorsum of the hand and in front of the wrist superficial venous plexuses are easily seen through the skin. From these the blood passes up the forearm chiefly on its flexor surface by the *radial, median* and *anterior* and *posterior ulnar veins.* Just below the bend of the elbow the median vein communicates with the deep veins and then divides into two branches like the limbs of a **y**. Of these the inner is the *median basilic* from which patients are usually bled, while the outer is the *median cephalic.* After a course of an inch or two the median basilic is joined by the anterior and posterior ulnar veins and the median cephalic by the radial. After this junction the median basilic is continued up the inner side of the arm as the *basilic* which pierces the deep fascia about the middle of the arm and in the axilla joins the venae comites of the brachial artery to form the *axillary vein,* which lies on the inner side of its artery. The median cephalic vein after joining the radial runs up the outer side of the arm as the *cephalic* and a little below the clavicle passes through the costocoracoid membrane to enter the upper part of the axillary vein. At the outer border of the first rib the axillary vein becomes the subclavian, which lies in front of and below its artery and is separated from it by the scalenus anticus muscle. The arrangement of the superficial veins, especially in front of the elbow, is liable to great variation.

Veins of the Lower Extremity.—The superficial veins of the lower extremity begin in a venous arch on the dorsum of the foot. From the inner extremity of this the *internal saphenous vein* runs up, in front of the inner ankle, along the inner side of the leg, and, passing behind the inner side of the knee, continues up the thigh, gradually working forward until it reaches the *saphenous opening* in the deep fascia of the thigh a little below the spine of the pubis. Here it pierces the deep fascia (*fascia lata*) to enter the common femoral vein. In this long course it has many valves and receives numerous tributaries, one of which, the *saphenous collateral,* runs up nearly parallel to it and on its outer side and joins it just below the saphenous opening. From the inner end of the dorsal arch of the foot the *external saphenous vein* runs up behind the outer ankle along the mid line of the calf to pierce the deep fascia in the popliteal space behind the knee and open into the popliteal vein. Among the deep veins venae comites are found until the popliteal artery is reached, while above this *superficial, deep* and *common femoral veins* accompany their respective arteries. In the groin the common femoral vein lies on the inner side of its artery.

Veins of the Abdomen.—The common femoral vein, after passing deep to Poupart's ligament, becomes the *external iliac* which runs along the brim of the true pelvis and, after a course of some three inches, joins the *internal iliac* which drains the pelvis and so forms the *common iliac vein.* In front of the body of the fifth lumbar vertebra the common iliac veins of the two sides unite to form the *inferior vena cava,* a very large trunk which runs up on the right of the abdominal aorta to an opening in the diaphragm (*q.v.*). On its way it receives spermatic or ovarian veins from the genital glands, *renal veins* from the kidneys, and *lumbar veins* from the abdominal walls. Before reaching the diaphragm it lies in a groove in the back of the liver (*q.v.*) and receives the *hepatic veins* from that organ. The hepatic portal system which lies in the abdomen will be treated later.

Veins of the Thorax.—The inferior vena cava, after piercing the diaphragm, has a very short thoracic course and opens into the lower and back part of the right auricle of the heart (*q.v.*). The *right* and *left innominate veins* are formed behind the sternal end of the clavicle by the union of the subclavian and internal jugulars of their own side. The left vein is much longer than the right and runs nearly horizontally behind the upper half of the manubrium sterni to join its fellow on the right side of that bone just below the first rib. By the junction of these the *superior vena cava* is formed, which runs down to the right auricle of the heart. The chief tributaries of the innominate veins are the *vertebral,* the *internal mammary* and the *inferior thyroid.*

The intercostal veins open into the *azygos veins,* which begin in the abdomen sometimes by a vertical trunk joining the lumbar veins known as the *ascending lumbar,* sometimes on the right side by a communication with the inferior vena cava. The right azygos vein is known as the *vena azygos major* and passes through the aortic opening of the diaphragm. Entering the thorax, it runs up in front of the thoracic vertebrae, to the right of the aorta and thoracic duct, and receives the intercostal veins of the right side. At the level of the fourth thoracic vertebra it arches forward to open into the posterior surface of the superior vena cava.

On the left side, the upper intercostal veins join to form the left superior intercostal vein, which opens into the left innominate. Lower down the intercostal veins from the fourth to the seventh spaces form the *superior hemiazygos vein,* which runs down on

the left of the spinal column and, crossing it about the level of the eighth or ninth thoracic vertebra, opens into the vena azygos major. The lower intercostal veins on the left side join the *inferior hemiazygos vein* which runs up and opens either into the superior hemiazygos or into the azygos major below the opening of that vein.

Pulmonary Venous System.—The veins emerging from the lungs bring back the oxygenated blood from those organs to the left ventricle of the heart and also the greater part, if not all, of the blood carried by the bronchial arteries to nourish the lungs. The existence of bronchial veins is asserted, but they are extremely difficult to demonstrate, and if present are quite incapable of returning all the blood which the bronchial arteries carry to the lungs. There are three pulmonary veins coming out of the right lung, while on the left there are only two. On the right side, however, two of the three veins usually unite in the root of the lung, so that there are, as a rule, two pulmonary veins entering the left auricle of the heart on each side, but it is not uncommon to find three on the right side or one on the left. The pulmonary veins have no valves.

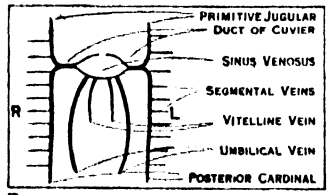
Hepatic Portal System.—The veins which drain the blood from the stomach, intestines, spleen and pancreas unite to form a large vein which begins behind the head of the pancreas and ends by dividing into right and left branches in the transverse fissure of the liver. This is the *portal vein* which lies in front of the inferior vena cava and is about three inches long. Its formative tributaries are the *superior* and *inferior mesenteric* and the *splenic veins*. There are two marked characteristics of the portal system; one is that it has no valves and the other that it begins and ends in capillaries, since the two terminal branches of the portal vein branch and rebranch in a manner already described in the article LIVER. In the lower part of the rectum the veins run partly into the portal and partly into the general system, and in this dependent position they are liable to become varicose and to form haemorrhoids or piles.

The histology of the veins corresponds very closely to that of the arteries (*q.v.*); their walls are, however, much thinner and there is less muscular and elastic tissue. At certain places, especially where tributaries come in, the endothelial lining is raised to form semilunar pocket-like valves. In most cases there are two cusps to each valve, but three or one are sometimes found. The opening of the pocket is arranged so that it shall only be filled when there is a tendency to regurgitation of the blood.

EMBRYOLOGY

The *vitelline* or *omphalo-mesenteric veins*, returning the blood from the yolk sac, are the first to appear, and later on, with the formation of the placenta, the umbilical veins develop. Both these open into the hinder (caudal) part of the heart, which is already being constricted off as the *sinus venosus* (*see* fig. 1).

While this is going on the veins from the different body segments are received into two longitudinal trunks on each side, the anterior (cephalic) of which is the *primitive jugular* or anterior cardinal and the posterior (caudal), the *posterior cardinal* or simply *cardinal vein*. As the heart is at first situated in the region which will later be the neck of the embryo, the primitive jugular receives very few segmental veins and the cardinal very many. These two trunks join one another on each side and open into the side of the *sinus venosus* by a transverse communication the *duct of Cuvier*. The condition of the venous system at this stage is shown in the accompanying diagram (fig. 1).



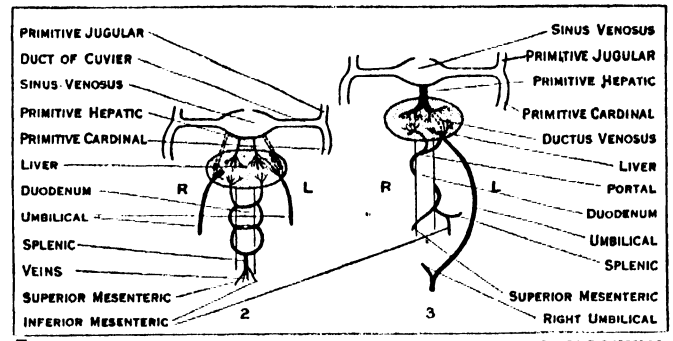


FIG. 1.—SCHEME OF FORMATION OF VENOUS SYSTEM, FIRST STAGE

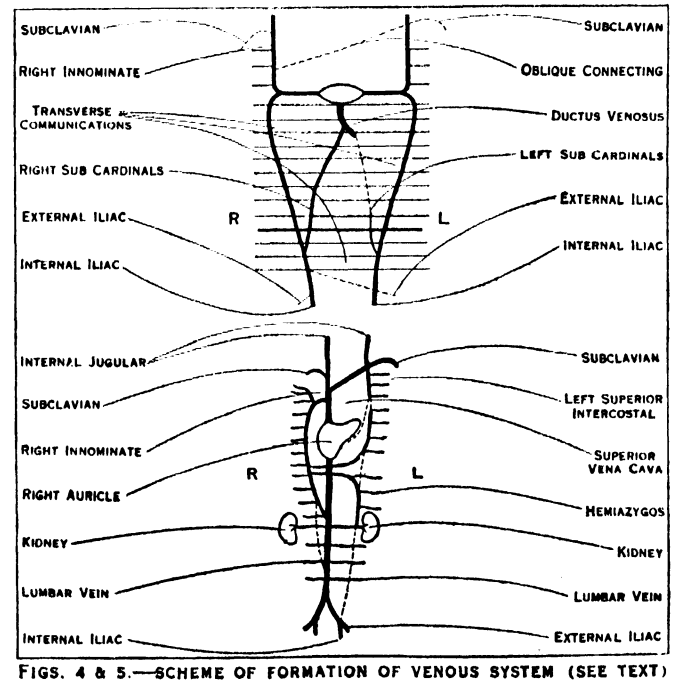

As the vitelline veins run from the yolk sac to the heart along each side of the primitive fore-gut they pick up the mesenteric veins from the intestines as well as the splenic and pancreatic veins as soon as these viscera are formed. The liver, however, is developed right across their path, and both they and the umbilical veins break up into a mass of capillaries in it, leaving that part of them which lies between the liver and the heart to form the primitive hepatic veins (fig. 2). While the vitelline veins are lying on each side of the fore-gut (future duodenum) they are connected by three transverse channels, the anterior and posterior of which appear on the ventral side of the gut, the middle on the dorsal side (*see* fig. 2). This figure of eight does not persist, however, because the anterior (cephalic) part of it on the left and the

FIGS. 2 & 3.—SCHEME OF FORMATION OF VENOUS SYSTEM, ABDOMINAL REGION

posterior (caudal) part on the right become obliterated, and what is left forms the *portal vein* (fig. 3). The two umbilical veins unite at the umbilicus (fig. 3) and soon all the blood from the placenta passes through the left one, the right becoming rudimentary.

The left umbilical vein on reaching the liver now joins the left branch of the portal vein and establishes a new communication with the left hepatic vein. This is the *ductus venosus* (fig. 3), and, as soon as it is formed, there is no longer any need that all the blood returning from the placenta should pass through the liver capillaries. The development of the cardinal veins must now be returned to. As the heart moves from the neck into the thorax the primitive jugulars elongate and it is now recognized become the internal jugulars in the greater part of their extent.

FIGS. 4 & 5.—SCHEME OF FORMATION OF VENOUS SYSTEM (SEE TEXT)

When the arms begin to bud out subclavian veins are developed (fig. 4) and an oblique connecting vein (figs. 4 and 5) is established between the point of junction of the left subclavian with the primitive jugular and the hinder part of the primitive jugular of the right side. This connection becomes the left innominate vein, while the hinder part of the primitive jugular persists as the *left superior intercostal vein* (fig. 5). On the right side that part of the primitive jugular between the subclavian and the junction with the left innominate becomes the right innominate (figs. 4 and 5) while the hinder (caudal) part of the right primitive jugular and

the right duct of Cuvier become the superior vena cava (figs. 4 and 5). The external jugular is a later formation. The right and left posterior cardinal veins receive the intercostal and lumbar segmental veins and are continued into the lower limbs as the internal iliac and eventually the sciatic veins, the primitive bloodpath from the thighs. The veins from the primitive kidneys open into the segmental veins, and when the permanent kidney is formed (*see* URINARY SYSTEM) a large *renal vein* on each side is established. There are, however, many cross communications (fig. 4) between the right and left posterior cardinal veins, some of which become very important later on, though most of them are transitory. The probable origin of the *inferior vena cava* is to be sought in a pair of veins called *subcardinals* which have been found in the rabbit embryo lying parallel and a little ventral to the posterior cardinals (fig. 4) and effecting a junction with the renals and transverse communications as they cross these. Posteriorly (caudal) they join the cardinals, but anteriorly the right one establishes a communication with the ductus venosus a little below the point at which that vessel joins the left hepatic. It is from the right one of these that the greater part of the inferior vena cava is formed. It will now be seen that the adult vena cava is formed by contributions from four embryonic veins, most anteriorly the hepatic, then the ductus venosus, then the right subcardinal and posteriorly the right posterior cardinal (F. T. Lewis, *Am. J. of Anat.* vol. 1., 229, 1902). The anterior (cephalic) part of the right posterior cardinal forms the *vena azygos major*, and an inspection of fig. 4 will show that in the adult this may rise from the renal, from an ascending lumbar vein or, by a cross communication above the renal, from the inferior vena cava. The left posterior cardinal becomes obliterated below and its segmental tributaries find their way by cross communications to the vena cava (fig. 5). Above (cephalad) the left renal vein the left cardinal forms the hemiazygos and, higher still, the hemiazygos accessoria. These open into the azygos major by persistent cross communications which lie dorsal to the heart when that organ reaches its permanent position. Some modern authorities doubt whether the azygos veins of mammals are really persistent cardinals except quite in their anterior parts, just before they join the ducts of Cuvier. The left duct of Cuvier is only represented in the human adult by the oblique vein of Marshall on the dorsum of the left auricle. The external iliac veins become fully developed, like their arteries, when the blood changes its course from the back to the front of the thigh. After birth the umbilical vein and the ductus venosus become converted into fibrous cords and the circulation in the pulmonary veins is established.

COMPARATIVE ANATOMY

In the Acrania (*Amphioxus*), although there is no heart, the blood vessels returning the blood to the subpharyngeal region are distinctly of a vertebrate type. There is a subintestinal vessel or vein bringing the blood from the intestine to the liver and breaking up into capillaries in that organ just as the portal vein does in the higher forms. From the liver a hepatic vein carries the blood forward to the region below the pharynx where the heart is formed in Vertebrata. There is no renal portal system. In the Cyclostomata (lampreys and hags) the cardinal veins are formed and the blood from the caudal vein passes directly into the posterior cardinals without any renal portal system. In fishes the single caudal vein divides into two branches, each of which runs forward to the outer side of its respective kidney and ends by giving numerous branches to that viscus. The blood returning from the kidney passes into the beginning of its own posterior cardinal vein or sinus, which lies on the inner side of the kidney. This constitutes a *renal portal system*. The cardinal veins and ducts of Cuvier closely resemble the arrangement already detailed in the human foetus, while the hepatic portal system from the intestine to the liver is constant in this and all other vertebrates.

In the Dipnoi (mud-fish) a pulmonary vein from the lung-like swim-bladder is formed and an inferior vena cava or postcaval vein carries the blood from the kidneys to the heart. This is its first appearance in the vertebrate phylum. In the lower fishes there is a vein of the lateral line on each side, but in the Dipnoi these coalesce and form a median anterior (ventral) abdominal vein which is constant in the Amphibia. Subclavian and iliac veins return the blood from the fins and open respectively into the junction of the anterior and posterior cardinals and into the caudal vein.

In the tailed Amphibia (*Urodela*) the postcaval and posterior cardinal veins are well developed, the former vessel running from the right cardinal vein a little in front of (cephalad) the kidney to the hepatic vein, in this way closely foreshadowing man's embryology. In the Anura (frogs and toads) the posterior cardinals are usually suppressed, but these are very specialized animals. The anterior abdominal vein in amphibians joins the portal vein close to the liver.

In the Reptilia the renal portal circulation persists, but is rudimentary in birds and disappears in mammals. The anterior abdominal or epigastric vein of amphibians and reptiles returns the blood from the allantois in the embryo and in higher forms becomes the umbilical vein returning the blood from the placenta; there is, therefore, a continuous line of ascent from the lateral line veins of the fish to the umbilical vein of man. In reptiles, birds, monotremes, marsupials and many rodents, insectivores, bats and ungulates, a left superior vena cava (precaval vein) is present as well as a right; it passes ventral to the root of the left lung and then dorsal to the left auricle of the heart until it reaches the coronary sinus to open into the right auricle. Its course is indicated in man by the left superior intercostal vein, the vestigial fold of Marshall (*see* COELOM AND SEROUS MEMBRANES) and the oblique vein of Marshall. It can be readily reconstructed from figs. 4 and 5 if the transverse communication (L.I.) is obliterated. In some mammals the postcaval vein is double, especially in its hinder (caudad) part, and this sometimes occurs as a human abnormality (*see* F. W. McClure, *Am. Journ. of Anat.* vol. 2, 1903, and vol. 5, 1906, also *Anat. Anzeiger*, Bd. 29, 1906).

Except in Cetacea, one or both azygos veins are always present in mammals. When there is only one it is usually the right, though a few forms among the marsupials, rodents and ungulates have only the left (F. E. Beddard, *P.Z.S.*, 1907, p. 181). In many of the lower mammals the external jugular vein is much larger than the internal and returns most of the blood from the brain through an opening called the postglenoid foramen. For this reason it was formerly regarded as the representative of the primitive jugular. It is now, however, thought that the internal jugular is that representative, and that the arrangement of man, in which the internal jugular drains the interior of the cranium, is the more generalized and primitive. (F. G. P.)

VEJER DE LA FRONTERA, a town of southern Spain, in the province of Cadiz, on the right bank of the river Barbate and on the Cadiz-Tarifa railway. Pop. (1920) 14,995. Vejer de la Frontera occupies a low hill overlooking the Straits of Gibraltar and surrounded by orchards and orange groves. The architecture of many of its houses recalls the period of Moorish rule, which lasted from 711 until the town was captured by St. Ferdinand of Castile in 1248.

VELA, one of the three southern constellations into which the large Ptolemaic constellation Argo (*q.v.*) was subdivided.

VELARIUM, the curtain or awning extended above the auditorium of the Roman theatres and amphitheatres to protect the spectators from sun and rain.

VELAZQUEZ, DIEGO RODRIGUEZ DE SILVA Y (1599–1660), the head of the Spanish school of painting and one of the greatest painters the world has known, was born in Seville and was baptized on June 6, 1599. His European fame is of comparatively recent origin, dating from the first quarter of the 19th century.

Early Life.—He was the son of Rodriguez de Silva, a lawyer in Seville, descended from a noble Portuguese family. Following a common Spanish usage, the artist is known by his mother's name Velazquez. He was known to his contemporaries as Diego de Silva Velazquez, and signed his name thus. He was intended for a learned profession, for which he received a good training in languages and philosophy. But the bent of the boy was towards art, and he was placed under the elder Herrera. Herrera was a bold and effective painter; but he was at the same time a man of unruly temper, and his pupils could seldom stay long with him. Velazquez soon left Herrera's studio and betook himself to the learned and pedantic Pacheco, in whose school he remained for five years, seeing all that was best in the literary and artistic circles of Seville. Here he fell in love with his master's daughter Juana de Miranda, whom he married on April 23, 1618. The young painter set himself to copy the commonest things about him—earthenware jars of the country people, birds, fish, fruit and flowers of the market-place. Carrying out this idea still further, Velazquez felt that to master the subtlety of the human face he must make this a special study, and he accordingly engaged a peasant lad to be his servant and model, making innumerable studies in charcoal and chalk, and catching his every expression. We see this model, probably, in the laughing boy of the Hermitage "Breakfast," or in the youngest of the "Musicians," acquired for the Berlin Museum in 1906. The position and fame of Velazquez were now assured at Seville. There his wife bore him two daughters—all his family so far as is known. The younger died in infancy, while the elder, Francisca, in due time married Bautista del Mazo, a painter, whose large family is that which is represented in the important picture in Vienna which was at one time called the "Family of Velazquez." This picture is now by common consent given to Mazo. Of his early Seville manner we have an excellent example in "El Aguador" (the Water-Carrier) at Apsley House (London). The brushwork is bold and broad, and the outlines firmly marked. As is usual with Velazquez at this time, the harmony of colours is red, brown and yellow, reminding one of Ribera. For sacred subjects we may turn to the "Adoration of the Magi" at Madrid, dated 1619, and the "Christ and the Pilgrims of Emmaus" in the Metropolitan Museum of Art, New York.

Life in Madrid.—But Velazquez was now eager to see more of the world. Madrid, with its fine Titians, held out strong inducements. Accordingly, in 1622, fortified with letters of introduction to Fonseca, who held a good position at court, he spent some months there. Here he painted the portrait of the poet Gongora, a commission from Pacheco (in the gallery at Madrid). In the following year he was summoned to return by Olivares, the all-powerful minister of Philip IV., fifty ducats being allowed to defray his expenses. On this occasion he was accompanied by his father-in-law. Next year (1624) he received from the king three hundred ducats to pay the cost of the removal of his family to Madrid, which became his home for the remainder of his life. King Philip remained for a period of thirty-six years the faithful and attached friend of Velazquez. By his equestrian portrait of the king, painted in 1623, Velazquez secured admission to the royal service with a salary of twenty ducats per month, besides medical attendance, lodgings and payment for the pictures he might paint. The portrait was exhibited on the steps of San Felipe, and was received with enthusiasm, being vaunted by poets, among them Pacheco. It has unfortunately disappeared. The Prado, however, has two portraits of the king in which the harshness of the Seville period has disappeared.

In 1628 Rubens visited Madrid on a diplomatic mission for nine months, and Velazquez was appointed by the king to be his guide among the art treasures of Spain. In 1627 the king had given for competition among the painters of Spain the subject of the Expulsion of the Moors. Velazquez bore off the palm for a picture no longer extant, and was appointed gentleman usher. To this was shortly afterwards added a daily allowance of twelve reals, and ninety ducats a year for dress. As an extra payment he received (though it was not paid for five years) one hundred ducats for the picture of Bacchus, painted in 1629 (Madrid gallery). The spirit and aim of this work are better understood from its Spanish name, "Los Borrachos" (the Topers), who are paying mock homage to a half-naked ivy-crowned young man seated on a wine barrel.

Visit to Italy.—In 1629 Philip gave Velazquez permission to visit Italy, without loss of salary, making him besides a present of four hundred ducats, to which Olivares added two hundred. He sailed from Barcelona in August in the company of the marquis de Spinola, the conqueror of Breda, then on his way to take command of the Spanish troops at Milan. It was during this voyage that Velazquez must have heard the details of the surrender of Breda from the lips of the victor, and he must have sketched his fine head, known to us also by the portrait by Van Dyck. But the great picture was not painted till later. In Venice Velazquez made copies of the "Crucifixion" and the "Last Supper" of Tintoretto, which he sent to the king, and in Rome he copied Michelangelo and Raphael, lodging in the Villa Medici till fever compelled him to remove into the city. Here he painted the "Forge of Vulcan" (Madrid gallery), in which Apollo narrates to the astonished Vulcan, a village blacksmith, the news of the loves of Venus, while four Cyclops listen to the scandal. The other work painted at the same time, "Joseph's Coat," now hangs in the Escorial. At Rome he also painted the two beautiful landscapes of the gardens of the Villa Medici, now in the Madrid museum, full of light, sparkle and charm. After a visit to Naples in 1631, where he worked with his countryman Ribera, and painted a charming portrait of the Infanta Maria Queen of Hungary and sister of Philip, Velazquez returned to Madrid.

Court Painter.—He then painted the first of many portraits of the young prince, Don Baltasar Carlos, the heir to the throne, dignified and lordly even in his childhood, caracoling in the dress of a field-marshal on his prancing steed. The Duke of Olivares, the king's powerful minister, was the early and constant patron of the painter. His impassive, saturnine face is familiar to us from the many portraits painted by Velazquez. Two are of surpassing excellence—the full-length in the collection of the Hispanic Society, New York, stately and dignified, in which he wears the green cross of Alcantara; the other the great equestrian portrait of the Madrid gallery. In these portraits Velazquez has well repaid the debt of gratitude which he owed to his first patron, whom he stood by in his fall, thus exposing himself to the risk of incurring the anger of the jealous Philip. The king, however, showed no sign of malice towards his favoured painter, whom he visited daily in his studio in the palace, and to whom he sat in many attitudes and costumes, as a huntsman with his dogs, as a warrior in command of his troops. His pale face and lack-lustre eye, his fair flowing hair and moustaches curled up to his eyes, and his heavy projecting Hapsburg under-lip are known in many a portrait and nowhere more supremely than in the wonderful canvas of the London National Gallery where he seems to live and breathe. Here the consummate handling of Velazquez is seen at its best, for it is in his late and most perfect manner. From one of the equestrian portraits of the king, painted in 1638, the sculptor Montañes modelled a statue which was cast in bronze by the Florentine sculptor Tacca, and which now stands in the Plaza del Oriente at Madrid. This portrait exists no more; but there is no lack of others, for Velazquez was in constant attendance on Philip, accompanying him in his journeys to Aragon in 1642 and 1644, and was doubtless present with him when he entered Lerida as a conqueror. It was then that he painted the great equestrian portrait (Madrid gallery) in which the king is represented as a great commander leading his troops. It hangs as a pendant to the great Olivares portrait—fit rivals of the neighbouring Charles V. by Titian. At Fraga in Aragon in 1644 he painted a portrait of the king in country costume the original of which seems to be in the Frick collection, New York, while the Dulwich Gallery has a copy.

But, besides the portraits of the king, we have portraits of other

members of the royal family, of Philip's first wife, Isabella of Bourbon, and her children, especially of her eldest son, Don Baltasar Carlos, of whom, besides the equestrian portrait already mentioned, there is a full-length at the Vienna Museum, one in hunting dress at the Prado, and one at the Boston Museum with a dwarf. The Admiral Pulido Pareja at the National Gallery, is said to have been taken by Philip for the living man; nevertheless, A. de Beruete is emphatic in denying Velazquez's authorship of this picture, which he attributes to Mazo. The Duke of Modena on a visit to Madrid was painted by the artist (Modena Gallery) and of the same period are two male portraits at Dresden "The Count of Benevent," "The Sculptor Martinez Montañez" in the Madrid gallery, and "The Unknown Man" at Aspley House. One wonders who "the lady with the fan" can be that adorns the Wallace collection, the splendid brunette so unlike the usual fair-haired female sitters to Velazquez. She belongs to this period of his work, to the ripeness of his middle period. The touch is firm but free, showing the easy strength of the great master. But, if we have few ladies of the court of Philip, we have in great plenty his buffoons and dwarfs. Even these deformed or half-witted creatures attract our sympathy as we look at their portraits by Velazquez, who, true to his nature, treats them gently and kindly, as in "El Primo" (the Favourite), whose intelligent face and huge folio with ink-bottle and pen by his side show him to be a wiser and better-educated man than many of the gallants of the court. We now turn to one of the greatest of historical works, the "Surrender of Breda," often known as "Las Lanzas," from the serried rank of lances breaking the sky, which is believed to have been painted between 1638 and 1644. It represents the moment when the vanquished Justin of Nassau in front of his Dutch troops is submissively bending as he offers to his conqueror Spinola the keys of the town, which, with courteous grace, the victor refuses to accept.

The greatest of the religious paintings by Velazquez belongs also to this middle period, the "Christ on the Cross" (Madrid gallery). Palomino says it was painted in 1638 for the convent of San Placido. The Saviour's head hangs on his breast and a mass of dark tangled hair conceals part of the face. The beautiful form is projected against a black and hopeless sky. The figure stands absolutely alone, without any accessory. To the same period belongs the great "Boar Hunt" at the National Gallery, a magnificent work in spite of some restorations.

Second Visit to Italy.—Velazquez's son-in-law Mazo had succeeded him as usher in 1634, and he himself had received steady promotion in the royal household, receiving a pension of 500 ducats in 1640, increased to 700 in 1648, for portraits painted and to be painted, and being appointed inspector of works in the palace in 1647. Philip now entrusted him with the founding of an academy of art in Spain. Rich in pictures, Spain was weak in statuary, and Velazquez was commissioned to proceed to Italy to make purchases. Accompanied by his faithful slave Pareja, whom he taught to be a good painter, he sailed from Malaga in 1649, landing at Genoa, and proceeding thence by Milan to Venice, buying Titians, Tintorettos and Veroneses. A noble example of the painter's third manner is the great portrait of Innocent X. in the Doria palace at Rome, where he was received with marked favour by the pope, who presented him with a medal and gold chain. Of this portrait, thought by Sir Joshua Reynolds to be the finest picture in Rome, Palomino says that Velazquez took a copy to Spain. There exist several in different galleries. The handling is rapid but unerring. Velazquez had now reached the *manera abreviada*, as the Spaniards call this bolder style. His early and laborious studies and his close observation of nature had given to him in due time, as to all great painters, the power of representing what he saw by simpler means. At Rome he painted also a portrait of his servant Pareja, probably the picture of Lord Radnor's collection which procured his election into the academy of St. Luke. Meanwhile Philip was wearying for his return; accordingly Velazquez embarked in Genoa for Barcelona in 1651, taking with him many pictures and 300 pieces of statuary, which he afterwards arranged and catalogued for the king.

Late Life.—Isabella of Bourbon had died in 1644, and the king had married Mariana of Austria, whom Velazquez now painted in many attitudes. He was specially chosen by the king to fill the high office of "aposentador major," which imposed on him the duty of looking after the quarters occupied by the court whether at home or in their journeys. His works of this period are amongst the highest examples of his style. The dwarfs "El Bobo de Coria," "El Niño de Vallecas" and "Don Antonio el Inglés" (the Englishman) with his dog, "Aesop," and "Menippus," all in the Madrid gallery, show his surest and freest manner. To these may be added the charming children's portraits of the Infanta Margarita in Vienna, among the choicest of his works. It is Margarita, the eldest daughter of the new queen, that is the subject of the well-known picture "Las Meniñas" (the Maids of Honour), in the Madrid gallery, painted in 1656, where the little lady holds court, surrounded by her ladies-in-waiting, her dwarfs and her mastiff, while Velazquez is seen standing at his easel. This is the finest portrait we have of the great painter. It is a face of much dignity, power and sweetness—like his life. The story is told that the king painted the red cross of Santiago on the breast of the painter, as it appears to-day on the canvas. Velazquez did not, however, receive the honour till 1659, three years after the execution of this work. Even the powerful king of Spain could not make his favourite a belted knight without a commission to inquire into the purity of his lineage on both sides of the house. The records of this commission have been found among the archives of the order of Santiago by M. Villaamil. Fortunately the pedigree could bear scrutiny, as for generations the family was found free from all taint of heresy, from all trace of Jewish or Moorish blood and from contamination by trade or commerce. The difficulty connected with the fact that he was a painter was got over by his being painter to the king and by the declaration that he did not sell his pictures. But for this royal appointment, which enabled him to escape the censorship of the Inquisition, we should never have had his splendid "Venus and Cupid," bought by the National Art Collections Fund for £45,000 for the National Gallery in 1905. On occasions Philip gave commissions for religious pictures to Velazquez—among others, the "Coronation of the Virgin" (Madrid gallery), splendid in colour—a harmony of red, blue and grey. It was painted for the oratory of the queen, in the palace at Madrid. Another royal commission for the hermitage of Buen Retiro was the "St. Anthony the Abbot and St. Paul the Hermit," painted in 1659 (Madrid gallery). The last of his works which we shall name is "Las Hilanderas" or the Spinners (Madrid), painted about 1656, representing the royal tapestry works.

In 1660 a treaty of peace between France and Spain was to be consummated by the marriage of the infanta Maria Theresa with Louis XIV., and the ceremony was to take place in the Island of Pheasants, in the Bidassoa. Velazquez was charged with the decoration of the Spanish pavilion and with the whole scenic display. In the midst of the grandees of the first two courts in Christendom Velazquez attracted much attention by the nobility of his bearing and the splendour of his costume. On June 26 he returned to Madrid, and on July 31 he was stricken with fever. Feeling his end approaching, he signed his will, appointing as his sole executors his wife and his firm friend Fuensalida, keeper of the royal records. He died on Aug. 6, 1660. He was buried in the Fuensalida vault of the church of San Juan, and within eight days his wife Juana was laid beside him. This church was destroyed by the French in 1811, so that his place of interment is now unknown.

Velazquez can hardly be said to have formed a school of painting. Yet his influence on those immediately connected with him was considerable. In 1642 he befriended young Murillo on his arrival in Madrid, received him into his house, and directed his studies for three years. He helped to lay the foundations of modern painting; and when centuries later the Impressionists made it their aim to study the effect of light and atmosphere Velazquez was hailed as their precursor.

VELEIA, an ancient town of Aemilia, Italy, situated about 20 m. S. of Placentia, mentioned by Pliny. Its inhabitants were in the census of Vespasian found to be remarkable for their longevity. Nothing further was known of it until 1747, when some ploughmen found the famous *Tabula alimentaria*. This, the largest inscribed bronze tablet of antiquity (4 ft. 6 in. by 9 ft. 6 in.) contains the list of estates in the territories of Veleia, Libarna, Placentia, Parma and Luca, in which Trajan had assigned (before A.D. 102), 72,000 sesterces (£720) and then 1,044,000 sesterces (£10,440), on a mortgage bond to forty-six estates, the total value of which was reckoned at over 13,000,000 sesterces (£130,000), the interest on which at 5% was to serve for the support of 266 boys and 36 girls, the former receiving 16, the latter 12 sesterces a month. Excavations were begun in 1760, and the forum and basilica, the thermae and the amphitheatre, private houses, etc., with many statues and inscriptions (from 49 B.C. to A.D. 276) were discovered. Most of the objects found are in the museum at Parma. Oil has been extracted in the neighbourhood since 1890.

See G. Antolini, *Le Rovine di Veleia* (Milan, 1831).

VELEZ DE GUEVARA, LUIS (1579–1644), Spanish dramatist and novelist, was the author of over 400 plays, of which the best known are *Reinar despues de morir* and *Más pesa el rey que la sangre*. He won considerable fame as the author of *El Diablo cojuelo* (1641), a fantastic novel which suggested to Le Sage the idea of his *Diable boiteux*.

VELEZ-MALAGA, a town of southern Spain, in the province of Malaga, finely situated in a fertile valley at the southern base of the lofty Sierra de Alhama, and on the left bank of the small river Velez, 1 m. from its mouth and 27 m. by road E.N.E. of Malaga. Pop. (1920), 24,893. Velez-Malaga was taken from the Moors in 1487 by Ferdinand of Castile. Under Moorish rule the citadel was built and the town became an important trading station and fortress.

VELIA, an ancient town of Lucania (Gr. Ὑέλη, later Ἐλέα), Italy, on the hill now crowned by the mediaeval castle of Castellammare della Bruca, 440 ft. above sea-level, on the south-west coast, 1¾ m. N.W. of the modern railway station of Ascéa, 25 m. S.E. of Paestum. Remains of the city walls, with traces of one gate and several towers, of a total length of over 3 m., still exist. It is celebrated for the philosophers who bore its name. (*See* ELEATIC SCHOOL.) About 530 B.C. the Phocaeans, driven from Corsica, seized it from the Oenotrians. Its coins were widely diffused in S. Italy, and it kept its independence till 78 B.C.

VELIKA KIKINDA, a town in the Voivodina, Yugoslavia, Pop. (1921) 25,809; about 60% being Serbs. It is one of the centres of production of the famous wheat of the Banat.

VELLEIUS PATERCULUS, MARCUS (*c.* 19 B.C.–*c.* A.D. 31), Roman historian. Although his praenomen is given as Marcus by Priscian, some modern scholars identify him with Gaius Velleius Paterculus, whose name occurs in an inscription on a north African milestone (*C.I.L.* viii. 10, 311). He belonged to a distinguished Campanian family, and early entered the army. He served as military tribune in Thrace, Macedonia, Greece and the East, and in A.D. 2 was present at the interview on the Euphrates between Gaius Caesar, grandson of Augustus, and the Parthian king. Afterwards, as praefect of cavalry and legatus, he served for eight years (from A.D. 4) in Germany and Pannonia under Tiberius. He was quaestor in A.D. 7, praetor in 15, and was still alive in 30. He may have been put to death in 31 as a friend of Seianus. He wrote a compendium of Roman history from the dispersion of the Greeks after the siege of Troy down to the death of Livia (A.D. 29). The period from the death of Caesar to that of Augustus is treated most fully, and the disproportion is accentuated by the loss of a great deal of the early history. Most of the work is professedly a compendium; where he allows himself scope his style shows distinct traces of the Silver Age: antithesis, epigram, the breakdown of the periodic sentence.

Editio princeps, Basle, 1520; early editions by Justus Lipsius, J. Gruter, N. Heinsius, P. Burmann; modern editions, Ruhnken and Frotscher (1830–39), J. C. Orelli (1835), F. Kritz (1840, ed. min. 1848), F. Haase (1858), C. Halm (1876), R. Ellis (1898). Eng. trans. by J. S. Watson in Bohn's Classical Library. *See* also J. Wight Duff, *Literary History of Rome in the Silver Age* (1927).

VELLETRI (anc. *Velitrae*), a town and episcopal see of the province of Rome, Italy, at the south-east foot of the outer ring wall of the Alban crater, 26 m. S.E. of Rome by rail and 24 by electric tramway, 1,155 ft. above sea-level. Pop. (1921) 19,660 (town), 25,781 (commune). It is the seat of the bishop of Ostia. Good wine is made in the vineyards and there is a government experimental station for viticulture. Velletri is the junction of the Terracina line and a branch to Segni, on the main line to Naples. At the highest point is the municipal palace. The internal façade of the Palazzo Ginetti is finely decorated with stucco, and has a curious detached baroque staircase by Martino Lunghi the younger. The lofty campanile of S. Maria del Trivio, erected in 1353, is in the style of contemporary brick campanili in Rome, but built mainly of black selce (lava), with white marble columns at the windows. The cathedral, reconstructed in 1660, contains traces of the 13th century structure.

The ancient city of Velitrae was Volscian in Republican times, and it is the only Volscian town of which an inscription in that language is preserved (4th century B.C.). It mentions the two principal magistrates as *medix*. Velitrae was important as commanding the approach to the valley between the Alban and Volscian mountains. Interesting terra cotta reliefs from a Volscian temple have been found (esp. 5th cent. B.C.) belonging to the period when it had regained its freedom after its first capture by Rome. It was only reduced in 338 and was punished by the destruction of its walls and the banishment of its town councillors to Etruria, while their lands were handed over to Roman colonists. It was the home of the *gens Octavia*, to which the Emperor Augustus belonged. (T. A.)

VELLORE, a town of British India, headquarters of the North Arcot district of Madras, on the river Palar and 5 m. from a station on the South Indian railway, 87 m. W. of Madras city. Pop. (1921) 50,210. It has a strongly built fortress, which was famous in the wars of the Carnatic. Dating traditionally from the 13th century, but more probably only from the 17th, it is a fine example of Indian military architecture, and contains a finely sculptured temple. In 1780 it withstood a siege for two years by Hyder Ali. After the fall of Seringapatam (1799) Vellore was selected as the residence of the sons of Tippoo Sahib, and to them have been attributed the mutiny of the sepoys here in 1806.

VELLUM: *see* PARCHMENT.

VELOCITY OF LIGHT. The fact that light is propagated with a definite speed was first brought out by Ole Roemer at Paris, in 1676, through observations of the eclipses of Jupiter's satellites made in different relative positions of the Earth and Jupiter in their respective orbits. It is possible in this way to determine the time required for light to pass across the orbit of the earth. The dimensions of this orbit, or the distance of the sun, being taken as known, the actual speed of light could be computed. (*See* also PARALLAX.) Since this computation requires a knowledge of the sun's distance, which has not yet been acquired with certainty, the actual speed is now determined by experiments made on the earth's surface. Were it possible by any system of signals to compare with absolute precision the times at two different stations, the speed could be determined by finding how long was required for light to pass from one station to another at the greatest visible distance. But this is impracticable, because no natural agent is under our control by which a signal could be communicated with a greater velocity than that of light. It is therefore necessary to reflect a ray back to the point of observation and to determine the time which the light requires to go and come. Two systems have been devised for this purpose. One is that of Fizeau, in which the vital appliance is a rapidly revolving toothed wheel; the other is that of Foucault, in which the corresponding appliance is a mirror revolving on an axis in its own plane.

Fizeau, 1849.—The principle underlying Fizeau's method is

shown in the accompanying figs. 1 and 2. Fig. 1 shows the course of a ray of light which, emanating from a luminous point L, strikes the plane surface of a plate of glass M at an angle of about 45°. A fraction of the light is reflected from the two surfaces of the glass to a distant reflector R, the plane of which is at right angles to the course of the ray. The latter is thus reflected back on its own course and, passing through the glass M on its return, reaches

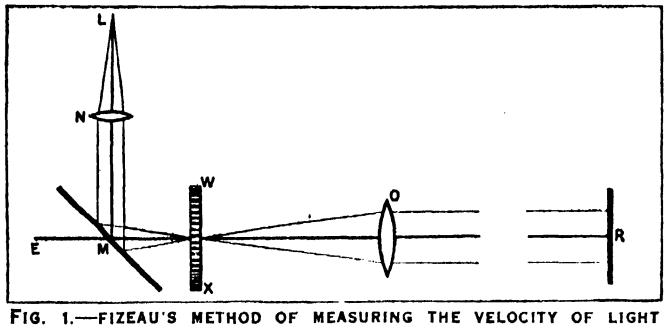

FIG. 1.—FIZEAU'S METHOD OF MEASURING THE VELOCITY OF LIGHT BY MEANS OF A TOOTHED WHEEL

a point E behind the glass. An observer with his eye at E looking through the glass sees the return ray as a distant luminous point in the reflector R, after the light has passed over the course in both directions.

In actual practice it is necessary to interpose the object glass of a telescope at a point O, at a distance from M nearly equal to its focal length. The function of this appliance is to render the diverging rays, shown by the dotted lines, nearly parallel, in order that more light may reach R and be thrown back again.

Conceiving the apparatus arranged in such a way that the observer sees the light reflected from the distant mirror R, a fine toothed wheel WX is placed immediately in front of the glass M, with its plane perpendicular to the course of the ray, in such a way that the ray goes out and returns through an opening between two adjacent teeth. This wheel is represented in section by WX in fig. 1, and a part of its circumference, with the teeth as viewed by the observer, is shown in fig. 2. We conceive that the observer sees the luminous point between two of the teeth at K. Now, conceive that the wheel is set in revolution. The ray is then interrupted as every tooth passes, so that what is sent out is a succession of flashes. Conceive that the speed of the wheel is such that while the flash is going to the distant mirror and returning again, each tooth of the wheel takes the place of an opening between the teeth. Then each flash sent out will, on its return, be intercepted by the adjacent tooth, and will therefore become invisible. If the speed be now doubled, so that the teeth pass at intervals equal to the time required for the light to go and come, each flash sent through an opening will return through the adjacent opening, and will therefore be seen with full brightness. If the speed be continuously increased the result will be successive disappearances and reappearances of the light, according as a tooth is or is not interposed when the ray reaches the apparatus on its return. The computation of the time of passage and return is then very simple. The speed of the wheel being known, the number of teeth passing in one second can be computed.

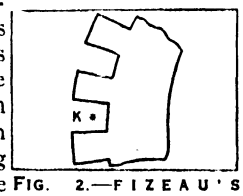

FIG. 2.—FIZEAU'S METHOD OF MEASURING THE VELOCITY OF LIGHT

Foucault, 1862.—The Foucault system is much more precise, because it rests upon the measurement of an angle, which can be made with great precision.

The vital appliance is a rapidly revolving mirror. Let AB (fig. 3) be a section of this mirror, which we shall first suppose at rest. A ray of light LM emanating from a source at L, is reflected in the direction MQR to a distant mirror R, from which it is perpendicularly reflected back upon its original course. This mirror R should be slightly concave, with the centre of curvature near M, so that the ray shall always be reflected back to M on whatever point of R it may fall. Conceiving the revolving mirror M as at rest, the return ray will after three reflections, at M, R and M again, be returned along its original course to the point L from which it emanated. An important point is that the return ray will always follow the fixed line ML no matter what the position of the movable mirror M, provided there is a distant reflector to send the ray back. Now, suppose that, while the ray is going and coming, the mirror M, being set in revolution, has turned from the position in which the ray was reflected to that shown by the dotted line. If α be the angle through which the surface has turned, the course of the return ray, after reflection, will then deviate from ML by the angle 2α, and so be thrown to a point E, such that the angle $LME = 2\alpha$. If the mirror is in rapid rotation the ray reflected from it will strike the distant mirror as a series of flashes, each formed by the light reflected when the mirror was in the position AB. If the speed of rotation is uniform, the reflected rays from the successive flashes while the mirror is in the dotted position will thus all follow the same direction ME after their second reflection from the mirror. If the motion is sufficiently rapid an eye observing the reflected ray will see the flashes as an invariable point of light so long as the speed of revolution remains constant. The time required for the light to go and come is then equal to that required by the mirror to turn through half the angle LME, which is therefore to be measured In practice it is necessary on this system, as well as on that of Fizeau, to condense the light by means of a lens, Q, so placed that L and R shall be at conjugate foci. The position of the lens may be either between the luminous point L and the mirror M, or between M and R, the latter being the only one shown in the figure. A difficulty associated with the Foucault system in the form in which its originator used it is that if the axis of the mirror is at right angles to the course of the ray, the light from the source L will be flashed directly into the eye of the observer, on every passage of the revolving mirror through the position in which its normal bisects the two courses of the ray. This may be avoided by inclining the axis of the mirror.

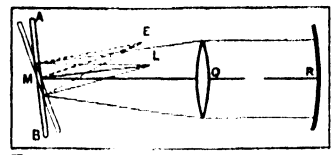

FIG. 3.—PRINCIPLE OF FOUCAULT'S METHOD OF DETERMINING THE VELOCITY OF LIGHT

In Foucault's determination the measures were not made upon a luminous point, but upon a reticule, the image of which could not be seen unless the reflector was quite near the revolving mirror. Indeed the whole apparatus was contained in his laboratory. The effective distance was increased by using several reflectors; but the entire course of the ray measured only 20 metres. The result reached by Foucault was 298,000 kilometres per second.

Cornu, 1874.—The most elaborate determination yet made by Fizeau's method was that of Cornu. The station of observation was at the Paris Observatory. The distant reflector, a telescope with a reflector at its focus, was at Montlhéry, distant 22,910 metres from the toothed wheel. Of the wheels most used one had 150 teeth, and was 35 millimetres in diameter; the other had 200 teeth, with a diameter of 45 mm. The highest speed attained was about 900 revolutions per second. At this speed, 135,000 (or 180,000) teeth would pass per second, and about 20 (or 28) would pass while the light was going and coming. But the actual speed attained was generally less than this. The definitive result derived by Cornu from the entire series of experiments was 300,400 km. per second. Further details of this work need not be set forth because the method is in several ways deficient in precision. The eclipses and subsequent reappearances of the light taking place gradually, it is impossible to fix with entire precision upon the moment of complete eclipse. The outcome of the inherent difficulties of the method is that, although Cornu's discussion of his experiments is a model in the care taken to determine so far as practicable every source of error, his definitive result is shown by other determinations to have been too great by about $\frac{1}{1000}$ part of its whole amount.

Michelson, 1878–79–82, and Newcomb, 1881–82.—The first marked advance on Foucault's determination was made by Albert A. Michelson, then a young officer on duty at the U.S. Naval academy, Annapolis. The improvement consisted in using the image of a slit through which the rays of the sun passed after reflection from a heliostat. In this way it was found possible to

see the image of the slit reflected from the distant mirror when the latter was nearly 600 metres from the station of observation. The essentials of the arrangement are those we have used in fig. 3, L being the slit. It will be seen that the revolving mirror is here interposed between the lens and its focus. It was driven by an air turbine, the blast of which was under the control of the observer, so that it could be kept at any required speed. The speed was determined by the vibrations of two tuning forks. One of these was an electric fork, making about 120 vibrations per second, with which the mirror was kept in unison by a system of rays reflected from it and the fork. The speed of this fork was determined by comparison with a freely vibrating fork from time to time. The speed of the revolving mirror was generally about 275 turns per second, and the deflection of the image of the slit about 112·5 mm. The mean result of nearly 100 fairly accordant determinations was:

Velocity of light in air	299,828 km. per sec.
Reduction to a vacuum	+82
Velocity of light in a vacuum	299,910±50.

Simon Newcomb about this time obtained the official support necessary to make a determination on a yet larger scale. The most important modifications made in the Foucault-Michelson system were the following:

1. Placing the reflector at a distance of several kilometres.

2. In order that the disturbances of the return image due to the passage of the ray through more than 7 km. of air might be reduced to a minimum, an ordinary telescope of the "broken back" form was used to send the ray to the revolving mirror.

3. The speed of the mirror was, as in Michelson's experiments, completely under control of the observer, so that by drawing one or the other of two cords held in the hand the return image could be kept in any required position. In making each measure the receiving telescope hereafter described was placed in a fixed position and during the "run" the image was kept as nearly as practicable upon a vertical thread passing through its focus. A "run" generally lasted about two minutes, during which time the mirror commonly made between 25,000 and 30,000 revolutions. The speed per second was found by dividing the entire number of revolutions by the number of seconds in the "run." The extreme deviations between the times of transmission of the light, as derived from any two runs, never approached to the thousandth part of its entire amount. The average deviation from the mean was indeed less than $\frac{1}{5000}$ part of the whole.

To avoid the injurious effect of the directly reflected flash, as well as to render unnecessary a comparison between the directions of the outgoing and the return ray, a second telescope, turning horizontally on an axis coincident with that of the revolving mirror, was used to receive the return ray after reflection. This required the use of an elongated mirror of which the upper half of the surface reflected the outgoing ray, and the lower other half received and reflected the ray on its return. On this system it was not necessary to incline the mirror in order to avoid the direct reflection of the return ray. The greatest advantage of this system was that the revolving mirror could be turned in either direction without break of continuity, so that the angular measures were made between the directions of the return ray after reflection when the mirror moved in opposite directions. In this way the speed of the mirror was as good as doubled, and the possible constant errors inherent in the reference to a fixed direction for the sending telescope were eliminated. The essentials of the apparatus are shown in fig. 4. The revolving mirror was a rectangular prism M of steel, 3 in. high and 1½ in. on a side in cross section, which was driven by a blast of air acting on two fan-wheels, not shown in the fig., one at the top, the other at the bottom of the mirror. NPO is the object-end of the fixed sending telescope the rays passing through it being reflected to the mirror by a prism P. The receiving telescope ABO is straight, and has its objective under O. It was attached to a frame which could turn around the same axis as the mirror. The angle through which it moved was measured by a divided arc immediately below its eye-piece, which is not shown in the figure. The position AB is that for receiving the ray during an anti-clockwise rotation of the mirror; the position A'B' that for a clockwise rotation.

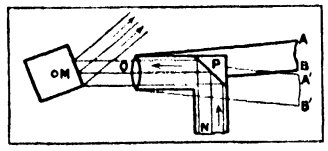

FIG. 4.—MICHELSON'S EARLIER APPARATUS FOR DETERMINING THE VELOCITY OF LIGHT

In these measures the observing station was at Fort Myer, on a hill above the west bank of the Potomac river. The distant reflector was first placed in the grounds of the Naval observatory, at a distance of 2,551 metres. But the definitive measures were made with the reflector at the base of the Washington monument, 3,721 metres distant. The revolving mirror was of nickel-plated steel, polished on all four vertical sides. Thus four reflections of the ray were received during each turn of the mirror, which would be coincident were the form of the mirror invariable. During the preliminary series of measures it was found that two images of the return ray were sometimes formed, which would result in two different conclusions as to the velocity of light, according as one or the other was observed. The only explanation of this defect which presented itself was a tortional vibration of the revolving mirror, coinciding in period with that of revolution.

In the summer of 1881 the distant reflector was removed from the Observatory to the Monument station. Six measures made in August and September showed a systematic deviation of +67 km. per second from the result of the Observatory series. This difference led to measures for eliminating the defect from which it was supposed to arise. The pivots of the mirror were reground, and a change made in the arrangement, which would permit of the effect of the vibration being determined and eliminated. This consisted in making the relative position of the sending and receiving telescopes interchangeable. In this way, if the measured deflection was too great in one position of the telescopes, it would be too small by an equal amount in the reverse position. As a matter of fact, when the definitive measures were made, it was found that with the improved pivots the mean result was the same in the two positions. But the new result differed systematically from both the former ones. Thirteen measures were made from the Monument in the summer of 1882. The mean results for the three series were:

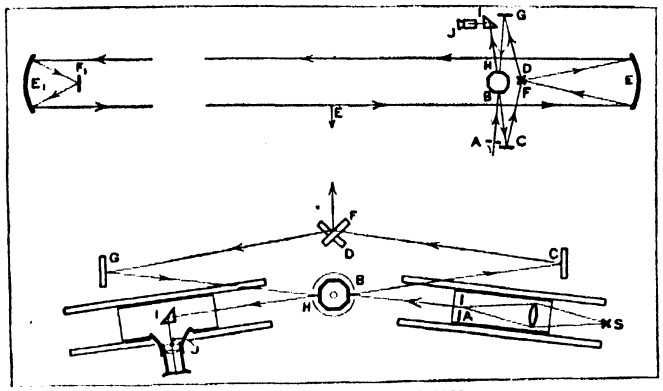
Observatory, 1880–1	V in air = 299,627
Monument, 1881	V in air = 299,694
Monument, 1882	V in air = 299,778

The last result being the only one from which the effect of distortion was completely eliminated, has been adopted as definitive. For reduction to a vacuum it requires a correction of +82 km. Thus the final result was concluded to be

Velocity of light in vacuo = 299,860 km. per second.

This result being less by 50 km. than that of Michelson, the latter made another determination with improved apparatus and arrangements at the Case School of Applied Science in Cleveland. The result was

Velocity in vacuo = 299,853 km. per second.



So far as could be determined from the discordance of the separate measures, the mean error of Newcomb's result would be less than ±10 km. But making allowance for the various sources of systematic error the actual probable error was estimated at ±30 km.

The angle α in Foucault's experiments cannot be measured with the required accuracy by any of the preceding methods, but, as was pointed out by Newcomb, this difficulty is avoided by giving the revolving mirror a prismatic form, and making the distance between the two stations so great that the return light is reflected at the same angle by the next following face of the prism.

Michelson, 1924–26, arranged for an attempt to realise such a project between stations on Mt. Wilson and Mt. San Antonio, near Pasadena, about 22 m. apart. For this distance, given a speed of rotation of 1,060 turns per second, the angular displacement of the mirror, during the double journey, will be 90°, or, if the speed were half as great, an angle of 45° would suffice. Accordingly, the revolving mirror may have the form of an octagon. It is, of course, very important that the angles of the octagon

should be equal, at least to the order of accuracy desired. It has been found possible, by special methods, to produce an octagon on which the average error is of the order of one-millionth, that is, about one-tenth to one-twentieth of a second.

Difficulties arise from the direct reflection and the scattered light from the revolving mirror. The former may be eliminated, as already mentioned, by slightly inclining the revolving mirror,

FROM MICHELSON, "STUDIES IN OPTICS" (UNIVERSITY OF CHICAGO)

FIG. 5.—MICHELSON'S LATER APPARATUS FOR DETERMINING THE VELOCITY OF LIGHT: THE UPPER FIGURE SHOWING THE COMPLETE DISPOSITION, AND THE LOWER FIGURE, THE APPARATUS AT THE MOUNT WILSON END IN MORE DETAIL

but to avoid scattered light, it is essential that the return ray be received on a different surface from the outgoing. Again, in order to avoid difficulty in maintaining the distant mirror perpendicular to the incident light, the return of the ray to the home station may be accomplished exactly as in Fizeau's experiment, the only precaution required being the very accurate focussing of the beam on a small plane (or better, concave) mirror at the focus at the distant collimator. Fig. 5 shows the arrangement of apparatus which fulfilled these requirements.

In Michelson's experiments the speed of rotation (529 rev. per second) of the revolving mirror was determined by an electric tuning fork. The fork was compared, before, and after every set of observations, with a free pendulum, whose rate was found by comparison with an invar pendulum furnished and rated by the Coast and Geodetic Survey. The 1924 results, gave, for the velocity of light in air 299,735 km. per second; the 1925 results—using the same fork and pendulum—299,690 km. per second; and a third series, in which the electric fork was replaced by a free fork maintained by an *audion circuit*, gave 299,704 km. per second. Applying the correction of 67 km. for reduction to vacuo gives, finally, 299,771 km. per second.

Observations with the same lay-out were resumed in the summer of 1926, with an assortment of revolving mirrors. The first of these was the small octagonal glass mirror used in the preceding work; the result obtained this year was 299,813 km. per second. The other mirrors were a steel octagon, a glass 12-sided, a steel 12-sided, and a glass 16-sided. The final results are summarized in Table A.

TABLE A

Mirror	Number of observations	Velocity of light in vacuo in kms. per sec.
Glass octagon	576	299,797
Steel octagon	195	299,795
Glass 12-sided	270	299,796
Steel 12-sided	218	299,796
Glass 16-sided	504	299,796

Weighted mean: 299,796 ± 1 km. per second.

VELOCITY AND WAVE-LENGTH

The experimental measures thus far cited have been primarily those of the velocity of light in air, the reduction to a vacuum being derived from theory alone. The fundamental constant at the basis of the whole theory is the speed of light in a vacuum, such as the celestial spaces. The question of the relation between the velocity in vacuo, and in a transparent medium of any sort, belongs to the domain of physical optics (*see* LIGHT). We shall in the present part of the article confine ourselves to the experimental results. With the theory of the effect of a transparent medium is associated that of the possible differences in the speed of light of different colours.

The question whether the speed of light in vacuo varies with its wave-length seems to be settled with entire certainty by observations of variable stars. These are situated at different distances, some being so far that light must be several centuries in reaching us from them. Were there any difference in the speed of light of various colours it would be shown by a change in the colour of the star as its light waxed and waned. The light of greatest speed preceding that of lesser speed would, when emanated during the rising phase, impress its own colour on that which it overtook. The slower light would predominate during the falling phase. If there were a difference of 10 minutes in the time at which light from the two ends of the visible spectrum arrived, it would be shown by this test. As not the slightest effect of the kind has ever been seen, it seems certain that the difference, if any, cannot approximate to $\frac{1}{1,000,000}$ part of the entire speed. The case is different when light passes through a refracting medium. It is a theoretical result of the undulatory theory of light that its velocity in such a medium is inversely proportional to the refractive index of the medium. This being different for different colours, we must expect a like difference in the velocity.

Foucault and Michelson have tested these results of the undulatory theory by comparing the time required for a ray of light to pass through a tube filled with a refracting medium, and through air. Foucault thus found, in a general way, that there actually was a retardation; but his observations took account only of the mean retardation of light of all the wave-lengths, which he found to correspond with the undulatory theory. Michelson went further by determining the retardation of light of various wave-lengths in carbon bisulphide. He made two series of experiments, one with light near the brightest part of the spectrum; the other with red and blue light. Putting V_0 for the speed in a vacuum and V_1 for that in the medium, his result was:

Yellow light	$V_0 : V_1 = 1{\cdot}758$
Refractive index for yellow	1·64
Difference from theory	+0·12.

The estimated uncertainty was only 0·02, or $\frac{1}{6}$ of the difference between observation and theory.

The comparison of red and blue light was made differentially. The colours selected were of wave-length about 0·62 for red and 0·49 for blue. Putting V_r and V_b for the speeds of red and blue light respectively in bisulphide of carbon, the mean result compares with theory as follows:

Observed value of the ratio V_r, V_b	1·0245
Theoretical value (Verdet)	1·025.

This agreement may be regarded as perfect. It shows that the divergence of the speed of yellow light in the medium from theory, as found above, holds through the entire spectrum.

Lord Rayleigh found the following explanation of the discrepancy. In the method of the toothed wheel the disturbances are propagated in the form of isolated groups of wave-trains. Let fig. 6 represent such a group of wave-trains. The wave-velocity is that required to carry a wave crest A to the position of the crest B in the wave period (T). But when a flash of light like that measured passes through a refracting medium, the front waves of the flash are continually dying away, as shown at the end of the figure, and the place of each is taken by the wave following. A familiar case of this sort is seen when a stone is thrown into a pond. The front waves die out one at a time, to be followed by others, each of which goes further than its predecessor, while new waves are formed in the rear. Hence the group, as represented in the figure by the larger waves in the middle, moves as a whole more slowly than do the individual waves. The

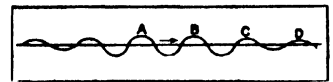


FIG. 6.—DIAGRAM INDICATING THE DIFFERENCE BETWEEN WAVE-VELOCITY AND GROUP-VELOCITY

simplest way of considering such a group analytically is to add two simple harmonic wave-trains of slightly different frequency. When the speed of light is measured the result is not the wave-velocity as above defined, but something less, because the result depends on the time of the group passing through the medium. It can be shown that this applies to measurements made with the revolving mirror method as well as the toothed wheel method. This lower speed is called the group-velocity of light. The relationship of the group velocity to the wave velocity is shown in the equation:

$$V' = V\left(1 - \frac{\lambda}{V}\frac{dV}{d\lambda}\right)$$

where V' = group velocity, V = wave velocity, and λ = wave length. In a vacuum there is no dying out of the waves, so that the group-speed and the wave-speed are identical. The value of $\left(1 + \frac{\lambda}{V}\frac{dV}{d\lambda}\right)$ for carbon disulphide for the mean wave-length of the visible spectrum is 0·93. Hence

$$\frac{V_0}{V'} = \frac{V_0}{V}\left(1 + \frac{\lambda}{V}\frac{dV}{d\lambda}\right) = \frac{1\cdot64}{\cdot93} = 1\cdot76$$

which agrees with the experimental order quoted above.

BIBLIOGRAPHY.—A good general account of the experimental determination of the velocity of light is given in Preston, *The Theory of Light*, ch. xix. (5th ed., 1928). *See* also A. A. Michelson, *Studies in Optics* (1927). For a detailed account of Michelson's Mt. Wilson experiments *see Astrophysical Journal*, vol. lxv., p. 1 (1927). For a discussion of the various determinations *see* M. E. J. Gheury de Bray, *Nature*, vol. cxx. (1927). (A. A. M.)

VELOUR. The term velour (French for velvet) refers in particular to a large variety of woollen textures, and in general to several varieties both of woollen and cotton textures, and also to union fabrics, that are formed with a short furry nap or fur on either one side only or on both sides of the fabric, and developed, subsequent to weaving, by operations of milling and raising. Velour fabrics are characterized by a soft and full "handle" or "feel" and used as dress and costume fabrics, suitings, coatings and dressing gowns according to the texture. Velour is also applied as a general description of many other varieties of fabrics produced from a mixture both of wool and cotton, and to some varieties of all-cotton fabrics on which there is developed the characteristic "velour finish," after weaving.

The nap or pile surface of a velour fabric, produced by milling and raising, is not analogous to the velvet or plush pile of true velvet or plush, nor of velveteen (cotton velvet) in which the pile is produced by a series of tufts, that stand erect from a foundation texture, and are developed by severing the pile warp threads, in velvet and plush fabrics (*q.v.*), and the pile picks of weft in velveteen or cotton velvet.

VELSEN, a town of Holland, in the province of North Holland, close to Ymuiden, with which it forms a single municipal administration. Pop. (1927), 35,103. Velsen is situated on the North sea canal, and forms the port of entrance for Amsterdam.

VELVET. The term "velvet" applies strictly to the true type of the plain silk velvet of the lighter textures, constructed with a short "velvet" or plush pile surface, which is developed during weaving by severing certain warp threads of silk, thereby causing the severed threads to stand erect in the form of short tufts from a substantial foundation texture of silk, cotton or other textile material. Velvet has been greatly in the popular favour for many centuries as a dress material, also for garments for use on such occasions as state, social and religious ceremonies and an infinite variety of uses such as curtain drapery, hangings and furniture upholstery and many other purposes. The richest velvet fabrics are those of Dutch (Utrecht) and Genoese manufacture, and that variety known as "collar velvet" for use specially in making the collars of men's overcoats. The velvet pile warp consists of pure silk yarn, though the foundation texture may be woven from a silk warp and cotton weft, or all cotton for both warp and weft.

One of the oldest examples of velvet is that forming part of a 14th century embroidered cape in the college of Mount St. Mary, Chesterfield. In the earliest of the inventories relating to church vestments, there is a reference, in St. Paul's, London, A.D. 1295, to the use of "velvet" with its kindred web "fustian," for "chasubles": while in that of Exeter cathedral, in 1327, velvet, for the first time is mentioned as being "in two pieces not made up, of which some yards had been then sold for vestment making."

Velvet Weaving.—Velvet fabrics of the lighter textures are woven in hand-looms and produced from two distinct series of warp threads and one series of weft threads, viz., "ground" threads to form the foundation texture, and "pile" threads to form the pile, arranged in the fabric in the order of two ground threads and one pile thread, uniformly. Also, each system of warp threads is contained on a separate warp beam or roller in order to permit of the tension and rate of delivery of each system being adjusted and controlled independently. This provision is essential by reason of the two warps contracting at different rates during weaving; that of the pile warp being considerably greater than that of the ground warp, and in the ratio of about 6 or 8 to one, respectively, according to the length or depth of the pile.

During weaving, the pile is developed by raising all the pile warp threads whilst the ground threads remain down, and then inserting through the warp shed thus formed, a long, thin steel wire, having a narrow groove formed in the upper edge, and extending for its entire length. This wire, termed a "pile wire" is then beaten-up by the reed right up to the "fell" of the cloth, just as an ordinary pick of weft, after which (in one velvet structure), three picks of weft are inserted in succession. These interweave with the ground warp threads on the plain calico principle to produce a firm foundation texture for the tufts of pile. Also, for the first and third of these picks, all pile warp threads are left down, but are raised on the second or intermediate pick, thereby interweaving these threads on the principle known as "fast" or "lashed" pile which binds them very securely to the foundation texture, with less risk of their accidental withdrawal, when the fabric is in use. After these three picks of weft are inserted, another pile wire is inserted in the warp shed, formed, as before, by raising all pile warp threads only and leaving down all ground threads. Then follow the next three ground picks in succession, and so on, in the same regular sequence, uniformly.

Producing the Pile.—From this brief description, it will be apparent that all the pile warp threads simply bend over the grooved pile wires and thus form a horizontal row of loops extending across the entire width of the fabric, between the two selvedges, while those wires virtually constitute thick picks of weft which, along with the three fine picks, are all beaten-up close together, by the reed, in the usual manner. After the second pile wire has been inserted, and followed by the three ground picks, the weaver now releases the first wire by severing, with a knife specially adapted for that purpose, all the pile threads that pass over it. This wire is then removed and inserted in the next pile warp shed to be followed by three more ground picks, after which the second wire is also released, and removed to be again inserted in the next following pile warp shed, and so on, continuously. The severing of the loops formed by the pile warp threads causes these to stand erect as short tufts and thus produce the pile surface.

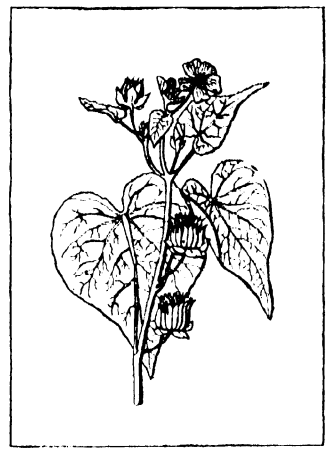
The instrument employed by a velvet weaver, for cutting the pile warp threads, consists of a special form of knife blade, bent at an angle and fixed adjustably in a frame described as a "trevette." This frame serves both as a handle and guide for the blade, of which the thin and sharp edge is inserted by the weaver into the narrow groove of the pile wires, and drawn quickly, by the right hand, from the left selvedge to the right, with the rear side of the "trevette" bearing against the pile wire last inserted, to serve as a guide, whilst the knife edge passes along the groove of the pile wire nearest the weaver.

Types of Velvet.—Velvet fabrics also comprise many other varieties ranging from the light, plain textures employed for personal adornment, to the heavier and stronger figured textures for furniture upholstery, curtain drapery, mats, rugs, and similar articles of a more durable character. These comprise such types as Utrecht velvet, "frieze" velvet, "moquette" velvet, and others of a similar kind. Many of these varieties of figured velvets, with the pile produced from mohair and wool, are woven in power-looms

furnished with special mechanism adapted to insert the "pile wires" into the warp sheds, and afterwards withdraw them from the cloth, automatically.

Figured velvet fabrics are also sometimes embellished with both a cut or "velvet" pile and an uncut (*i.e.*, looped or "terry") pile, with very pleasing effect owing to the lighter and darker tones of colour resulting from the difference in the reflection of light from the "velvet" and "terry" pile surfaces, which appear to be of darker and lighter tones, respectively, although produced from warp threads of exactly the same material, colour and counts of yarn. Very beautiful varieties of figured, plush pile fabrics are those described as "embossed plush pile fabrics" which are described under "ARTIFICIAL SILK FABRICS" (*q.v.*). (H. N.)

VELVETEEN. One of the most important varieties of the type of fabrics comprised under the general description of "fustians" (*q.v.*). Such fabrics are virtually "cotton velvets" constructed with a short weft pile surface and bear a very close resemblance to the true velvets (*q.v.*) constructed with a warp pile of silk. Although "velveteen" and "velvet" have a similar general appearance, they are each constructed on distinctly different principles of fabric structure.



Before being submitted to the operation of fustian cutting, all velveteen fabrics have a smooth and even weft surface very similar to that of ordinary cotton weft-face satin textures known as "sateen" (*q.v.*), and may be made to assume, during that operation, either a plain pile surface uniformly, or else a ribbed or corded surface with the ribs extending lengthwise of the fabric, *i.e.*, in the direction of the warp threads. Although they comprise several different modifications in respect of their structural details, they all embody the same essential features in their construction. This consists of the development of a series of short tufts of weft pile on a foundation of the plain calico, a simple twill, or other elementary weave structure of a suitable character. They consist essentially of one series of warp threads and two series of weft threads, viz., "face" or pile picks and "back" picks, respectively, of the same kind of weft from a single shuttle. The warp threads and "back" picks are interwoven on some elementary principle to constitute the foundation texture, while the "face" or pile picks are allowed to "float" somewhat freely on the face, as in a sateen fabric, to be afterwards severed by the fustian knife, in order to develop the tufts of pile. Face and back picks may be employed in any suitable ratio ranging from two to as many as nine pile picks for each ground pick, and with the face picks floating loosely over from three to eleven warp threads chiefly according to the character of texture as regards the length (or depth) and density of the pile and the weight and quality of the fabric and its particular use.

Forming the Pile.—During the operation of fustian cutting, all the floating pile weft is severed by the fustian knife, thereby causing that weft to stand erect, and thus form the short tufts of pile which lie in close formation and thus develop the characteristic velvet or plush pile over the entire surface of the fabric.

The picks are cut by the fustian knife. This knife-blade is formed with a very fine and sharp cutting edge at the extreme end of a long, square, steel shank inserted in a wooden haft to be held by the fustian cutter. After the velveteen fabric has been prepared in a suitable manner for cutting and stretched taut in a frame for that purpose, the fustian cutter, commencing at one selvedge, proceeds to cut that stretch of cloth one "race" or "run" at a time, taking each "race" in succession.

Varieties of Velveteen.—The different varieties of velveteen are distinguished chiefly by the particular weave structure on which the foundation texture is based. Hence, they are described as "plain," or "tabby-back"; "jean" or "jeanette-back"; and "Genoa-back" velveteens. The "tabby-back" variety signifies a foundation texture based on the plain calico weave; while "jean-back" signifies those based on the three-end ($\frac{2}{1}$) regular twill weave, as indicated in the design fig. 3; and "Genoa-back" those based on the four-end two-and-two ($\frac{2}{2}$) regular twill weave; while there are many other weaves employed in their construction. In addition to these variations, some velveteens are also constructed as "fast" or "lashed" pile velveteen, from the method of interweaving the picks of pile weft with the warp threads in such a manner that the tufts of pile are thereby interlocked or "lashed" more securely in the foundation texture. Thus, instead of each tuft of pile being looped underneath only one warp thread by the usual method, each tuft in a "lashed-pile" velveteen intersects with three warp threads in succession.

See H. Nisbet, *Grammar of Textile Design* (1927). (H. N.)

BY COURTESY OF THE IOWA GEOLOGICAL SURVEY

VELVET WEED OR INDIAN MALLOW, (ABUTILON THEOPHRASTI), SHOWING FLOWERS AND SEED-PODS

VELVET-WEED (*Abutilon Theophrasti*), an annual velvety-hairy plant of the mallow family (Malvaceae, *q.v.*), known also as Indian mallow, native to southern Asia and widely naturalized in the warmer parts of the United States, often becoming a pestiferous weed. It grows from 3 ft. to 6 ft. high, with large, heart-shaped leaves, yellow flowers, and a close head of beaked seed-pods.

VENAFRUM, an ancient town of Campania, Italy, close to the boundaries of both Latium Adjectum and Samnium. Its site is occupied by the modern Venafro, a village with 4,353 inhabitants (1921), on the railway from Isernia to Caianello, 15 m. S.W. of the former, 658 ft. above sea-level. Ancient authors tell us but little about it, except that it was one of those towns governed by a prefect sent yearly from Rome, and that in the Social War it was taken by the allies by treachery. Augustus founded a colony there and provided for the construction of an aqueduct (*cf.* the long decree relating to it in *Corp. Inscr. Lat.* x. No. 4842). It seems to have been a place of some importance. Its olive oil was the best in Italy, and Cato mentions its brickworks and iron manufactures. The original line of the Via Latina probably ran through Venafrum, making a détour, which the later road seems to have avoided (*cf.* LATINA, VIA). Rufrae was probably dependent on it. Roads also ran from Venafrum to Aesernia and to Telesia by way of Allifae. Of ancient remains hardly anything is left—some traces of an amphitheatre and fragments of polygonal walls only. (T. As.)

VENAISSIN, formerly a province of France, bounded on the north and north-east by Dauphiné, on the south by the Durance, on the east by Provence, and on the west by the Rhône. It comprises the present department of Vaucluse. Its capital is Carpentras (*q.v.*).

Venaissin is a picturesque territory, varying in scenery between the foothills of the Alps and magnificent plains, which are irrigated by canals supplied by the Rhone, the Durance and the Sorgue.

The Comtat-Venaissin (*Comitatus Venassinus*), the territory of the Gallic people the Cavares, belonged first to the counts of Provence, and then to the counts of Toulouse. Ceded to the pope in 1218 by Raymond VII. count of Toulouse, and again in 1274 by Philip the Bold, it was only united to France in 1791. The town of Avignon (*q.v.*), anciently distinct from the Comtat-Venaissin, was incorporated in it by Pope Clement VI. at the beginning of the 14th century. Avignon, a bishopric since the 1st century, became an archbishopric in 1475. Carpentras was a bishopric from 483 till 1805.

For history *see* L. Loubet, *Carpentras et le Comtat-Venaissin avant et après l'annexion* (1891).

VENANTIUS: *see* FORTUNATUS, VENANTIUS HONORIUS CLEMENTIANUS.

VEND, LIMITATION OF THE, the name of the operations of a combination of north of England colliery owners, which existed between 1771 and 1844, formed for the purpose of limiting the supplies of coal to consumers to raise prices.

The system of price control by coal owners using the ports of the Tyne, the Wear and the Tees, began as early as 1665 and became systematic in 1771. The owners established a control office at

Newcastle-on-Tyne with what is described by Porter in his *Progress of the Nation* as "a very costly establishment of clerks and agents." The governing committee held regular meetings at which the quantities to be sold by each colliery were determined and the prices to the consumer fixed. By this means, during a period of nearly three-quarters of a century, every British coal consumer using seaborne coal was heavily taxed. Moreover, as the limitation of the vend only applied to coal shipments to London, which was then the great market for seaborne coal, and not to shipments made to foreign countries, the system taxed British consumers while cheapening coal prices to foreign consumers.

The limitation of the vend became the subject of a number of parliamentary enquiries. It was examined by parliamentary committees in 1800, 1829, 1830 and 1836 and finally expired in 1844.

VENDACE (*Coregonus vandesius*), a small fish of the salmon family, from the lakes of Lochmaben, in Dumfriesshire, Scotland; the name is also given to an allied form (*C. gracilior*), from Derwentwater and Bassenthwaite. These differ from other British species in having the lower jaw prominent; the scales are larger than in related species from the Arctic ocean and the countries round the Baltic. (*See* WHITEFISH, SALMON AND SALMONIDAE.)

VENDÉE, a maritime department of western France, formed in 1790 out of Bas-Poitou, and taking its name from an unimportant tributary of the Sèvre Niortaise. It is bounded by Loire-Inférieure and Maine-et-Loire on the north, by Deux-Sèvres on the east, by Charente-Inférieure on the south and by the Atlantic ocean on the west for 93 m. Pop. (1926) 395,602. Area, 2,690 square miles. The islands of Yeu (area, 8½ sq.m.) and Noirmoutier are included. The department stretches from the Hauteurs de la Gâtine (748 ft.) in the north-east down the wooded slopes of the Bocage Vendéen to the plain bordered towards the sea by the Marais, largely salt-marshes reclaimed during the last four centuries. The Gâtine is a south-east to north-west axial line of the Armorican system, and the Bocage on its flank is formed mainly of Palaeozoic rocks, but the plain on the edge of the Marais is of Jurassic limestone. The three chief rivers are the Sèvre Nantaise, draining the Gâtine longitudinally, the Lay, and, in the south, the Sèvre Niortaise. The climate is that of the Girondine region, mild and damp, the temperature rarely rising above 77° or falling below 18° F; 120 to 150 days of rain give an average annual rainfall of 25 in. The woodland is colder than the plain, and the marsh is unhealthy.

Vendée is served by the Ouest-État railway and has 81 m. of navigable rivers and canals. The department forms the diocese of Luçon, has its court of appeal and educational centre at Poitiers, and is in the district of the XI. Army Corps (Nantes). There are three arrondissements (La Roche-sur-Yon, Fontenay-le-Comte and Sables-d'Olonne), 30 cantons, and 306 communes. The chief towns are La Roche-sur-Yon, the capital, Les Sables-d'Olonne, Fontenay-le-Comte and Luçon (*q.v.*). Foussais, Nieul-sur-l'Autise and Vouvant have Romanesque churches; Pouzauges has a stronghold of the 13th century; Maillezais has the ruins of a 12th century cathedral; Talmont and Tiffauges possess ruined castles; and Le Bernard and Noirmoutier have dolmens.

VENDÉE, WARS OF THE, a counter-revolutionary insurrection which took place during the French Revolution (*q.v.*), not only in Vendée proper but also in Lower Poitou, Anjou, Lower Maine and Brittany. The district was mainly inhabited by peasants; it contained few important towns, and the *bourgeois* were but a feeble minority. The ideas of the Revolution were slow in penetrating to this ignorant peasant population, which had always been less civilized than the majority of Frenchmen, and in 1789 the events which roused enthusiasm throughout the rest of France left the Vendéans indifferent. Presently, too, signs of discontent appeared. The priests who had refused to submit to the Civil Constitution of the Clergy perambulated these retired districts, and stigmatized the revolutionists as heretics. In 1791 two "representatives on mission" informed the Convention of the disquieting condition of Vendée, and this news was quickly followed by the exposure of a royalist plot organized by the marquis de La Rouërie.

The signal for a widespread rising was the introduction of conscription acts for the recruiting of the depleted armies on the eastern frontiers. In February 1793 the Convention decreed a levy on the whole of France, and on the eve of the ballot the Vendée, rather than comply with this requisition, broke out in insurrection. In the month of March 1793 the officer commanding at Cholet was killed, and republicans were massacred at Machecoul and St. Florent. Giving rein to their ancient antipathy, the revolted peasantry attacked the towns, which were liberal in ideas and republican in sympathies.

These first successes of the Vendéans coincided with grave republican reverses on the frontier—war with England, Holland and Spain, the defeat of Neerwinden and the defection of Dumouriez. The *émigrés* then began to throw in their lot with the Vendéans. Royalist nobles like the marquis de Bonchamp, Charette de la Contrie, Gigot d'Elbée, Henri de la Rochejaquelein and the marquis de Lescure placed themselves at the head of the peasants. Although several of these leaders were Voltairians, they held up Louis XVI., who had been executed in Jan. 1793, as a martyr to Catholicism, and the Vendéans, who had hitherto styled themselves the Christian Army, now adopted the name of the Catholic and Royal Army.

The Convention took measures against the *émigrés* and the refractory priests. By a decree of March 19, 1793, every person accused of taking part in the counter-revolutionary revolts, or of wearing the white cockade (the royalist emblem), was declared an outlaw. The prisoners were to be tried by military commissions, and the sole penalty was death with confiscation of property. The Convention also sent representatives on mission into Vendée to effect the purging of the municipalities, the reorganization of the national guards in the republican towns and the active prosecution of the revolutionary propaganda. These measures proving insufficient, a decree was promulgated on April 30, 1793, for the despatch of regular troops; but, in spite of their failure to capture Nantes, the successes of the Vendéans continued.

At the end of Aug. 1793, the republicans had three armies in the Vendée—the army of Rochelle, the army of Brest and the *Mayençais*; but their generals were either ciphers, like Ronsin, or divided among themselves, like Rossignol and Canclaux. They were uncertain whether to cut off the Vendéans from the sea or to drive them westwards; and moreover, their men were undisciplined. Although the peasants had to leave their chiefs and work on the land, the Vendéans still remained formidable opponents. They were equipped partly with arms supplied by England, and partly with fowling-pieces, which at that period were superior to the small-arms used by the regular troops, and their intimate knowledge of the country gave them an immense advantage.

The dissensions of the republican leaders and the demoralizing tactics of the Vendéans resulted in republican defeats at Chantonnay, Torfou, Coron, St. Lambert, Montaigu and St. Fulgent. The Convention resolved to bring the war to an end before October, and placed the troops under the undivided command, first of Jean Léchelle and then of Louis Turreau, who had as subordinates such men as Marceau, Kléber and Westermann. On Oct. 7 the various divisions concentrated at Bressuire, took Châtillon after two bloody engagements, and defeated the Vendéans at Cholet, Beaupréau and La Tremblaye. After this repulse, the royalists, under Stofflet and La Rochejaquelein, attempted to rouse the Cotentin and crossed the Loire. Beaten back at Granville, they tried to re-enter the Vendée, but were repulsed at Angers. They re-formed at Le Mans, where they were defeated by Westermann, and the same officer annihilated the main body of the insurgents at Savenay (Dec. 1793).

Regular warfare was now at an end, although Turreau and his "infernal columns" still continued to scour the disaffected districts. After the 9th Thermidor attempts were made to pacify the country. The Convention issued conciliatory proclamations allowing the Vendéans liberty of worship and guaranteeing their property. Gen. Hoche applied these measures with great success. He restored their cattle to the peasants who submitted, "let the priests have a few crowns," and on July 20, 1795, annihilated an *émigré* expedition which had been equipped in England and had seized Fort Penthièvre and Quiberon. Treaties were concluded at La

Jaunaie (Feb. 15, 1795) and at La Mabillaie, and were fairly well observed by the Vendéans; and nothing remained but to cope with the feeble and scattered remnant of the Vendéans still under arms, and with the Chouans (*q.v.*). On July 30, 1796, the state of siege was raised in the western departments.

During the Hundred Days there was a revival of the Vendéan war, the suppression of which occupied a large corps of Napoleon's army, and in a measure weakened him in the northern theatre of war. (*See* WATERLOO CAMPAIGN.)

In 1832 again an abortive insurrection broke out in support of the Bourbons, at the instigation of the duchess of Berry; the Vendéan hero on this occasion was the baron de Charette.

There are numerous articles on the Vendéan insurrection of 1793 in the *Revue du Bas-Poitou, Revue historique de l'Anjou, Revue de Bretagne, de Vendée et d'Anjou, Revue historique de l'Ouest, Revue historique et archéologique du Maine,* and *La Vendée historique. See* also R. Bittard des Portes, "Bibliographie historique et critique des guerres de Vendée et de la Chouannerie" in the *Revue du Bas-Poitou* (1903 *seq.*); C. L. Chassin, *Études sur la Vendée et la Chouannerie* (*La Préparation de la guerre—La Vendée patriote—Les Pacifications de l'Ouest*) (Paris, 1892 *seq.*), 11 vols. (the best general work on the subject); C. Port, *Les Origines de la Vendée* (Paris, 1888); C. Leroux-Cesbron, "Correspondance des représentants en mission à l'armée de l'ouest (1794–95)" in the *Nouvelle Revue rétrospective* (1898); Blachez, *Bonchamps et l'insurrection vendéenne* (Paris, 1902); P. Mautouchet, *Le Conventionnel Philippeaux* (Paris, 1901). On 1815 a modern work is *Les Cent Jours en Vendée; le général Lamarque,* by B. Lasserre (Paris, 1907); on 1832 see *La Vendée,* by Vicomte A. de Courson (1909). (R. AN.)

VENDÉMIAIRE, the name given during the French Revolution to the first month of the year in the Republican calendar (from Lat. *vindemia,* vintage). Vendémiaire began on Sept. 22, 23 or 24, and ended on Oct. 22, 23 or 24, according to the year, and was the season of the vintage in the wine districts of northern France. *See* CALENDAR.

VENDETTA, the custom of the family feud, by which the nearest kinsman of a murdered man was obliged to take up the quarrel and avenge his death. (Ital. from Lat. *vindicta,* revenge.) From being an obligation upon the nearest, it grew to be an obligation on all the relatives, involving families in bitter private wars. In primitive communities, the injury done was held to be more than personal, a wrong done to the whole *gens.* The term originated in Corsica, where the vendetta long played an important part in the social life. If the murderer could not be found, his family were liable to fall victims to the vendetta.

VENDÔME, LOUIS JOSEPH, DUC DE (1654–1712), marshal of France, was the son of Louis, 2nd duke of Vendôme, and the great-grandson of Henry IV. and Gabrielle d'Estrées. Entering the army he distinguished himself in the Dutch wars, and by 1688 had risen to the rank of lieutenant-general. In the war of the Grand Alliance he rendered conspicuous service and in 1695, in command of the army operating in Catalonia, he took Barcelona. Soon afterwards he received the marshalate. In 1702, after the first unsuccessful campaign of Catinat and Villeroi, he was placed in command of the Franco-Spanish army in Italy. (*See* SPANISH SUCCESSION WAR.) During three campaigns in that country he proved a worthy antagonist to Prince Eugene, whom at last he defeated at Cassano. Next year he was sent to Flanders to repair the disaster of Ramillies with the result that his successors Marsin and Philip of Orleans were totally defeated, while in the new sphere Vendôme was merely the mentor of the pious and unenterprising duke of Burgundy, and was unable to prevent the defeat of Oudenarde. He retired in disgust to his estates, but was soon summoned to take command of the army of Philip in Spain. There he won his last victories, crowning his work with the battle of Villaviciosa. Before the end of the war he died suddenly at Vinaros on June 11, 1712.

VENDÔME, a town of north-central France, capital of an arrondissement in the department of Loir-et-Cher, 22 m. N.W. of Blois by rail. Pop. (1926) 7,383. Vendôme (*Vindocinum*) appears originally to have been a Gallic oppidum, replaced later by a feudal castle, around which the modern town arose. Christianity was introduced by St. Bienheuré in the 5th century, and the important abbey of the Trinity was founded about 1030. When the reign of the Capetian dynasty began, Vendôme was the chief town of a countship belonging to Bouchard, called "the Venerable." The succession passed by various marriages to the houses of Nevers, Preuilly and Montoire. Bouchard VII., count of Vendôme and Castres (d. *c.* 1374), left as his heiress his sister Catherine, the wife of John of Bourbon, count of la Marche. The countship of Vendôme was raised to the rank of a duchy and a peerage of France for Charles of Bourbon (1515); his son Anthony of Bourbon, king of Navarre, was the father of Henry IV., who gave the duchy of Vendôme in 1598 to his natural son Caesar (1594–1665). Caesar, duke of Vendôme, had as his sons Louis, duke of Vendôme (1612–69), who married a niece of Mazarin, and Francis, duke of Beaufort. The last of the family in the male line (1654–1712) was Louis XIV.'s famous general, Louis Joseph, duke of Vendôme (*q.v.*).

Vendôme stands on the Loir, which here divides and intersects the town. To the south stands a hill on which are ruins of the 11th century castle of the counts of Vendôme. The abbey-church of the Trinity (12th to 15th century) has a fine façade in the florid Gothic style and a transitional 12th century belfry, with a stone steeple, stands isolated in front of the church. Abbey buildings of various periods lie round the church. The church of La Madeleine (15th century) is surmounted by a stone spire, an indifferent imitation of that of the abbey. Of the church of St. Martin (16th century) only the tower remains. The town hall occupies the old gate of St. George, with two large crenelated and machicolated towers, connected by a pavilion. The 15th century chapel of the ancient hospital of St. Jacques, in the most florid Gothic style, is preserved.

VENEER, a thin sheet of superior wood, covering the surface of inferior wood. Veneers may be sliced with a knife (*knife-cut*) or cut with a saw (*saw-cut*) from a section of a tree (*flitch*).

The art of producing and using veneers dates back to the earliest days of civilization, and it may be looked upon even as a standard of human development, since efficient veneering has always followed the wake of human progress. (*See* Wilkinson's *Manners and Customs of the Ancient Egyptians,* Perrot and Chipiez' *History of Art in Chaldea and Assyria,* etc.) Intarsia and *marquetry* work are closely allied to and inter-dependent upon the art of veneering.

In the usual process of manufacture, the flitches are steamed before being cut, and the sheet of veneer thus obtained is carefully dried. Veneers may be cut along the grain, through the log, or from cross-sections of the log; the figure and design of the veneer obtained from the different methods employed vary widely and the art of veneering consists as much in the most effective utilization of the log as in the careful and suitable application and matching of the veneers afterwards. Veneers are also produced by means of the rotary cutting process as a raw material for *plywood.* A part of a log is inserted lengthwise between two pins on a rotating lathe, and a knife, pressed against it, peels off an endless ribbon of veneer. (*See* PLYWOOD.)

See Sidney J. Duly, *Timber and Timber Products* (1924); E. Vernon Knight and Meinrad Vulpi, *Veneers and Plywood* (N.Y., 1927); E. Brocard, *L'Art de découper le bois comprenant également la Marqueterie et la Sculpture Simple* (Paris, 1873). (A. MOR.)

VENER, the largest lake in Sweden and the third largest in Europe; area 2,149 sq.m.; maximum length 87 m.; maximum breadth 44 m.; maximum depth 292 ft. The surface of the lake is normally 144 ft. above the sea but may rise 10 ft. or more higher, for the lake receives numerous streams, the largest being the Klar, which drains the forests of Vermland and Kopparberg to the north. It is drained by the Göta river to the Cattegat. It is divided into two basins by two peninsulas and a group of islands, the western half being Lake Dalbo. The northern shores are high, rocky and in part wooded, the southern open and low, though isolated hills occur, such as the Kinnekulle (1,007 ft.).

By means of the Dalsland Canal from Köpmannabro, midway on the west shore of Dalbo, the lake, which is busy in the traffic in timber, iron and agricultural produce, has communication with Fredrikshald in Norway; and it is traversed from Venersborg on the south to Sjötorp on the east by the Göta (*q.v.*) Canal route.

The principal lake-ports are—on the north shore Carlstad and Cristinehamn, with iron-works and tobacco factory; on the east Mariestad, chief town of the district of Skaraborg; on the south Lidköping, and Venersborg with its iron foundries, tanneries and match and paper factories.

VENERABLE, worthy of honour, respect and reverence, especially a term applied to dignified or honourable age [Lat. *venerabilis,* worthy of reverence]. It is specifically used as a title of address given to archdeacons in the Anglican Church. It was naturally a term of respectful address from early times; thus St. Augustine (*Epist.* 76, 88, 139) cites it of bishops, and Philip I. of France was styled *venerabilis* and *venerandus* (*see* Du Cange, *Gloss.* s.v. *Venerabilitas*). In the Roman Church the granting of the title "venerable" is the first step in the long process of the canonization of saints (*see* CANONIZATION).

VENEREAL DISEASES, a general term for the diseases resulting from impure sexual intercourse. Three distinct affections are included under this term—gonorrhoea, local contagious ulcers, known as soft chancres, and syphilis. They are three distinct diseases, due to different causes. Broadly speaking, gonorrhoea attacks the mucous membranes, especially that of the urethra, the vagina, uterus and Fallopian tubes; soft chancres attack the mucous membranes and the skin; syphilis, after a short local manifestation, affects the whole body.

Though these three affections generally result from impure sexual intercourse, there are other methods of contagion, as when the accoucheur is poisoned whilst delivering a syphilitic woman, the surgeon when operating on a syphilitic patient, the wet-nurse who is suckling a syphilitic infant, and so on. An individual may be attacked by any one or any two of the three, or by all at the same time, as the result of one and the same connection. But they do not show themselves at the same time; they have different stages of incubation. In gonorrhoea and soft chancre the first symptoms appear as a rule three or four days after inoculation; in syphilis, the period of incubation is twenty-eight days, though it may be much longer.

GONORRHOEA

Gonorrhoea is a specific inflammation of the mucous membrane of the urethra and other passages caused by M. gonorrhoeæ, a diplococcus discovered by Neisser and often called the gonococcus.

The germs find entrance during coitus and multiply at enormous rate, spreading to all the glands and crevices of the membrane, and setting free in their development a toxin which causes great irritation of the passage with inflammation and swelling. They remain quietly incubating for three or four days, or even longer; then acute inflammation comes on, with profuse discharge of thick yellow matter, with much scalding during micturition, and there may be so much local pain that it is difficult for the person to move about. Microscopic examination of the discharge shows abundant pus corpuscles and epithelial cells from the membrane, together with swarms of intra- and extra-cellular diplococci (gonococci).

The inflammatory process may extend backwards and give rise to acute prostatitis (*see* BLADDER AND PROSTATE, DISEASES OF), with retention of urine; to the duct of the testes and give rise to acute epididymitis (swollen testicle); and to the bladder, causing acute cystitis. It may also cause local abscesses, or, by irritation, set up crops of warts.

In ten days or a fortnight the inflammation gradually subsides, a thin watery discharge remaining which is known as *gleet.* But inasmuch as this discharge contains gonococci it may, though scarcely noticeable, set up acute specific inflammation in the opposite sex.

In the case of the female the inflammation is apt to extend to the uterus and along the Fallopian tubes, perhaps to give rise to an abscess in the tube (pyosalpinx) which, bursting, may cause fatal peritonitis.

A lingering gleet may be due to the presence of a definite ulceration in the urethra, and this, being chronic, is accompanied by the formation of much fibrous tissue which contracts and causes narrowing of the urethra, or stricture. Thus gleet and stricture are often associated, and the occasional passage of a large bougie may suffice to cure both. Often, however, a stricture of the urethra proves rebellious in the extreme, and leads to diseases of the bladder and kidneys which may prove fatal.

One of the most important points in the management of a case of gonorrhoea is to prevent risk of the septic discharge coming into contact with the eye. If this happens, prompt and energetic measures must be taken to save the eye. If at the time of delivery a woman be the subject of gonorrhoea, there is great probability of the eyes of the infant being affected. The symptoms appear on the third day after birth, and the disease may end in complete blindness. The name of the disease is *ophthalmia neonatorum.* (*See* BLINDNESS.)

By the term *gonorrhoeal rheumatism* it is implied that the gonococci have been carried by the blood stream to one or more joints in which an acute inflammation has been set up. It is apt to occur in the third week of the disease, and may end in permanent stiffness of the joints or in abscess.

In rare cases the germs find their way to the cardiac valves, pleura or pericardium, setting up an inflammation which may end fatally.

For a man to marry whilst there is the slightest risk of his still being the subject of gonorrhoea is to subject his wife to the probability of infection, ending with chronic inflammation of the womb or of septic peritonitis. Yet it is often extremely difficult to say when a man is *cured.* That there is no longer any discharge does not suffice to show that he has ceased to be infective. Nothing less than repeated examinations of the urethral mucus by the microscope, ending in a negative result, should be accepted as evidence of the cure being complete. And these examinations should be made after he has returned to his former ways of eating, drinking and working.

LOCAL CONTAGIOUS ULCERS

Chancroid, Soft Chancre or Soft Sore is so named in contradistinction to the Hunterian sore of syphilitic infection, the great characteristic of which is its hardness. The soft chancre is a contagious ulcer of the genitals, due to the inoculation of the bacillus of Ducrey; and, provided that the specific germ of syphilis is not inoculated at the same time, the chancre is not followed by constitutional affection. In other words, the disease is purely local, and if some of the discharge of one of these ulcers is inoculated on another part of the body of the individual a sore of an exactly similar nature appears. This reproduction of the sore can be done over and over again on the same individual, always with the same result. But in the case of the Hunterian sore, inoculation of the individual from the primary sore gives no result, because the constitutional disease has rendered the individual proof against further infection. The soft sore is often multiple. It appears about three days after the exposure, and as it increases in size free suppuration takes place. Its base remains soft. In individuals broken down in health, the ulceration is apt to extend with great rapidity, and is then spoken of as *phagedaenic.*

Just as an individual may contract syphilis and gonorrhoea at the same connection, so also he may be inoculated simultaneously with the bacilli of the soft chancre and the spirochaete of syphilis. In this case the soft chancres appear, as usual, within the first three or four days, but though passing through the customary stages they may refuse quite to heal, or, having healed, they may become indurated in the second month, constitutional symptoms following in due course.

Bubo.—The bacilli from the soft sore may pass by the lymphatic vessels to the glands in the groin, when they set up inflammation.

SYPHILIS

The cause of syphilis, whether inherited or acquired, which can be demonstrated in the primary and various secondary lesions, and in the internal organs, is *Spirochaeta* or *Treponema pallida,* a motile protozoon of spiral form, from 4 to 20 μ in length and $\frac{1}{4}$ μ in diameter, with a flagellum at either extremity. Inoculations of the spirochaete in monkeys have produced the characteristic primary (Hunterian) sores, which have proved infective to other monkeys. And in the reproduced primary sores, as also in the

secondary lesions following them, the same specific micro-organism has been demonstrated. The organism can also be inoculated successfully into the testicles of rabbits.

The syphilitic virus is introduced at the seat of an abrasion either on the genital organs or on some other part of the surface of the body. It has been conveyed during a fight by abrasion of the skin covering the knuckle against the tooth of an adversary with secondary syphilis. The poison lies quiescent for an average period of four weeks. A cartilaginous, button-like hardness appears at the seat of inoculation. If this is irritated ulceration takes place; but ulceration is an accident, not an essential. The infection becomes systemic long before the chancre develops. The so-called period of quiescence does not exist. From the primary seat the system becomes infected. The virus, passing along the lymphatic vessels, attacks the nearest chain of lymphatic glands. If the original sore is in the genital organs, the glands in the groin are first attacked; if in the hand, the glands of the elbow or armpit; if on the lip, the glands below the jaw. The affected glands are indurated and painless; they may become acutely inflamed, just as the primary lesion may, but this, too, is an accident, not an essential. In due course the poison may affect the whole glandular system. Skin eruptions, often symmetrical, break out. Irritation of any mucous membrane is followed by papular eruptions with superficial ulceration, and in the later stages of the disease skin-eruptions, scaly, pimply, pustular or nodular in type, appear. These eruptions do not itch. The individual is as a general rule protected against a second attack of syphilis. In weakly people, in severe cases, or in cases that have not been properly treated, syphilitic deposits termed gummata are formed, which are very apt to break down and give rise to deep ulcerations.

Gummata.—The most characteristic form of the generalized syphilitic infection, which may not manifest itself for several years after the reception of the virus, is a nodular inflammatory formation in various organs—the liver, testes or brain, the muscles (tongue and jaw-muscles especially), the periosteum, the skin and the lungs. The deposits are called gummata from the tenacious appearance of the fresh-cut surface and of the discharge oozing from it. The structure consists of granulation-tissue in which necrosis occurs at various central points. One remarkable feature of the process is the overgrowth of cells in the inner coat of the arteries (*see* ARTERIES, DISEASES OF), within the affected area, which obliterate the vessel and are the chief cause of the central degeneration of the gumma. Gummata, and the ulcers left by them, constitute the *tertiary* manifestations of syphilis.

In a large proportion of cases only the secondary symptoms occur, and not the tertiary, the virus having presumably exhausted itself or been destroyed by treatment in the earlier manifestations.

Inherited Syphilis.—In the syphilis of the offspring it is necessary to distinguish two classes of effects—there are the effects of general intra-uterine mal-nutrition, due to the placental syphilis of the mother; and there are the true specific effects acquired by inheritance from either parent and conveyed in the sperm-elements or in the ovum. These two classes of effects are commingled in such a way as not to be readily distinguished; but it is probable that the ill-organized growth of bone, at the epiphysial line in the long bones (sometimes amounting to suppuration), and on the surfaces of the membrane-bones of the skull (*Parrot's nodes*) is a result of general placental mal-nutrition, like the corresponding errors of growth in rickets. The rashes and fissures of the skin, the snuffles and such-like well-known symptoms in the offspring are characteristic effects of the specific taint; so also the peculiar overgrowth in the liver, the interstitial pneumonia alba of the lungs and the like. It is in many cases some months after birth before the congenital syphilitic effects show themselves, while other effects come to light during childhood and youth.

The moist eruptions and ulcerations about the mouth and anus of the infant, as well as the skin affections generally, are charged with the spirochaetes and are highly contagious.

From the second to the sixth year there is commonly a rest in the symptoms that are regarded as characteristic, but the tibiae may become thickened from periostitis, or a joint may become swollen and painful.

The characteristic physiognomy gradually manifests itself if the child is not treated—the flattened nose, the square forehead, the radiating lines from the mouth, the stunted figure and pallid face. During the second dentition, the three signs, as pointed out by Jonathan Hutchinson, may be looked for—the notched incisor teeth of the upper jaw, interstitial corneitis and syphilitic deafness. Perforation of the soft or hard palate may occur, and ulcerations of the skin and cellular tissue. Destruction of the nasal bones, caries of the forehead and skull, of the long bones, may also take place.

Colles' Law.—A woman giving birth to a syphilitic infant cannot be inoculated with syphilis by the infant when she is suckling it; in other words, though the mother may have shown no definite signs of syphilis, she is immune; whereas the syphilitic infant put to the breast of a healthy woman may inoculate her nipple and convey syphilis to her. This is known as Colles' Law, and it is explained by the theory that, the mother's blood being already infected, her skin is proof against a local cultivation of germs in the form of a Hunterian sore.

General Remarks.—It by no means follows that because the infecting sore is small, unimportant or quickly healed, the attack, of which the sore is the first (*primary*) symptom, will be mild. Indeed, it not infrequently happens that the most serious forms of secondary or tertiary symptoms succeed a sore which was regarded as of such trivial nature that the individual declined to submit himself to treatment, or quickly withdrew himself from it to enter a fool's paradise. The advisability of ceasing from treatment should always be determined by the surgeon, never by the patient; treatment must be continued long after the disappearance of the secondary eruptions. It is the *disease* which the surgeon has to cure, not the *symptoms*. The patient is apt to think only of the symptoms.

"Is the disease curable?" The answer is: "Yes; beyond doubt." But the individual must be made to understand the necessity of his submitting himself to a prolonged course of treatment. A second question is whether, in the course of the disease, his hair will fall out, his body will be covered with sores and his face with blotches, and if his bones will be attacked. Here, again, the answer is that prompt submission to treatment will render all such calamities extremely improbable. Another question often put is whether the disease is contagious or infectious. During the primary and secondary stages he is infectious as far as his lesions are concerned. Obviously, if a man has a primary sore or a secondary eruption he should use his own pipe, razor, glass, cup or spoon, should refrain from kissing any one, and desist from sexual intercourse. If due care thus be taken no danger is likely to ensue.

Syphilis and Marriage.—The question as to how soon it would be safe for a person with secondary syphilis to marry is of extreme importance, and the disregard of it may cause lasting mental distress to the parent and permanent physical injury to the offspring. A man who finds himself to be the subject of secondary syphilis when he is engaged to be married would do well honourably to free himself from responsibility. But should a person who has been under regular and continuous treatment desire to marry, consent may be given when he has seen no symptoms of his disease for two full years. But even then no actual promise can be made that his troubles are at an end.

The transmission of syphilis to the third generation is quite possible, but it is difficult of absolute proof because of the chance of there having been intercurrent infection of the offspring of the second generation. (E. O.; X.)

GENERAL PREVENTIVE MEASURES

The period since 1910 has been marked by the commencement of a campaign which has developed into a world-war against venereal diseases. In this work Great Britain has taken a prominent part.

In 1913 a royal commission was set up to inquire into "the prevalence of venereal diseases in the United Kingdom, their effects on the health of the community, and the means by which those effects can be alleviated or prevented." The royal commission reported in 1916, and their recommendations were imme-

diately acted upon by the Local Government Board of England and Wales (now the Ministry of Health), and the public measures for combating venereal diseases in England and Wales are now as mentioned below, while in Scotland and Ireland the campaign is being conducted on the same principles.

Legislative Action.—1. By an Act of Parliament passed in 1917 the treatment of patients for venereal disease by others than registered medical practitioners and the sale without the prescription of a registered medical practitioner or the advertisement to the lay public of remedies for the treatment or prevention of venereal diseases are forbidden.

2. There are 193 centres chiefly in voluntary hospitals for the treatment, free of charge, of persons suffering from venereal disease.

3. Fourteen hostels exist for the care and treatment of females who are infected, and would, unless helped by shelter, become professional prostitutes.

4. Seven institutions are specially for the care of pregnant females who are infected.

5. Treatment of venereal disease is also provided in poor law institutions.

6. Arsenobenzol (salvarsan) compounds are given free of charge to medical practitioners qualified to administer these remedies.

7. Specimens from persons suspected to be suffering from venereal disease can be examined free of charge in 73 laboratories which have been approved for the purpose.

8. The work of educating the public in the dangers of venereal diseases and the importance of early and continued treatment is carried out by the British Social Hygiene Council (formerly the National Council for Combating Venereal Diseases), which receives from the Government a grant in aid of its expenses. Propagandist work is also undertaken by the county councils and county borough councils, either directly or in conjunction with the British Social Hygiene Council.

The arrangements for establishment of free treatment facilities for distribution of arsenobenzol compounds and for laboratory examinations are under the control of county councils and county borough councils, which receive from the Government 75% of their approved expenditure on this account.

Results Obtained.—Some idea of the results obtained may be gathered by comparing the returns of cases seen for the first time in 1920, when the numbers were highest, with those seen for the first time in 1924, as presented hereunder:—

Year	Syphilis	Soft Chancre	Gonorrhoea	Non-ven.	Total
1920	42,805	2,442	40,284	19,654	105,185
1924	22,010	1,098	31,272	18,842	73,222

The table discloses a substantial reduction in the number of cases of syphilis, and the figures indicate that the incidence of syphilis in the community has declined considerably. Similar results have been reported by other countries which have set up venereal-disease schemes on the principle of treating the infected. The attendance at the centres in 1920 was 1,488,514 and in 1924 had increased to 1,645,415.

Gonorrhoea.—No outstanding remedy has been discovered analogous to that of arsenobenzol in syphilis, but, particularly since 1914, improvements in detail have made the diagnosis and cure of gonorrhoea more certain. In diagnosis, improvements in methods of cultivating the gonococcus on artificial media have placed the surgeon on firmer ground when determining the question of cure. In treatment the practice of administering vaccines to raise the patient's resistance has become much more common. In complications of gonorrhoea, such as gonorrhoeal rheumatism and iritis, what is known as protein-shock therapy has proved useful.

The remedies employed in this form of treatment are quite varied; for example, colloidal silver or anti-typhoid vaccine injected into a vein; milk or turpentine injected into the muscles. They have the immediate effect of raising the patient's temperature and by the next day there is usually a definite improvement in the symptoms.

Another form of treatment which has been in use by a few for a number of years but is only now becoming more general is diathermy. (*See* ELECTRO-THERAPY.) The principle of its use in gonorrhoea and its complications is that the gonococcus is very sensitive to heat, being killed at temperatures which are supported with comparative ease by human tissues.

Good results have been obtained in gonorrhoea of females by this method, but undoubtedly its best effects are in epididymitis and in gonorrhoeal rheumatism in men. In gonorrhoeal rheumatism and iritis the reservoir from which the joints and eyes are continually being infected is commonly in the prostate and the seminal vesicles, both situated at the base of the bladder. The current is applied by means of an electrode placed in the rectum and is increased in strength until the patient feels the part becoming uncomfortably hot.

Soft Chancre or Chancroid.—The figures showing the new cases which have been seen at treatment centres indicate that chancroid is not now very prevalent in Great Britain. The treatment is now more conservative than formerly. The chancroid is viewed as possibly harbouring also the germs of syphilis, and with the object of avoiding any action which may prejudice the microscopical search for the more severe disease, the surgeon withholds for as long as possible the application of antiseptics.

When a bubo forms in the groin, a comparatively rare event under modern practice, it is more usual now to attempt to secure resolution by protein-shock therapy (*see* GONORRHOEA) and by aspiration of the abscess followed by injection into the abscess cavity of some drug which will lead to the destruction of the germs.

Detection of Syphilis.—Improvements in methods of detecting the germ, *Spirochaeta pallida*, under the microscope, viz., by dark-ground illumination, have made it possible to diagnose the disease very rapidly on the day it makes its first appearance. For the Wassermann and allied tests of blood and cerebro-spinal fluid for the presence of syphilis the article WASSERMANN REACTION should be consulted.

Great strides have been made in treatment since 1910 when Ehrlich introduced dioxy-diamino-arsenobenzol dihydrochloride, commonly known as "606" or salvarsan (*q.v.*), as a remedy for syphilis. The effect of a single dose of this remedy is usually to cause the spirochaetes to disappear from the discharge of syphilitic sores in 24 hours and syphilitic lesions heal with a rapidity which was a source of great wonder to those who had toiled in the treatment of syphilis with the help of only mercury and preparations of iodine.

The original preparation has largely been supplanted by a compound introduced by Ehrlich in 1912 under the name of neosalvarsan or "914," which is much more convenient to use and less disturbing to the patient than was the original preparation. These advantages are somewhat offset by a lower therapeutic activity of the newer preparation. Combinations of arsenobenzol with silver and with zinc are also used. The manufacture of arsenobenzol preparations spread during the War into the hands of a number of firms each of which has attached to the same chemical compounds trade names of their own to an extent which may be somewhat bewildering to the uninitiated.

Every arsenobenzol compound is made in batches each of which receives a distinctive mark and must pass a certain test of toxicity and of therapeutic activity before it can be issued to the public. The testing in Great Britain is carried out by the Medical Research Council. Experience has shown that, although the arsenobenzol preparations act very promptly, a number of injections in successive courses must be administered to secure eradication of syphilis and that it is advisable to supplement them by administering another metallic compound.

Arsenobenzol will not penetrate into the nerve tissue of the brain, and this limitation has led to the introduction of an arsenical preparation of another order, viz.: tryparsamide or n-phenyl glycine-amido-p-arsonic acid into the therapy of locomotor ataxy and general paresis. The results show generally that tryparsamide is valuable for this purpose.

In 1920 Sazerac and Levaditi showed that tartro-bismuthate of potassium and sodium is more powerful than mercury in destroying the spirochaetes of syphilis, and a large number of bismuth preparations have been placed on the market since it was found that it is the metal rather than the compound which matters in the therapeutic action. Generally it can be said that bismuth injections effect more towards the cure of syphilis than do mercurial and that preparations of bismuth can be used which cause less discomfort than do any mercurial.

Bismuth is useless for the cure of syphilis if given by the mouth and its injection into veins is practised very little on account of its greater toxicity when administered by this route. Bismuth is generally considered to be an adjuvant rather than a substitute for arsenobenzol treatment. It is retained in the tissues for long after a series of injections has been given, and it thus prolongs the anti-syphilitic effect after all the arsenobenzol has been excreted.

The powerful effect of the arsenobenzol and bismuth compounds on the germ of syphilis has led to a number of experiments to determine whether or not they prevent the development of syphilis after inoculation.

There is strong evidence to the effect that a few arsenobenzol injections given after contamination with syphilitic virus does protect against the disease. Kolle has produced experimental evidence tending to show that the injection of bismuth carbonate protects against infection resulting from inoculation with syphilitic virus so long as the compound remains in the muscles. Rabbits treated thus proved resistant to inoculation with syphilitic material for as long as 109 days after injection of the bismuth.

The disadvantage of injections as a method of preventing syphilis after venereal risk led Levaditi to try an arsenical compound called stovarsol or acetyl-oxyamino-phenyl arsenic acid, which is administered by the mouth. There is good evidence that the ingestion of stovarsol in suitable doses prevents infection, but considerably more work on the subject will be necessary before stovarsol can safely be given to the public as a prophylactic against syphilis.

General Paralysis of the Insane.—A great advance has been made in the treatment of a form of syphilis which is acknowledged to be the most incurable of all, namely general paralysis of the insane. This disease is one which has almost always ended fatally, defying the most intensive treatment by anti-syphilitic remedies. Its course is marked by remissions of varying length, during which the patient may appear to have recovered. It has been known for a century or more that an intercurrent infection accompanied by fever often results in a long remission, and this knowledge has led Wagner von Jauregg and his colleagues in Vienna since 1887 to inoculate patients with a variety of substances designed to make their temperatures rise. The best of all the agents has proved to be the parasite of benign tertian malaria and since its introduction in 1919 the method has been tested all over the world. The results have been very encouraging. The inoculation is by injection of malarial blood or by the bites of infected mosquitoes, and eight to twelve attacks of fever are allowed before quinine is given.

CONTROL IN THE UNITED STATES

The plan which has been developed in the United States for combating the venereal diseases is the result of many years of scientific study. As early as 1912, there were organizations dealing with the venereal diseases and with prostitution; but in 1914, it was recognized that any plan for combating venereal diseases must combine the social and legal with the medical and public health aspects and a national organization, the American Social Hygiene Association, which combined in its programme all phases of the problem of combating venereal diseases was established. The entry of the United States into the World War made it necessary for all medical and public health agencies of the country to consider what special measures could be taken to protect the armed forces of the United States from disability due to the venereal diseases. Measures were instituted, therefore, in which the medical services of the army and navy, the U.S. Public Health Service and other Federal Government agencies co-operated with the health departments of the States and cities, and with voluntary agencies such as the American Social Hygiene Association, in combating venereal diseases. This plan of control has been continued, with various modifications, and provides for the prevention and treatment of venereal diseases through three main groups of measures; viz., medical, legal and protective, and educational.

Medical Measures.—It is an essential of the plan of control of the venereal diseases that facilities which are adequate, easily available and free when necessary, be provided for diagnosis and treatment. Responsibility for providing such facilities rests primarily upon the official health authorities of the various States and cities, and these are aided by national agencies, such as the U.S. Public Health Service (official), and the American Social Hygiene Association (voluntary). In addition, many agencies, both public and private, are engaged in activities aiming through scientific research and better training of physicians and nurses to improve diagnostic and therapeutic materials and procedures. Early diagnosis and thorough treatment of all infected persons is encouraged, and an organized effort is made to discover infected persons among the families and other associates of patients. In many States, reporting, or notification, of cases of syphilis or gonorrhea is required and the law gives the health authorities the power to isolate persons who are known to be infectious and who cannot be controlled by any other means. The number of cases of syphilis notified each year approximates 200,000 and of gonorrhea 160,000. Syphilis often stands first in the total number of cases of infectious diseases notified, outranking even measles; gonococcal infections stand fourth. Studies as to the prevalence of syphilis and gonorrhea have been made in certain cities and States and these seem to show that a larger proportion of patients suffering from syphilis than of gonococcal infection place themselves under medical care. There are now in the United States approximately 650 clinics and dispensaries, where syphilis and gonorrhea are treated gratuitously or at nominal cost to the patients. In these clinics alone more than one million patients have been treated during the past eight years, and during the past year nearly 900,000 serological tests for syphilis were made by State laboratories, and 800,000 doses of arsenical preparations were dispensed by State health departments. But various studies indicate that of the patients under treatment the majority are under the care of private physicians. Thus, in New York State, private physicians were treating 61% of the cases of syphilis and 89% of the cases of gonorrhea.

Educational Measures.—Instruction of the general public in regard to venereal diseases is, like other phases of public health instruction, a duty of official health agencies, but such agencies as the American Social Hygiene Association, and its affiliated societies, co-operate in demonstrating to educational, social and religious institutions and associations in the United States the means by which scientific sex instruction can be incorporated in the

activities of schools, colleges, churches, parent-teacher associations, girls' and women's clubs, and numerous other organizations. In general, it is the aim of educational measures to promote among the general public a sound knowledge of sex problems and to integrate sex education with all forms of instruction which have for their object the development of sound moral standards as well as a knowledge of the elements of personal hygiene. Specifically, in regard to the venereal diseases, the educational programme aims to make it impossible that any persons should be infected with syphilis or gonorrhea through ignorance of the seriousness of these diseases and the means of their spread, and by making the socially sound uses of sex more appealing through right understanding of their enriching personal bearings. The methods and materials used in this educational work include lectures, motion pictures, exhibits and printed matter, and particularly the inclusion of the appropriate sex teaching in such subjects as physiology, hygiene, biology, sociology and psychology, in the schools and colleges.

Legal and Protective Measures.—These aim to reduce commercialized prostitution and other forms of promiscuous conduct by either sex, because such conduct is antisocial and such persons tend to become carriers and disseminators of venereal diseases. By providing opportunities for the wholesome use of leisure time, and through child guidance clinics, vocational adjustment bureaux, visiting teacher associations, voluntary protective agencies and women police, protective measures aim to prevent young people from forming habits and associations which may lead to promiscuity and prostitution. Legal measures involve the passage and enforcement of laws which penalize the recruitment, the exploitation and the traffic in women or girls for prostitution. They aim also to repress the activities of prostitutes and of their male customers. In addition to the passage of the necessary laws, legal measures include: the adequate training of the police, both men and women.

The responsibility for legal and protective measures rests upon the law enforcement and correctional officials and institutions of the cities, counties and States, and the Federal Government. In addition, numerous voluntary organizations, such as the American Social Hygiene Association, International Association of Policewomen, The Travellers Aid Society, and various local committees scattered about the country, aid and support the Government authorities. The duty of supervision and improvement of facilities for recreation and amusements belong to various official agencies, but many voluntary organizations, particularly the Playground and Recreation Association, are engaged in demonstrating that much can be done for the health and morals of the public, and especially of young people, by means of supervised playgrounds, community centers and through the activities of such organizations as the Boy Scouts, Girl Scouts, the Young Men's and Young Women's Christian Associations, the Knights of Columbus, Young Men's Hebrew Association, National W.C.T.U. and the National Congress of Parents and Teachers.

The U.S. army and navy have continued plans of control of the venereal diseases, similar to those of the World War period.

Conclusions as to Results.—It is too early yet to estimate the results of the public efforts which have been made to reduce and control the venereal diseases, but there are certain indications of what may reasonably be expected in the future. The death rate from syphilis, locomotor ataxia and general paralysis of the insane combined has declined 20% between the peak in 1917–25 (from 19·8 per 100,000 to 15·8 per 100,000), despite constantly increasing ability to recognize syphilis in all its manifestations. Figures from the Metropolitan Life Insurance Company show an even more marked downward trend in the death rate from syphilis. The death rate from syphilis of infants under one year of age decreased about one-third during the same period (from 105 per 100,000 years of life to 71). Both army and navy incidence rates show a large net decrease over a period of 20 years or more. It is reasonable to suppose that the combined medical, educational, legal and protective measures will in the course of one or two decades give substantial results.

VENETI (wĕn'ē-tē), name of two ancient European tribes. (1) A Celtic people in the north-west of Gallia Celtica. They were the most powerful maritime people on the Atlantic and carried on a considerable trade with Britain. Their name still remains in the town of Vannes. In the winter of 57 B.C., with some of their neighbours, they took up arms against the Romans, and in 56 were decisively defeated in a naval engagement. (Caesar, *B.G.*, iii.)

(2) The inhabitants of a district in the north of Italy called Ἐνετοί by the Greeks. It was at first included in Cisalpine Gaul, but under Augustus was the tenth region of Italy (Venetia and Histria) bounded on the west by the Athesis (Adige), or, according to others, by the Addua (Adda); on the north by the Carnic Alps; on the east by the Timavus (Timavo) or the Formio (Risano); on the south by the Adriatic Gulf. The Veneti were a peaceful people, chiefly engaged in commercial pursuits. They carried on a trade in amber, which reached them overland from the shores of the Baltic. They were famous for their skill in the training and breeding of horses. Homer (*Il.* ii. 85) speaks of the Paphlagonian *Henetoi* as breeders of "wild mules."

The first historical mention of the Veneti occurs in connection with the capture of Rome by the Gauls, whose retreat is said to have been caused by an irruption of the Veneti into their territory (Polybius ii. 18). At the request of the Romans they rendered them assistance in their wars against the Gauls north and south of the Po, and remained their loyal allies. Some time during the Second Punic War they passed under Roman rule. At first, they possessed complete autonomy in internal administration; in 89 B.C. Gnaeus Pompeius Strabo bestowed upon them the *ius Latinum;* they probably obtained the full franchise from Caesar at the same time as the Transpadane Gauls (49). Under the Empire Venetia and Istria were included in the tenth region of Italy, with capital Aquileia. Down to the time of the Antonines the country enjoyed great prosperity, which was interrupted by the invasion of the Quadi and Marcomanni and a destructive plague. It was devastated at intervals by the barbarians—by the Alamanni in A.D. 286; by the Goths under Alaric; and by the Huns under Attila (452). Under Theodoric the Great the land had rest, and in A.D. 568 was occupied by the Lombards. The most important river of Venetia was the Athesis (Adige); its chief towns were Patavium (*see* PADUA) and Aquileia (*q.v.*).

We have nearly 100 inscriptions which record the language spoken by the tribe in pre-Roman days. The full Venetic alphabet is preserved for us on several interesting dedicatory objects found at Este, which were offered to the goddess of the place called *Rehtia,* a name obviously equivalent to Latin *Rectia,* some of whose prerogatives, to judge from the long nails which were offered to her, would seem to have been those of the goddess whom Horace calls Necessitas (*Odes,* i. 35, 17).

VENETIA (*Venezia*), formerly a territorial division of Italy, lying between the Alps and the Adriatic, and stretching from the frontier of Carinthia and Istria (Austria) in the north-east to the lower Po and Lombardy in the south-west. The World War

led to the addition to Italy of a considerable territory which, though geographically Italian, had been Austrian since the fall of Napoleon; and Venetia has now been divided into three regions, which will be dealt with separately.

(1) VENETIA PROPER corresponds to the older division, with certain additions amounting to 465 sq.m. in the north, comprises the provinces of Belluno, Padua, Rovigno, Treviso, Udine, Venice, Verona and Vicenza, and has an area of 9,941 sq. miles. Pop. (1881), 2,814,173; (1901) 3,192,897; (1921) 3,999,027. Marble is quarried, especially near Verona. The chief industries are the manufacture of woollens, especially in the province of Vicenza, textiles, cottons, silks, glass, laces, tobacco, straw-plait, paper, beet sugar and hemp, the breeding of silkworms, iron-founding and working, timber-cutting and shipbuilding. At Mira is a large candle factory. Irrigation is widely spread, and large pumping stations have made extensive schemes of land reclamation possible. A large hydroelectric plant utilizes the upper waters of the Piave, and there are other plants on other rivers. The cotton plants were wrecked by the war, but now employ about 17,000. The extensive cattle breeding industry also suffered.

The territory differs much in character; the Po and other smaller rivers, notably the torrential Tagliamento, which fall into the Adriatic, terminate in a huge and continually advancing delta which extends right along the coast, and is liable to inundation. The shore lagoons are, however, rendered healthy by the ebb and flow of the tide, which is much more considerable than elsewhere in the Mediterranean. To the north of the Po, at the foot of the mountains, is a fertile territory, while the mountains themselves are not productive. A portion of the Dolomites (*q.v.*), notably the Val d'Ampezzo, with the tourist centre of Cortina d'Ampezzo, falls into the province of Belluno. To the east come the Carnic and Julian Alps, with extensive and fertile foothills, while the isolated Euganean hills near Padua are of volcanic origin. The density of population varies very considerably, that of the province of Padua being very high; while in 1911 only 53% lived in the towns, no less than 47% were spread over the countryside. There is a main railway line from Milan to Mestre (the junction for Venice) and thence to Trieste by a line near the coast, or by Treviso, Udine and Tarvisio into Austria. Another route into Austria, the Brenner, leaves the Milan-Venice line at Verona, which is connected with Bologna (and so with central and southern Italy) by a railway through Nogara, while another line runs from Verona via Mantua to Modena. A main line runs from Bologna to Ferrara, Rovigno and Padua, joining the Milan-Venice line at the last-named place.

The first inhabitants of the region found shelter in the caves of the Carso (*q.v.*), in which, as well as on various sites in the Trentino, Neolithic remains have been found; while in the Bronze age positions of natural strength were preferred, commanded by the so-called *castellieri*—stone enceintes which, to some extent, recall the early citadels of Italy and the *nuraghi* of Sardinia—many of which were occupied by Roman forts or mediaeval castles.

Under the Roman republic the district was inhabited by a variety of tribes—Celts, Veneti, Raeti, etc. Under Augustus, Venetia and Histria formed the tenth region of Augustus, the latter including the Istrian peninsula as far as the river Arsia, *i.e.*, with the exclusion of the strip along the east coast (Liburnia). It was thus far the largest of the regions of Italy, but possessed comparatively few towns; though such as there were, with their large territories, acquired considerable power and influence. The easiness of the Brenner pass and the abundance of communication with the sea led to the rise of such towns as Verona, Padua and Aquileia, and Milan only became more important than any of these when the German attacks on Italy were felt farther west.

When the Roman empire fell the towns were, many of them, destroyed by Attila. For the gradual growth of Venetian supremacy over the whole territory, and for its subsequent history, *see* VENICE, and for the eastern portion *see* FRIULI. Among the architectural features may be specially noticed the beautiful country houses of the Venetian nobility. (*See* G. K. Loukomski, *Palladio et les villas des Doges de Venise.*)

The following are the principal agricultural products for 1927:

	Acres	Tons
Wheat	744,500	467,100
Oats	38,250	25,290
Rice	9,900	13,040
Maize	781,250	555,300
Beans	439,500	25,630
Sugar beet	88,525	777,040
Hemp	14,000	5,550
Garden produce	15,250	75,540
Potatoes	59,250	258,000
Silk (cocoons)	..	15,122
Tobacco	12,975	5,914
Hay	..	3,044,600
Vines	1,555,000	367,200 Grapes 46,508,000 Wine (gal.)
Chestnuts	21,450	7,800

(2) VENETIA TRIDENTINA, consisting of the provinces of Bolzano and Trento, area 5,435 sq.m.; pop. (1921) 641,747. The greater part is mountainous. To the north-west are the Ortler (*q.v.*), and the Stelvio pass, traversed by an important road from Bormio to the Val Venosta, the upper valley of the Adige, at the head of which is the Resia (Reschen) pass, leading into the lower Engadine. (*See* SWITZERLAND.) The Wildspitz group of mountains separates this pass from the Brenner (*q.v.*), to the east of which the present frontier reaches the Vetta d'Italia and the Pizzo dei Tre Signori, and then turns sharply southwards, only beginning to run eastwards after crossing the railway from Dobbiaco to Lienz. Between it and the Brenner are the Dolomites (*q.v.*). There are important marble quarries, as yet imperfectly developed, and lead and zinc mines, notably that of Monteneve. A large amount of electric power is derived from hydroelectric plants on the Noce and the Adige.

About one-half of the total area is under forest, while three-fifths of the remainder is under cultivation, much use being made of irrigation for pastures, and also for maize. Vegetables and fruit are grown in the sheltered districts of Merano and Bolzano. The production of silkworms is less important than about the middle of the 19th century, and the spinneries have also decreased. The only main railway line is the Brenner, which at Trento has a branch for Bassano, at Bolzano for Merano and Malles, at Ponte all' Isarco for Selva, and at Fortezza (formerly Franzensfeste) for Dobbiaco and S. Candido (the Italian frontier point) and thence to Lienz and Villach.

The following are the principal agricultural products for 1927:

	Acres	Tons
Rye	34,500	17,900
Barley	17,250	8,140
Oats	15,750	7,060
Garden produce	6,550	38,820
Potatoes	26,500	137,800
Hay	..	852,600
Vines	84,750	63,000 Grapes 9,856,000 Wine (gal.)
Fruit (various)	..	48,605

(3) VENETIA JULIA (VENEZIA GIULIA), a territorial division of northern Italy, consisting of the provinces of Gorizia, Pola and Trieste (to which the detached provinces of Fiume and Zara are also aggregated). Pop. (1921) 930,108; area 3,389 sq. miles. The coast line to the east of the Tagliamento is fringed by alluvial deposits and lagoons, mostly of very modern formation, for as late as the 5th century Aquileia was a great seaport. The harbour of Grado is unimportant, but to the east is the shipbuilding yard of Monfalcone, and beyond that the great port of Trieste; while the Istrian peninsula has several small harbours: Capodistria, Parenzo and Rovigno, besides Pola, formerly the chief naval port of Austria. Fiume, at the head of the gulf of that name, is another fine harbour. The province of Gorizia, except towards the south-west, where it unites with the lowlands of Friuli (*q.v.*), is surrounded by mountains, and most of its area is occupied by mountains and hills. From the Julian Alps, which traverse the province in the north, the country descends in suc-

cessive terraces towards the sea. The principal peaks in the Julian Alps are the Monte Canin (8,469 ft.), the Monte Nero (7,367 ft.), the Matajur (5,386 ft.), and the highest peak in the whole range, the Tricorno or Triglav (9,394 ft.). The southern part of the province and that of Trieste belong to the Carso (*q.v.*), in which the caves of Postumia and San Canziano are situated. The principal river of the district is the Isonzo, which rises in the Tricorno, and pursues a strange zigzag course for a distance of 78 m. before it reaches the Adriatic. It is navigable only in its lowest section, where it takes the name of the Sdobba. Its principal affluents are the Idria, the Vipacco and the Torre, with its tributary the Judrio. Of special interest is the Timavus or Timavo, which appears near Duino, and after a very short course flows into the Gulf of Trieste. To the east is the desolate limestone plateau of the Carso (*q.v.*). For the province of Pola, *see* ISTRIA.

Agriculture, and especially viticulture, is the principal occupation of the population, and the vine is here planted not only in regular vineyards, but is introduced in long lines through the ordinary fields and carried up the hills in terraces locally called *ronchi*. The rearing of the silk-worm, especially in the lowlands, constituted another great source of revenue, but the quantity raised in 1927 was very small.

Gorizia (Görz) first appears distinctly in history about the close of the 10th century, as part of a district bestowed by the emperor Otto III. on John, patriarch of Aquileia. In the 11th century it became the seat of the Eppenstein family, who frequently bore the title of counts of Gorizia; and in the beginning of the 12th century the countship passed from them to the Lurngau family, which continued to exist till the year 1500, and acquired possessions in Tirol, Carinthia, Friuli and Styria. On the death of Count Leonhard (April 12, 1500) the fief reverted to the house of Habsburg. The countship of Gradisca was united with it in 1754. The province was occupied by the French in 1809, but reverted again to Austria in 1815. It formed a district of the administrative province of Trieste until 1861, when it became a separate crownland. In 1918 it passed to Italy.

The following are the principal agricultural products for 1927:—

	Acres	Tons
Barley	16,250	7,850
Garden produce	10,325	25,200
Potatoes	37,500	56,500
Silk (cocoons)	..	98
Hay	..	313,200
Fruit, various	..	15,565
Vines	79,000	61,000 Grapes 8,228,000 Wine (gals.)

The railway system is well developed, mainly centring on Trieste and Gorizia. Besides the line from Trieste by Monfalcone to Treviso, which is the main line of communication with the rest of Italy, there is a line from Monfalcone to Gorizia and thence up the Isonzo valley to the frontier at Piedicolle (thence to Villach and Klagenfurt), and a line direct from Trieste to Gorizia. Trieste also has lines to Postumia, the frontier station, and thence to Lubiana (with branches to Pola and Fiume, both running through the interior of Istria) and along the coast to Capodistria, Pirano and Parenzo. Shipbuilding is carried on at Trieste, Pola and Monfalcone: Trieste (*q.v.*) is also a great port and centre of industry, with many factories, notably oil mills and refineries, jute factories, rice mills, etc., while at Monfalcone soda and other chemicals are made; at Cervignano, starch, at Capodistria, Pirano and Rovigno, preserved foods; tobacco at Rovigno, liqueurs at Rovigno and Parenzo; at Pirano and Capodistria there are large salt works. Friuli produced, in 1926, 2,367 tons of lead and 36,248 of zinc. The district of Trieste produced 186,980 tons of coal of an inferior quality. Istria produced 85,000 tons of bauxite, which were treated at Mestre for the extraction of aluminium. The mercury mines of Idria produced 600 tons of cinnabar (1,000 workmen) in 1924. The fishing industry of Istria is important, and much of the canning is done at Trieste.

See A. Tamaro, *La Vénétie Julienne et la Dalmatie* (3 vols., 1919). (T. A.)

VENETIC LANGUAGE. We have nearly 100 inscriptions which record the language spoken by the Veneti (*q.v.*) in pre-Roman days. Others have also come to light at Verona and Padua, and at different points along the great north and south route of the Brenner Pass, especially at Bolzano; and there are a few more scanty and scattered monuments in the Carinthian Alps now preserved chiefly in the museums at Klagenfurt and Vienna. The alphabet of the inscriptions, in all its varieties, is probably either derived from or at least influenced by some form of the Etruscan alphabet, since it not merely coincides with that alphabet in several characteristic signs, such as the use of the compound symbol *vh* () with the value of *f*, but lacks the symbols for the mediae BDG. These, or the sounds which had descended from them in Venetic, were represented by using symbols which in the Western Greek alphabets denoted kindred sounds;  *z* where we should expect *d* (*zoto*, "he gave"), Φ*φ* where we should expect *b* (*φohιιος*, "Boius"),  (*i.e.*, χ) where we should expect *g* (*·ε·χo*, "ego"). But though we find the symbols in positions where they correspond to the mediae in kindred languages, it is uncertain what was the precise variety of sound which they denoted. Thus, for example, Venetic *·ε·χo* is certainly equivalent to the Latin *ego*, but we cannot be certain that the sound of the two words was precisely the same. The symbol for *θ* is not used to denote *d* (since that is represented by *z*). In the inscriptions of Padua and Verona the sign is **O** and seems there to denote some variety of sound closely akin to *t*; the word which at Padua and Verona is written *·ε·kupeθari·s·*, probably meaning "charioteer," appears as *ecupetaris* in Latin alphabet in an inscription published by Elia Lattes ("Iscrizioni Inedite Venete ed Etrusche," *Rendiconti del R. 1st Lomb. di Sc. e Lett.*, Serie II. vol. xxxiv., 1901). The full Venetic alphabet at its best period is preserved for us on several dedicatory objects found at Este, which were offered to the goddess of the place called *Rehtia*, a name obviously equivalent to Latin *Rectia*. The offerings in question are thin bronze plates of whose surface the greater part is covered by alphabetic signs, with an inscription stating that the worshipper makes an offering of the plate to the Goddess. These plates provide enough material to place the alphabet of Este beyond all doubt. It is written from right to left, and the alternate lines curl round so that the letters proceed in the opposite direction and stand with their feet turned towards those in the preceding line. This characteristic, technically known as "serpentine boustrophedon," with the sign for *h* (), points to some connection with the alphabets of the East Italic ("Sabellic") inscriptions (*see* SABELLIC).

The alphabet shows some marked differences from the western Greek alphabet used in Elis. The language belongs to the Indo-European group, but the forms with which the inscriptions of Este supply us are somewhat limited in number. The typical beginning for a dedication is *meχo . . . zona· s· to sahnateh rehtiiah, i.e.*, "me dedit Rectiae Sanatrici," "so and so gave me to the Healing Goddess Rectia"; and sometimes the form of the verb is simply *z·o·to*. The correspondence of these two forms with the Greek middle aorist of the verb (ἔ-δοτο), and with the Latin *donare* is obvious. One inscription of special linguistic interest is the artist's inscription of a vase of the 6th century B.C. found at Padua—

voθo kluθeari·s· vhaχ·s·to,

where the first name appears to be identical with the Latin *Ortho* and also seems to explain its aspirate, and the last word of the inscription appears to be the Venetic equivalent of the Latin *fecit*, but to be in the middle voice without any argument. If this interpretation be correct—and the use of ἐποιησε by Greek artists commends it strongly—the form illustrates the character of the language as intermediate between Greek and Latin.

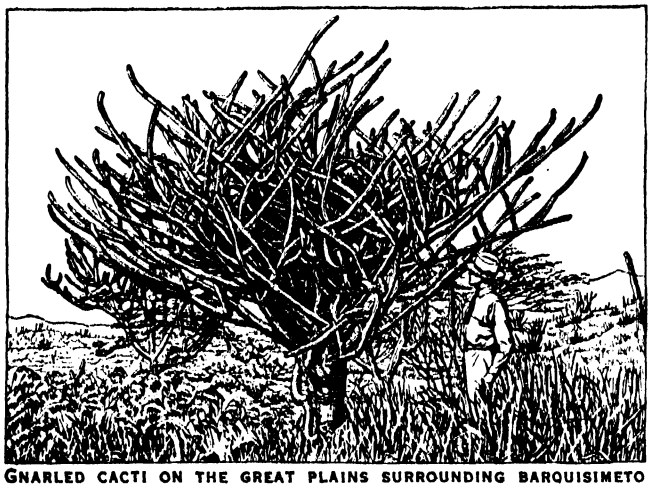
VENETTE, JEAN DE (*c.* 1307–*c.* 1370), French chronicler, born at Venette, near Compiègne, became prior of the Carmelite convent in the Place Maubert, Paris, in 1339, and was provincial of France from 1341 to 1366. In 1368 he was still living, but probably died within a year or two of that date. His Latin Chronicle, covering the years 1340 to 1368, was published by Achery (*Spicilegium*, vol. iii.) Jean de Venette was a child of the people, and his sympathies were entirely with the peasants. His point of view is thus directly opposed to that of Froissart. Jean de Venette also wrote a long French poem, *La Vie des trois Maries*, about 1347.

See Lacurne de Sainte-Palaye in *Mémoires de l'Académie*, vols. viii. and xiii.; Géraud and Déprez in *Mélanges de l'école de Rome* (1899), vol. xix.; and A. Molinier, *Les Sources de l'histoire de France* (1904), tome iv.

VENEZUELA, a republic of South America, on the coast of the Caribbean, lying between Brazil and British Guiana on the east and south, and Colombia on the west. The name means "little Venice," and is a modification of the name of Venecia (Venice), originally bestowed by Alonzo de Ojeda in 1499 on an Indian village, composed of pile dwellings on the shores of the Gulf of Maracaibo, which was called by him the Gulf of Venecia. Its area is 398,594 square miles. Pop. (1926) 3,026,878. The population of Caracas, the capital, in 1920 was 92,212; in 1926 it was 135,253. That of Maracaibo, the next largest city, in 1920 was 46,706, and in 1926 it was 60,000 (estimated by some to be as high as 100,000, due to the influx of many oil workers). That of Valencia was 29,466 in 1920, and 45,523 in 1926.



Topography.—The surface of Venezuela is broken into three irregular divisions by its mountain systems: (1) the mountainous area of the north-west and north; (2) the Orinoco basin with the *llanos* on its northern border and great forested areas in the south and south-west; and (3) the Guiana highlands. A branch of the eastern chain of the Andes enters Venezuela in the west about 7° N. lat., and under the name of the Sierra Nevada de Mérida proceeds north-eastwards towards Trieste Gulf. This branch is of parallel chains enclosing elevated valleys, in one of which lies the town of Mérida (5,410 ft.), overlooked by the highest summit of the chain (Picacho de la Sierra, 15,420 ft.). The sierra contains the water-parting between the basin of the Orinoco and those of the small rivers on the north-west. Hence it may be considered to terminate where the Río Cojedes, which drains the elevated valley in which Barquisimeto stands, after rising on its western slopes, flows eastwards into the basin of the Orinoco. Beyond the Cojedes begin two parallel ranges, the Maritime Andes of Venezuela, which stretch east and west along the coast. The valley between these two ranges is the most densely peopled part of Venezuela. Behind the bay between Cape Codera and Cumaná there is an interruption in the Maritime Andes, the *llanos* fronting on the coast for over 100 m.; but both ranges reappear between Cumaná and the Gulf of Paria. West of the Maritime Andes low ranges (3,500–5,000 ft.) trend northwards from the end of the Sierra de Mérida towards the coast on the east side of the lake of Maracaibo, while the region on the west of that lake consists of lagoon-studded lowlands. East and south of the Sierra de Mérida and the Maritime Andes the region consists of two portions—a vast mountainous area, densely wooded, in the south-east and south, and level plains in the north-west between the Orinoco and the Apure and the mountains. The latter is known as the *llanos* of the Orinoco, a vast grass-covered plain with scattered islands of wood. Along the Brazilian frontier and about the sources of the Orinoco tributaries on the eastern slopes of the Andes there are extensive forests, sometimes broken with grassy *campos*. The general elevation of the *llanos* varies from about 375 to 400 ft., rising to 600–800 ft. around its immediate margins. So uniform is the level over a great part that in the rainy season hundreds of square miles are submerged, and the country is covered with connecting channels. North of the middle Orinoco, however, a series of low gravel capped mesas break the monotony and form the divide between the water of the Orinoco and the streams that flow northward into the Caribbean. The lower basin of the Orinoco is contracted between the Guiana highlands and the northern uplands, and its tributaries come in more nearly at right angles, showing that the margins of the actual valley are nearer and higher. About 62° 30′ W. long. the river reaches what may be thought sea-level; from this point numerous channels cross the silted-up delta-plain to the sea. This region, together with that of the Guiana frontier, is heavily forested. In the extreme south (territory of Amazonas) and south-east the surface again rises into mountain ranges, which include the Parima and Pacaraima sierras on and adjacent to the Brazilian frontier, with short spurs reaching northward toward the Orinoco, such as the Mapichi, Maraguaca, Maigualida, Matos, Rincote and Usupamo. This region belongs to the drainage basin of the Orinoco, and rivers of large volume flow between these spurs. Some of the culminating points in these ranges are the Cerros Yaparana (7,175 ft.) and Duida (8,120 ft.) in the Parima sierras near the upper Orinoco, the Sierra de Maraguaca (8,228 ft.), and the flat-topped Mt. Roraima (8,530 ft.) in the Pacaraima sierras on the boundary line with Brazil and British Guiana. Near the Orinoco the general elevation drops to about 1,500 feet. This region is densely forested, and is inhabited only by Indians.

Probably not less than four-fifths of the territory of Venezuela belong to the drainage basin of the Orinoco (*q.v.*). The Orinoco is supposed to have 436 tributaries, of which, among the largest, the Caroni-Paragua, Aro, Caura, Cuchivero, Suapure, Sipapo and Ventuari have their sources in the Guiana highlands; the Suata, Manapere and Guaritico in the northern sierras; and the Apure, Uricana, Arauca, Capanaparo, Meta, Vichada and Guaviare (the last three being Colombian rivers) in the *llanos* and Andes. The Apure receives two large tributaries from the northern sierras—the Guárico and Portuguesa. Apart from these, the rivers of Venezuela are small and, except those of the Maracaibo basin, are rarely navigable. The larger are the Guanipa and Guarapiche, which flow eastwards to the Gulf of Paria; the Aragua, Unare and Tuy, which flow to the Caribbean coast east of Caracas; the Yaracui, Aroa and Tocuyo to the same coast west of Caracas; and the Motatán, Chama, Escalante, Catatumbo, Apóan and Palmar, which discharge into Lake Maracaibo. The hydrography of the region last mentioned, where the lowlands are flat and the rainfall heavy, is extremely complicated owing to the great number of small rivers and of lakes on or near the lower river courses. The deep lower courses of these streams and the lakes were once part of the great lake itself, which is being slowly filled by silt. The lakes of Venezuela are said to number 204. The largest are the Maracaibo (*q.v.*); the Zulia, with an area of 290 sq.m., a short distance south of Maracaibo among a large number of lakes, lagoons and swamps; Valencia, near the city of that name, in the Maritime Andes, about 1,350 ft. above sea-level, with an area of 216 sq.m.; Laguneta, in the State of Zulia; and Tacarigua, a coastal lagoon in the State of Miranda.

The coast outline of Venezuela is indented. The larger indentations are the Gulf of Maracaibo, or Venezuela, which extends inland through the Lake of Maracaibo, with which it is connected by a comparatively narrow and shallow channel, and is formed by the peninsulas of Goajira and Paraguaná; the Gulf of Paria, between the peninsula of that name and the island of Trinidad; the Gulf of Coro, opening into the Gulf of Maracaibo; the Gulf of Cariaco, between the peninsula of Araya and the mainland; the Golfo Triste, on the east coast of the State of Lara; and the small Gulf of Santa Fé, on the northern coast of the State of Sucre. Besides these there are small sheltered anchorages formed by islands and reefs like that of Puerto Cabello, and estuaries and open roadsteads, like those of La Guaira and Carúpano, which serve important ports. There are 71 islands, with an aggregate area of 14,633 sq.m., according to official calculations. The largest of these is the island of Margarita, north of the peninsula of Araya near which is the island of Tortuga and several groups of islets, generally uninhabited. (A. J. L.)

Geology.—Venezuela may be divided into three principal physiographic regions: (1) The Venezuela or Guiana highlands which lie south of the Orinoco and consist of a great mass of Archaean granite, gneiss and other crystalline rocks and over-

lying beds of sandstone and shale; (2) the llanos, almost treeless plains between the Orinoco and the Andes, which are in large part covered with Tertiary and Quaternary deposits of gravel, sand and clay loam; (3) the mountain ranges—the Cordillera of Mérida and the Coast or Caribbean range—which consist of cores of granite and schist flanked by sedimentary beds folded in anticlinal structure. Minor physiographic units are the delta region on the east coast, at the mouths of the Orinoco and other rivers; and the basin of Lake Maracaibo, a large structural depression. The oldest rocks in northern South America form the basement complex of the Guiana highlands. In Venezuela these rocks consist chiefly of the granites and gneisses of the southern massif and the crystalline schists which form the axis of the Cordillera and the Caribbean chain. Upon this basement lie beds of sandstone and shale, most of them of early Cretaceous age and locally much altered, which at some places are overlain by Pleistocene or Recent deposits and into which are intruded dikes and masses of basalt and other igneous rocks.

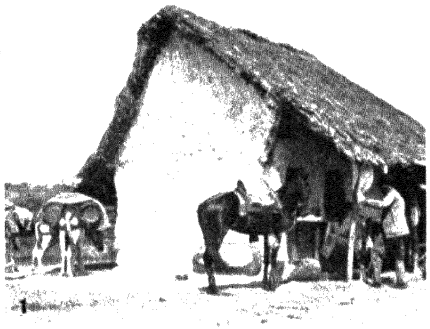
GNARLED CACTI ON THE GREAT PLAINS SURROUNDING BARQUISIMETO

The range of the Andes that enters Venezuela from Colombia continues to the N.E. with gradually diminishing elevation and merges into the Coast range. In Venezuela these mountains reach their greatest heights in the snow-capped peaks of La Columna (16,410 ft.), Monte Humboldt (16,212 ft.) and La Concha (16,146 ft). The granitic core of the Venezuelan Andes is cut by many intrusive bodies of pegmatite, basalt and quartz, and the sedimentary beds of the range, most of which are of Cretaceous and Tertiary age, are intricately folded. Cretaceous rocks crop out in places along each side of the Andes in Venezuela and along the south side of the Coast range.

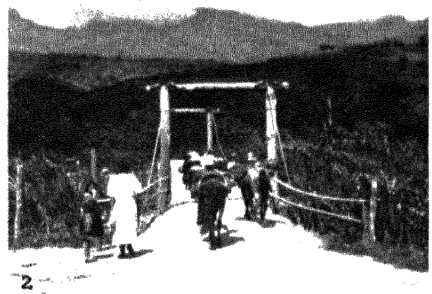
Around Lake Maracaibo, which lies in a basin that is to some extent outlined by faults, there is a surface deposit of Quaternary alluvium, which is underlain by folded Tertiary beds. Petroleum seeps from springs around the lake and is obtained in large quantity from wells sunk to Cretaceous and Tertiary beds. Recent terrestrial deposits consisting of unconsolidated sand, gravel, clay and alluvium cover a large part of the lower regions in Venezuela. In the delta region at the mouths of the Orinoco these deposits are thick and are accumulating rapidly. Gold has been mined in the eastern part of the Guiana highlands near Callao. Most of it occurs in quartz veins near basaltic intrusive rock. Iron ore is mined in the Sierra Imataca south of the Orinoco. Copper is mined near Aroa and San Felipe, in the State of Yaracuy. Coal is found in Tertiary beds in the region north of the Orinoco, but it can be mined profitably at only a few places. The output of petroleum is shown in the following table:

	Barrels		*Barrels*
1917	119,692	1923	4,003,662
1918	317,467	1924	9,041,999
1919	424,735	1925	19,687,406
1920	457,010	1926	37,226,019
1921	1,433,656	1927	63,391,764
1922	2,201,114	1928 (est.)	100,000,000

Venezuela ranked third (*see* p. 52) among the petroleum producing countries of the world in 1927 and second in 1928 (*see* p. 52). (G. McL. Wo.)



Climate.—The climate of Venezuela is everywhere tropical except where modified by altitude. In the Maritime Andes at and above the altitude of Caracas it is semi-tropical, and in the still higher regions of western Venezuela it approaches the mild temperate. On the coast and the northern slopes of the Maritime Andes the tropical heat is greatly modified by the trade-winds. At La Guaira the mean temperature for the year is 81° F, at Caracas (3,025 ft.) it is 70°, at Cumaná it is 83°, at Valencia 76°, Coro 82°, Barquisimeto 78°, Yaritagua 80·6°, Mérida 61°, Trujillo 72° and Maracaibo 81°. South of the sierras, the climate is much drier and hotter. The low night temperatures in these regions lower the mean annual temperatures. At Calabozo, for instance, the mean is about 88°, though the maximum in summer is not far from 100°. The lowest temperatures recorded are those of Mucuchíes, in the State of Mérida, where the maximum is 68°, the minimum 43° and the mean 56°. The year is divided into two seasons, the dry and wet, the latter occurring from April to October, when the temperature is also the highest. On the *llanos* the dry season destroys the pasturage, dries up streams and compels animals of semi-aquatic habits to aestivate. At Caracas the annual rainfall ranged from 602 to 863 mm. between 1894 and 1902. In general the climate of Venezuela is healthful. The sanitary condition is generally bad, and many forms of disease prevail that are not due to the climate.



Fauna.—The fauna and flora of Venezuela are similar to those of the neighbouring regions of Guiana, Brazil and Colombia, the open *llanos* of the Orinoco being something of a neutral district between the great forested regions on the east, south and west. Among the animals indigenous to the country are seven species of the cat family, including the puma, the jaguar and the ocelot; the wild dog (*Canis azarae*); representatives of the marten family, including two species of *Galictis,* two of the otter (*Lutra brasiliensis* and *L. pteronura*) and one of the skunk; two species of bear (*Ursus ornatus* and *U. nasutus*); and the "kinkajou." There are six species of monkey corresponding to those of Guiana and the Amazon valley, the sloth and ant-eater, 12 known genera of rodents, including many species of *Mures,* the cavy, the capybara, the paca, the nutria, the agouti, the tree porcupine, *Loncheres cristata, Echimys cayen* and the Brazilian hare. Among the pachyderms the tapir is found in the forests of the Orinoco. There are two species of the peccary, *Dicotyles torquatus* and *D. labiatus.* There are also two species of deer, *Cervus rufus* and *C. simplicornis.* There are three species of opossum. On the coast and in the Orinoco there may be found the manatee and the dolphin. The Reptilia include 11 species of the crocodile, alligator and lizard, including the savage *jacaré* of the Amazon, several species of the turtle, four species of batrachians, and 29 species of serpents, including the striped rattlesnake (*Crotalus durissus*), *Lachesis mutus,* and a rather rare species of *Cophias.* Among the non-venomous species, the commonest are the boa-constrictor, the anaconda (*Eunectes murinus*) and the *Coluber variabilis.* Bird life is represented chiefly by migratory species, particularly of genera that inhabit the shores of streams and lagoons. In the *garzeros* of Venezuela are to be found nearly every kind of heron, crane, stork and ibis, together with an incredible number of Grallatores. Ducks are also numerous, including a small bird called the *guiriri,* in imitation of its cry. Birds of prey are numerous. One species, the guacharo (*Steatornis caripensis*), or oil-bird, is commonly said to occur only in Venezuela, though it is found in Colombia and Ecuador also. They live in caves, especially in Caripe, and are caught for the oil extracted from them. The bell-bird (*Chasmorhynchus carunculatus*) is common in the forests of the Orinoco. In the 14 orders

INDUSTRIAL SCENES IN VENEZUELA

1. Vaqueros rounding up a herd of cattle. The broad, grassy plains furnish excellent grazing for stock
2. Primitive method of ploughing in Venezuela. This farm is high up in the Andes mountains
3. An Andino taking his produce to market
4. Unloading freight at Maracaibo. A large part of the goods consumed in eastern Colombia goes through this port
5. A coconut harvest awaiting shipment
6. Waterfront at Maracaibo showing shipping activity
7. A milkman of Caracas, capital of Venezuela, delivering milk
8. Water carriers of the Llanos. The scarcity of water has made its sale an established trade
9. Burro train in Merida. In this mountainous region much of the freight is carried on burros
10. A street vendor selling shoes in the old quarters of Caracas
11. Market for the sale of fruit and flowers in San Jacinto. The house of Simon Bolivar, the liberator of South America, may be seen in the background
12. Water carriers near Barquisimeto carrying bladders of water strapped to the sides of their burros to sell on the arid plains south of the city

of insects there are no fewer than 98 families. There are eight families of Coleoptera, six of Orthoptera, 23 of Hymenoptera, 14 of Lepidoptera and seven of Diptera. Locusts are numerous in the interior. Molluscs, including the pearl oyster, are common on the coasts and in the fresh-water streams and lakes.

Flora.—The flora covers a wide range because of the vertical climatic zones. The coastal zone and lower slopes of all the mountains, including the lower Orinoco region and the Maracaibo basin, are clothed with a typical tropical vegetation. There is no seasonal interruption in vegetation. The tropical vegetation extends to an altitude of about 1,300 ft., above which it may be classed as semi-tropical up to about 3,500 ft., and temperate up to 7,200 ft., above which the vegetation is Alpine. Palms grow everywhere; among them the coco-nut palm (*Cocos nucifera*) is the most prominent. There are some exotics in this zone, like the mango, which thrive so well that they are thought to be indigenous. The cacao is at its best in the humid forests and is cultivated in the rich alluvial valleys, and the banana thrives everywhere, as well as the exotic orange and lemon. On the mountain slopes orchids grow in profusion. Sugar-cane is cultivated in the alluvial valleys and coffee on their slopes up to a height of about 7,000 feet. Among the many tropical fruits to be found in this region are guavas, mangoes, cashews, bread-fruit, aguacates, papayas, zapotes and granadillas. In the next zone are grown many cereals (including rice), beans, tobacco, sugar-cane, peaches, apricots, quinces and strawberries. The *llanos* have some distinguishing characteristics. They are extensive grassy plains, the lowest being the bed of an ancient inland lake about which is a broad terrace (*mesa*), the talus perhaps of the ancient encircling highlands. The lower level has extensive lagoons and swampy areas and suffers less from the long periodical drought. Its wild grasses are luxuriant and a shrubby growth is found along its streams. The decline in stock-breeding has resulted in a considerable growth of trees and chaparral over the greater part of the plain.

One of the most remarkable palms is the "moriche" (*Mauritia flexuosa*). The fruit is edible and its juice is made into beer; the sap of the tree is made into wine, and its pith into bread; the leaves furnish an excellent thatch, and the fibre extracted from their midribs is used for fish lines, cordage, hammocks, nets, etc., and the wood is hard and makes good building material. The fruit of the *Guilielma* is also widely used for food among the natives. Among other forest trees of economic importance are the silk-cotton tree (*Bombax ceiba*), the *palo de vaca*, or cow-tree (*Brosimum galactodendron*), whose sap resembles milk and is used for that purpose, the *Inga saman*, the *Hevea guayanensis*, celebrated in the production of rubber, and the *Attalea speciosa*, distinguished for the length of its leaves.

The principal economic plants of the country are cacao, coffee, cassava (manioc), called "mandioca" in Brazil, Indian corn, beans, sweet-potatoes, taro, sugar-cane, cotton and tobacco. Of these coffee and sugar-cane were introduced by Europeans.

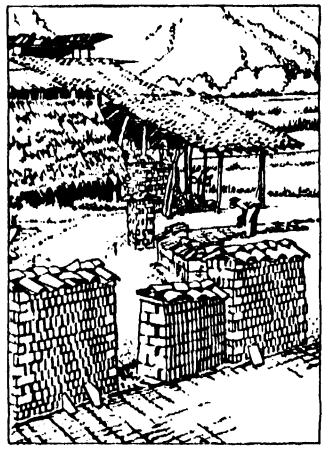
Population.—The population of Venezuela consists of a small percentage of whites of European descent, chiefly Spaniards, a few tribes and settlements of Indians, largely of the Arawak and Carib families, and a large percentage of *mestizos*, or mixed bloods. There is a considerable admixture of African blood.

Territorial Divisions.—Venezuela's constitution of 1925 declared that the republic was composed of 20 States, two territories, a Federal district and certain islands in the sea of the Antilles. It provided that the Federal District was to be organized by a special law and should be composed of the city of Caracas with the neighbouring parishes.

The States and territories, with their capitals, are now as follows: Federal District (Caracas); Anzoátegui (Barcelona); Apure (San Fernando de Apure); Aragua (Maracay); Bolívar (Ciudad Bolívar); Carabobo (Valencia); Cojedes (San Carlos); Falcón (Coro); Guárico (Calabozo); Lara (Barquisimeto); Mérida (Mérida); Miranda (Ocumare); Monagas (Maturín); Nueva Esparta (La Asunción); Portuguesa (Guanare); Sucre (Cumaná); Táchira (San Cristóbal); Trujillo (Trujillo); Yaracuy (San Felipe); Zamora (Barinas); Zulia (Maracaibo), with the following territories: Amazonas (San Fernando de Atabapo); Delta-Amacuro (Tucupita).

Communications and Commerce.—There has been no great development of railway construction in Venezuela, partly on account of political insecurity and partly because of the backward industrial state of the country. In 1924 there were 13 railway lines with a mileage of about 660 m., including the short lines. The best known of the Venezuelan railways is the short line from La Guaira to Caracas (22¾ m.), which scales the steep sides of the mountain behind La Guaira and reaches 3,135 ft. before arriving at Caracas. It is now electrically operated. It is a British enterprise, and is one of the few railways in Venezuela that pay a dividend. The Puerto Cabello and Valencia line (34 m.) is another British undertaking and carries a good traffic. Wireless communication with the outside world is maintained through the stations at Caracas, Maracaibo, Puerto Cabello and several other places.

LOADING LLANOS CATTLE INTO A RIVER BOAT AT CIUDAD BOLÍVAR, BY MEANS OF A CHUTE WHICH LEADS TO THE LOWER DECK OF THE BOAT



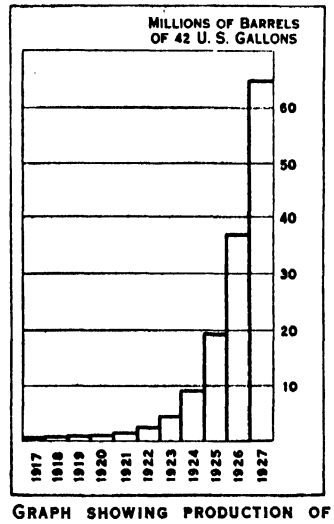
The government is devoting large sums to the construction of motor roads. According to latest reports some 3,700 m. have been opened. The greatest of these is the transandine highway from Caracas to Táchira on the Colombian frontier, 804 miles.

In domestic steamship lines it has relatively little to show. A regular service is maintained on Lake Maracaibo, one on Lake Valencia, and another on the Orinoco, Apure and Portuguesa rivers, starting from Ciudad Bolívar. That on Lake Maracaibo has assumed new importance since the development of the oil fields about the lake.

The coast of Venezuela has an aggregate length of 1,876 m., and there are 32 ports, large and small, not including those of Lakes Maracaibo and Tacarigua and the Orinoco. The majority have only a limited commerce. The first-class ports are La Guaira, Puerto Cabello, Ciudad Bolívar, Maracaibo and Carúpano, and the second-class are Sucre, Juan Griego, Guiria, Caño Colorado, Guanta, Tucacas, La Vela and Porlamar. The imports include hardware and building materials, earthenware, glassware, furniture, drugs and medicines, wines, foodstuffs and coal. The coasting trade is largely made up of products destined for exportation, or imports trans-shipped from the first-class ports to the smaller ones which have no direct relations with foreign countries. The Orinoco trade is carried on largely through Port of Spain, Trinidad, where merchandise and produce is transferred between river boats and foreign ocean-going steamers.

Industry and Commerce.—The principal industries are agricultural and pastoral. Both have suffered heavily from military operations and disturbed political conditions, but peace has now been consolidated for many years and both have progressed. Much the greater part of the Republic is fertile and adapted to cultivation. Irrigation, which has not been much used, is needed in some parts of the country and is being provided for. In other parts, as in the valleys and on the northern slopes of the Maritime Andes, the rainfall is sufficiently well distributed to meet most requirements. The long dry season of the *llanos* and surrounding slopes, which have not as yet been devoted to cultivation, will require a different system of agriculture with systematic irrigation. In colonial times the *llanos* were covered with immense herds of cattle and horses and were inhabited by a race of expert horsemen, the *llaneros*. Both sides in the War of Independence drew upon these herds, and the *llaneros* were among the bravest in both armies. The end of the war found the *llanos* almost deserted. Successive civil wars prevented their recovery, and these plains, which ought to be one of the chief sources of meat supply for the country, are comparatively destitute of stock, and

the only source of revenue from this industry is the small number of animals shipped to the West Indies. The breeding of goats and swine is an important industry in some regions. Other industries of the colonial period were the cultivation of indigo and tobacco. The former has nearly disappeared, but the latter is still an important product. The best known tobacco-producing localities are Capadare, Yaritagua, Mérida, Cumanacoa, Guanape, Guaribe and Barinas. No effort is made to improve the Venezuelan product, a part of which is exported to Cuba for cigar-making. The principal agricultural products are coffee, cacao, sugar, Indian corn and beans. Coffee was introduced from Martinique in 1784 and its exportation began five years later. A recent estimate (1926) gives the number of coffee trees in Venezuela as 250,000,000 belonging to 25,000 estates, occupying some 200,000 ac.; the average annual yield is from 85 million to 100 million pounds. Cacao (*Theobroma cacao*) is an indigenous product and is extensively cultivated on the Caribbean slopes. It requires a high temperature (about 80° F), freedom from strong winds, rich soil and a high degree of humidity for the best development of the tree. The tree has an average height of 12–13 ft., begins bearing five years after planting, the yield being from 490 to 600 lb. per ac. of 100 trees. There are two grades of Venezuelan cacao—the *criollo* or native, and the *trinitario*, or Trinidad, the first being superior in quality. The best cacao comes from Caracas and is marketed under that name. The average production in Venezuela is about 50 million pounds per year, most of which is exported, the larger part going to the United States and France. Sugar-cane is not indigenous, but it is cultivated with success in the lowlands of Zulia, and on the coast. Its principal product is "papelón," or brown sugar, which is put on the market in the shape of small cylindrical and cubical masses of 1¾ to 3½ lb. weight. This quality is the only one which is consumed in the country, with the exception of a comparatively small quantity of refined sugar. The annual output is about 60,000 tons. Cotton was produced in several places in colonial times, but the output has now declined to a few thousand pounds. The plant is indigenous and grows well, but, unlike cacao, it requires much manual labour in its cultivation and picking and does not seem to be favoured by the planters. Indian corn is widely grown and provides the staple food of the people. Beans also are a common food, and are universally produced. Wheat was introduced by the Spaniards immediately after their occupation of Venezuela, and is grown in the elevated districts of Aragua and the western states, but the production does not exceed home consumption. Rice is a common article of food, but not enough is grown to supply the local demand. Other agricultural products are sweet-potatoes, cassava (manioc), yuca, yams, white potatoes, maguey, okra, peanuts, peas, all the vegetables of the hot and temperate climates, oranges, lemons, limes, bananas, plantains, figs, grapes, coco-nuts, pine-apples, strawberries, plums, guavas, breadfruit, mangoes and many others. There are also many wild fruits like those of the cactus and various palms, and these are largely consumed. The forest products, whose collection and preparation form regular industries, are rubber (called *caucho* or *goma*), tonka beans, vanilla, copaiba, sarsaparilla, divi-divi, dye-woods, cabinet-woods and fibres. The rubber forests are on the Orinoco and its tributaries.



A BRICKYARD OF VENEZUELA

Mining.—The principal minerals are petroleum, gold, copper, iron, sulphur, coal and asphalt. Oil seepages were known in Venezuela before the discovery of America, particularly in the Maracaibo Basin and in the delta of the Orinoco. Deposits of asphalt, associated with these seepages, were exploited for many years, the great asphalt lake of Bermudez, like that on the adjacent British island of Trinidad, yielding large quantities for shipment. About 1912 attention was attracted to the country as a possible source of oil, and several large companies began the drilling of wells. Disturbed political conditions in Mexico probably hastened activities in Venezuela. Starting in earnest in 1920, the development came rapidly, centring on the shores of Lake Maracaibo, where, by 1924, some 5,600,000 barrels of oil were being produced. Unusually large returns were secured from some wells, resulting in a veritable oil boom, and by 1927 Venezuela had taken third place among the nations of the world in the production of petroleum. In that year there were 20 companies operating, with a total of 200 wells and a production of 64,436,926 barrels. In 1928, Venezuela surpassed Russia in its output and ranked second only to the United States. Almost all the actual development is confined to the Maracaibo Basin, about whose margin numerous pools have been located. The most important fields which are situated here are the Mene, Mene Grande, La Rosa, and Ambrosio; the La Paz, the Río Palmar and the Concepción; the Río de Oro and the Tarra fields; and the newer Falcón field. In eastern Venezuela is located the Guanoco field less developed than those about Lake Maracaibo.

Petroleum is produced in Venezuela under serious handicaps. Tropical heat and humidity, poorly drained lands, rank growth of vegetation, a scarcity of labour, and difficulty of transportation combine to render the task arduous. The entrance to Lake Maracaibo from the sea is so shallow that no vessels of over 11 ft. draught can enter. Consequently most of the oil must be sent out in light-draught barges or tankers to be reloaded onto ocean-going vessels. A few deep-water stations have been established on the Paraguaná peninsula, but the larger part of the oil is shipped first to the islands of Curazao or Aruba, where there are great refineries. As these islands belong to Holland there is less danger of political disorder than on Venezuelan territory.

Gold is found chiefly in the Yuruari region, about 100 m. S.W. of the principal mouth of the Orinoco and near the borders of British Guiana, where the famous El Callao mines are situated. These mines have produced as much as 181,040·2 Spanish oz. in one year (1886) and a total of 1,320,929·09 oz. from 1871 to 1890, while another report gives an output valued at $23,000,000 U.S. gold in the 15 years from 1884 to 1899. Some 10 or 12 mines are still being worked and yield about one million dollars per year. There are 14 copper mines, those at Aroa, 70 m. W. of Puerto Cabello and in railway communication with Tucacas (89 m.), being the most productive. The principal coal deposits developed are at Naricual, near Barcelona, and a railway has been constructed to bring the output to the port of Guanta. Deposits are being worked also, on a small scale, near Coro in the State of Falcón, and in several places about Lake Maracaibo. Asphalt is taken from several deposits—from Maracaibo, Cumaná, Pedernales in the Orinoco delta, and the famous Bermudez asphalt lake in the eastern part of the country. Sulphur is mined near Carúpano, and salt in Zulia and on the peninsula of Araya. The latter is a government monopoly, and the high prices at which it is sold constitute a serious prejudice to the people and to industries like that of meat packing.

GRAPH SHOWING PRODUCTION OF CRUDE PETROLEUM IN VENEZUELA

Pearl Fisheries.—One of the oldest of Venezuelan industries, the Margarita pearl fisheries, dates from the first exploration of this coast and was probably carried on before that by the natives. The fisheries are established about the islands of Margarita, Coche and Cubagua, the best producing beds being at El Tirano

and Macanao, the first north-east and the other north-west of Margarita.

Manufactures.—There are few manufacturing industries, and these are usually of the parasitic type, created by official favour and protected by high tariffs on imports in competition. The manufactures of this class include aerated waters, beer, candles, chocolate, cigarettes, cotton fabrics, hats, ice, matches, boots and shoes, drugs and medicines. There are a number of electric plants, several of which use water-power, one at El Encantado, 10 m. from Caracas, one at Mérida, and another at San Cristóbal, Táchira. There are plants using steam for motive power at Caracas, Maracaibo, Valencia and Puerto Cabello.

The total foreign trade of Venezuela in 1923 amounted to 309,396,512 bolivares (1 bolívar=$.19295). The imports aggregated 152,692,315 while the exports came to 156,704,197 bolivares. The countries furnishing the largest amounts of the imports were, in order: United States, Great Britain, Germany, France, the Netherlands, Spain and Italy, while the countries taking the largest amounts of exports were the Netherlands, United States, Spain, France, Great Britain and Germany. In 1923 the chief exports were valued as follows in bolivares: coffee, 68,945,726; petroleum, 27,321,920; cacao, 23,817,102; sugar, 5,359,128; balata, 4,084,588; hides, 3,515,550; cattle, 1,901,455; gold, 1,300,000; asphalt, 1,332,940; heron plumes, 1,017,735; and pearls, 740,880. Since 1923, petroleum has become the largest item of export.

Government.—The Government of Venezuela is that of a Federal republic of nominally independent, self-governing States. According to the provisions of the constitution adopted in 1925, the legislative power is vested in a national Congress of two houses—the Senate and Chamber of Deputies—which meets at Caracas every year. The Senate consists of two members from each State, or 40 members, who are elected by the State legislatures for a period of seven years. The Chamber consists of popular representatives, elected by direct vote, in the proportion of one deputy for each 35,000 of population, each State being entitled to at least one deputy, the Federal district and territories being entitled to representatives on the same terms.

The executive power is vested by the constitution in a president, two vice-presidents and a cabinet of ministers. The president and vice-presidents, who must be Venezuelans by birth and more than 30 years old, are elected by the national Congress. The presidential term is seven years, and the president cannot succeed himself. The president is assisted by a cabinet of seven ministers and the governor of the Federal district, their respective departments being interior, foreign relations, finance and public credit, war and navy, *fomento* (promotion), public works and public instruction.

The judicial power is vested in a supreme Federal court, called the Corte Federal y de Casación, and such subordinate tribunals as may be created by law. The Federal court consists of seven members, representing as many judicial districts of the republic, who are elected by Congress for periods of seven years, and are eligible for re-election. It is the supreme tribunal of the republic, and is also a court of appeal (*Casación*) in certain cases, as defined by law. The judicial organization of the States includes in each a supreme court of three members, a superior court, courts of first instance, district courts and municipal courts. The judicial terms in the States are for three years. In the territories there are civil and criminal courts of first instance, and municipal courts. The laws of Venezuela are well codified both as to law and procedure, in civil, criminal and commercial cases.

The State Governments are autonomous and consist of legislative assemblies composed of deputies elected by ballot for a period of three years, and for each a president and two vice-presidents chosen by the legislative assembly for a term of three years. The States are divided into districts and these into *municipios*, the executive head of which is a *jefe civil*. There is a municipal council of seven members in each district, elected by the municipios, and in each municipio a communal junta appointed by the municipal council. The governors of the Federal territories are appointees of the president of the republic, and the *jefe civil* of each territorial *municipio* is an appointee of the governor. The Federal District is the seat of Federal authority, and consists of a small territory surrounding Caracas and La Guaira, known in the territorial division of 1904 as the West district, and the island of Margarita and some neighbouring islands, known as the East district.

There are two classes of citizens in Venezuela—native-born and naturalized. The first includes the children of Venezuelan parents born in foreign countries; the latter comprises four classes: natives of Spanish-American republics, foreign-born persons, foreigners naturalized through special laws and foreign women married to Venezuelans. The power of granting citizenship to foreigners is vested in the president of the republic, who is also empowered to refuse admission to the country to undesirable foreigners, or to expel those who have violated the special law (April 11, 1903) relating to their conduct in Venezuelan territory. The right of suffrage is exercised by Venezuelan males over 21 years of age, and all electors are eligible to public office except where the constitution declares otherwise. Foreign companies are permitted to transact business in Venezuela, subject to the laws relating to non-residents and also to the laws of the country governing national companies.

Defence.—In 1925 the Venezuelan Navy consisted of three gunboats and a training ship with a personnel of a few hundred men. The standing army was composed of some 9,000 infantry, artillery and cavalry. In addition there was a reserve estimated to consist of about 100,000 men. In 1919 military service was made compulsory for all adult male citizens with certain exceptions. Service in the army or navy for two years in peace-time and during war at the president's pleasure was made compulsory with relegation to the reserve until the age of 45. A decree of April 17, 1920, provided for a military aviation school at Maracay.

Education.—In popular education Venezuela has done almost nothing worthy of record. The ruling classes and the Church have taken little interest in the education of the Indians and *mestizos*. According to the law of 1921 primary education is free and compulsory between seven and 14 years. Secondary education comprises two courses; one of general study occupying four years, and one of professional study occupying two years. Normal training is furnished by two institutions at Caracas. Among the special schools are schools of commerce and modern languages at the capital and other important cities, besides two schools of industrial arts and trades. Higher education is afforded by the Central University of Venezuela at Caracas. Physical education is compulsory in all schools up to the age of 21. Expenditure on education for 1924–25 was 4,648,345 bolivares. Further educational facilities are provided by a national library with 50,000 volumes, a national museum, with a valuable historical collection, the Cajigal Observatory, devoted to astronomical and meteorological work, and the Venezuelan Academy and National Academy of History—the first devoted to the national language and literature, and the second to its history.

Religion.—The Roman Catholic is the religion of the State, but freedom of worship is nominally guaranteed by law. The president, however, is empowered to deny admission into the country of foreigners engaged in special religious work not meeting his approval. Practically no other form of worship exists than that of the Roman Catholic Church. There is one archbishop (Caracas) and four suffragan bishops (Mérida, Guaiana, Barquisimeto and Guárico).

Finance.—The financial situation in Venezuela was for a long time extremely complicated and discreditable, owing to defaults in the payment of public debts, complications arising from the guarantee of interest on railways and other public works, responsibility for damages to private property during civil wars and bad administration. To meet increasing obligations, taxation has been heavily increased. The public revenues are derived from customs charges on imports and exports, transit taxes, cattle taxes, profits on coinage, receipts from State monopolies, receipts from various public services such as the post office, telegraph, Caracas waterworks, etc., and sundry taxes, fines and other sources.

The public debt of Venezuela dates back to the Revolutionary

War, when loans were raised in Europe for account of the united colonies of Colombia, Ecuador and Venezuela. The separation of the Colombian republic into its three original parts took place in 1830, and in 1834 the foreign debt contracted was divided among the three, Venezuela being charged with 28½%, or £2,794,826, of which £906,430 were arrears of interest. Other items were afterwards added to liquidate other obligations than those included in the above, chiefly on account of the internal debt. Several conversions and compositions followed, interest being paid irregularly. In 1880–81 there was a consolidation and conversion of the republic's foreign indebtedness through a new loan of £2,750,000 at 3%, and in 1896 a new loan of 50,000,000 bolivares (£1,980,198) for railway guarantees and other domestic obligations. In Aug. 1904 these loans and arrears of interest brought the foreign debt up to £5,618,725, which in 1905 was converted into a "diplomatic" debt of £5,229,700 (3%). During these years Venezuela had been pursuing the dangerous policy of granting interest guarantees on the construction of railways by foreign corporations, which not only brought the Government into conflict with them on account of defaulted payments, but also through disputed interpretations of contracts and alleged arbitrary acts on the part of Government officials. In the civil wars the Government was also held responsible for damages to these properties and for the maltreatment of foreigners residing in the country. Some of these claims brought Venezuela into conflict with the Governments of Great Britain, Germany and Italy in 1903. Venezuelan ports were blockaded and there was an enforced settlement of the claims (about £104,417), which were to be paid from 30% of the revenues of the La Guaira and Puerto Cabello custom-houses. This settlement was followed by an adjustment of all other claims, payment to be effected through the same channels. In 1908 (July 31) the total debt of Venezuela (according to official returns) consisted of the following items:—

	Bolivares
Consolidated internal debt	63,171,818
Diplomatic debt (Spanish, French and Dutch)	7,014,569
" " (French, 1903–04)	5,733,490
" " of 1905	132,049,925
Unconsolidated debt in circulation	4,561,742
Total	212,531,544
or, at 25¼ bolivares per £	£8,417,091

Since 1909 the financial condition of Venezuela has steadily improved. The new law concerning public credit which came into force on June 15, 1923, introduced reforms in the administration of Venezuela's finances. Among other provisions it stipulated that certificates of the internal national consolidated debt which were received by the Treasury should be burned. The following details of the public debt of Venezuela in bolivares as outstanding on Dec. 31, 1923, are taken from the report of the Minister of Finance for 1924:—

External debt:	
National three per cent diplomatic debt	9,169,490·26
Three per cent diplomatic debt of 1905	58,948,145·00
Total	68,117,635·26
Internal debt:	
National internal three per cent consolidated debt	42,647,277·93
Three per cent inscribed debt	2,098,652·50
Total	44,745,930·43

The total indebtedness of the Venezuelan Government on Dec. 31, 1923 thus amounted to 112,863,565·69. The budget for 1924–25 estimated expenditure at 63,354,500 bolivares. Over one-fourth of this amount was allotted to the Ministry of Finance and Public Credit, one-fifth was assigned to the Ministry of War and the Navy, while more than one-sixth was given to the Ministry of the interior. In the budget the receipts of that year were estimated at 66,167,000 bolivares, an increase of 3,322,000 over those for 1923–24. In his message to Congress on April 25, 1925 President Gómez stated that the total national debt had been reduced to 99,445,723 bolivares by Jan. 1, 1925, and that on Dec. 31, 1924 there was in the treasury a surplus of 64,692,080·46 bolivares. On Dec. 31, 1926 the debt had been reduced still further to 85,108,452 bolivares and was being cancelled at the rate of about 8,000,000 bolivares per year. The bolívar was relatively stable during the World War. On Dec. 31, 1923 there were in circulation in Venezuela 35,129,695 bolivares of bank-notes, while the gold reserve aggregated 55,149,749. Of the paper currency 25,293,340 bolívares was supplied by the *Banco de Venezuela*. A shortage of silver in the circulating media has been met under the provisions of a law of 1918 by the minting of new silver coins.

The currency of Venezuela is on a gold basis, the coinage of silver and nickel is restricted, and the State issues no paper notes. Foreign coins were formerly legal tender but this has been changed by the exclusion of foreign silver coins and the acceptance of foreign gold coins as a commodity at a fixed value. Under the currency law of March 31, 1879, the thousandth part of a kilogramme of gold was made the monetary unit and was called a *bolívar*, in honour of the Venezuelan liberator. The denominations provided for are:—

Gold: 100, 20, *bolivares*.
Silver: 5, 2, 2.50, 2, 1 *bolivares;* 50, 20 *céntimos*.
Nickel: 12½ and 5 *céntimos*.

The silver 5-*bolívar* piece is usually known as a "dollar," and is equivalent to 48¼ pence, or 96½ cents U.S. gold. The old "peso" is no longer used except in accounts, and is reckoned at 4 bolivares, being sometimes described as a "soft" dollar. Silver and nickel are legal tender for 50 and 20 bolivares respectively. Paper currency is issued by the banks of Venezuela, Caracas and Maracaibo under the provisions of a general banking law, and their notes are accepted at their face value.

The metric weights and measures have been officially adopted by Venezuela, but the old Spanish units are still popularly used throughout the country. (G. M. McB.)

History.—The coast of Venezuela was the first part of the American mainland sighted by Columbus, who, during his third voyage in 1498, entered the Gulf of Paria and sailed along the coast of the delta of the Orinoco. In the following year a much greater extent of coast was traced out by Alonzo de Ojeda, who was accompanied by the more celebrated Amerigo Vespucci. In 1550 the territory was erected into the captain-generalcy of Caracas, and it remained under Spanish rule till the early part of the 19th century.

In 1810 Venezuela rose against the Spanish and on July 14, 1811 the independence of the territory was proclaimed. A war ensued which lasted for upwards of ten years, the principal events of which are described under BOLIVAR (*q.v.*), a native of Caracas and the leading spirit of the revolt. It was not till March 30, 1845 that the independence of the republic was recognized by Spain in the Treaty of Madrid. Shortly after the battle of Carabobo (June 24, 1821), by which the power of Spain in this part of the world was broken, Venezuela was united with the Federal State of Colombia, which embraced Colombia and Ecuador; but the Venezuelans were averse to the Confederation, and an agitation in 1829 resulted in the issue of a decree (Dec. 8) by Gen. Paez dissolving the union, and declaring Venezuela a sovereign and independent State. The following years were marked by recurring attempts at revolution, but on the whole Venezuela, during the period 1830–46, was less disturbed than the neighbouring republic owing to the dominating influence of Gen. Paez, who during the whole of that time exercised practically dictatorial power. In 1849 a successful revolution broke out and Paez was driven out of the country. The author of his expulsion, Gen. José Tadeo Monagas, had in 1847 been nominated, like so many of his predecessors, to the presidency by Paez, but he was able to win the support of the army and assert his independence of his patron. For a period of ten years, amidst continual civil war, Monagas was supreme. In 1854 slavery was abolished by presidential decree. After some years of civil war and confusion, Gen. Juan Crisóstomo Falcón established himself at the head of affairs where he remained from 1863 to 1868. In 1864 he divided Venezuela into 20 States and formed them into a Federal Republic. The two parties whose struggles had caused so much strife and

bloodshed were the Unionists, who desired a centralized government, and the Federalists, who preferred a federation of semi-autonomous provinces. The latter now triumphed. A revolt headed by Monagas broke out in 1868 and Falcón left the country and resigned the Presidency. In the following year Antonio Guzmán Blanco succeeded in making himself dictator, after a long series of battles in which he was victorious over the Unionists.

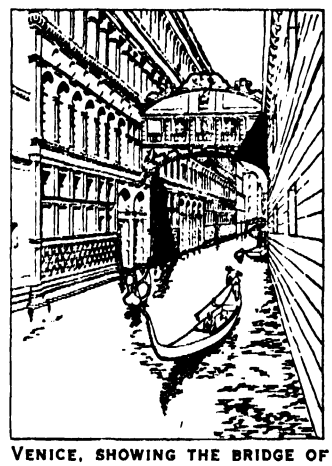
For two decades after the close of these revolutionary troubles in 1870 the supreme power in Venezuela was, for all practical purposes, in the hands of Guzmán Blanco. He evaded the clause in the constitution prohibiting the election of a president for successive terms of office by invariably arranging for the nomination of some adherent of his own as chief of the executive, and then pulling the strings behind this figurehead. The tenure of the presidential office was for two years, and at every alternate election Guzmán Blanco was declared to be duly and legally chosen to fill the post of chief magistrate of the republic. In 1889 there was an open revolt against the dictatorial system so long in vogue and Guzmán Blanco was overthrown. An election was held and Gen. Andueza Palacios was chosen president. A movement was set on foot for the reform of the constitution, the principal objects of this agitation being to prolong the presidential term to four years, to give Congress the right to choose the president of the republic, and to amend certain sections concerning the rights of persons taking part in armed insurrection arising out of political issues. All might have gone well for President Andueza had he not supposed that this extension of the presidential period might be made to apply to himself. His attempt to force this question produced violent opposition in 1891, and ended in a rising headed by Gen. Joaquín Crespo. This revolt, which was accompanied by severe fighting, ended in 1892 in the triumph of the insurgents, Andueza and his followers being forced to leave the country to save their lives. General Crespo became all-powerful; but he did not immediately accept the position of president. The reform of the constitution was agreed to, and in 1894 Gen. Crespo was duly declared elected to the presidency by Congress for a period of four years.

In April 1895 the long-standing dispute as to the boundary between British Guiana and Venezuela was brought to a crisis by the action of the Venezuelan authorities in arresting Inspectors Barnes and Baker, of the British Guiana police, with a few of their subordinates, on the Cuyuni river, the charge being that they were illegally exercising the functions of British officials in Venezuelan territory. Messrs. Barnes and Baker were subsequently released, and in due course made their report on the occurrence. The question began now to assume an acute stage, the Venezuelan minister in Washington having persuaded President Cleveland to take up the cause of Venezuela in vindication of the principles of the Monroe doctrine. On Dec. 18, 1895 a message was sent to the United States Congress by President Cleveland practically stating that any attempt on the part of the British Government to enforce its claims upon Venezuela as regards the boundary between that country and Guiana without resort to arbitration would be considered as a *casus belli* by his Government. The news of this message caused violent agitation in Caracas and other towns. A league was formed binding merchants not to deal in goods of British origin; patriotic associations were established for the purpose of defending Venezuela against British aggression, and the militia were embodied. The question was subsequently arranged in 1899 by arbitration, and by the payment of a moderate indemnity to the British officers and men who had been captured. Diplomatic relations between the two countries, which had been broken off in consequence of the dispute, were resumed in 1897.

In 1898 Gen. Crespo was succeeded as president by Señor Ignacio Andrade. Towards the end of the year a revolutionary movement took place with the object of ousting Andrade from power. The insurrection was crushed, but in one of the final skirmishes a chance bullet struck Gen. Crespo, who was in command of the Government troops, and he died from the effects of the wound. A subsequent revolt overthrew President Andrade in 1900. Gen. Cipriano Castro then became president. During 1901 and 1902 the internal condition of the country remained disturbed, and fighting went on between the Government troops and the revolutionists. President Castro was for eight years a dictator, ruling by corrupt and revolutionary methods, and in defiance of obligations to the foreign creditors of the country. The wrongs inflicted by him on companies and individuals of various nationalities, who had invested capital in industrial enterprises in Venezuela, led to a blockade of the Venezuelan ports in 1903 by English, German and Italian warships. Finding that diplomacy was of no avail to obtain the reparation from Castro that was demanded by their subjects, the three powers unwillingly had recourse to coercion. The president, however, sheltered himself behind the Monroe doctrine and appealed to the Government of the United States to intervene. The dispute was finally referred by mutual consent to The Hague Court of Arbitration. The Washington Government had indeed no cause to be well disposed to Castro, for he treated the interests of Americans in Venezuela with the same high-handed contempt for honesty and justice as those of Europeans. The demand of the United States for a revision of what is known as the Olcott Award in connection with the Orinoco Steamship Company was in 1905 met by a refusal to reopen the case. Meanwhile the country, which up to the blockade of 1903 had been seething with revolutions, now became much quieter. In 1906, the President refused to allow M. Taigny, the French minister, to land, on the ground that he had broken the quarantine regulations. In consequence, France broke off diplomatic relations. In the following year, by the decision of The Hague Tribunal, the Venezuelan Government had to pay the British, German and Italian claims, amounting to £691,160; but there was still £840,000 due to other nationalities, which remained to be settled. The year 1907 was marked by the repudiation of the debt to Belgium, and fresh difficulties with the United States. Finally, in 1908 a dispute arose with Holland on the ground of the harbouring of refugees in Curaçoa. The Dutch minister was expelled, and Holland replied by the despatch of gunboats, which destroyed the Venezuelan fleet and blockaded the ports. In Dec. Gen. Castro left upon a visit to Europe. In his absence a rising against the dictator took place at Caracas, and his adherents were seized and imprisoned. Juan Vicente Gómez, the vice-president, now placed himself at the head of affairs.

Under the constitution of 1909, on Aug. 27, 1910 Congress elected Gómez constitutional President for four years. In June and July, 1911 Venezuela observed the centenary of her declaration of independence. During the rule of Gómez diplomatic relations with foreign nations that had been ruptured were resumed, and Venezuela undertook to pay those obligations to foreign nations upon which payments had lapsed.

According to the constitution the term of office of President Gómez ended on April 19, 1914. Upon that day a Congress of Deputies from the Venezuelan States adopted a provisional constitutional statute for the Union, which declared that all laws not inconsistent therewith should remain in force. It further provided that this Congress should elect a commander-in-chief of the national army at the same time that it elected a provisional president of the republic. Congress was also to frame a new pact of union for Venezuela, which should be submitted to the assemblies of the States for approval. The period of provisional rule should last until the new constitution had been ratified by the States and until the constitutional functionaries had taken their posts. On the same day Congress elected Victorino Márquez Bustillos, who had been Minister of War and the Navy, provisional President, and by a decree of the same day Bustillos appointed his ministers of State. Congress elected General Gómez commander-in-chief of the national army.



On May 3, 1915 the Congress chosen under the constitution of 1914 unanimously elected Gen. Gómez President of the Republic for the term ending April 19, 1922, but the president-elect did not assume the presidency. The provisional president continued to exercise authority while Gen. Gómez remained commander-in-chief of the army with the title president-elect of the republic. In May, 1922 Gen. Gómez was unanimously re-elected to the office of President of Venezuela. On June 19, a new constitution was promulgated which made some slight but im-

portant changes in the constitution of 1914. Articles 137 and 138 of that fundamental law, which stipulated that the provisional president and the vice-presidents of the republic should hold their offices until the new magistrates were inaugurated and that the commander of the national army should exercise his functions until the inauguration of the constitutional president, were omitted from the constitution of 1922. This constitution further provided that in case the president should be permanently disabled, he should be succeeded by the ranking vice-president. On June 24 following, Gen. Gómez relieved Márquez Bustillos of the nominal authority which the latter had exercised since 1914, and assumed the powers of president for the term ending in 1929. Venezuela became a member of the League of Nations in 1920. On July 24, 1925 a new constitution was adopted, making some slight changes in that of 1922.

Boundary Disputes.—The boundary dispute between Colombia and Venezuela, which had been submitted to the arbitration of the Swiss Federal Council, was decided in March, 1922 in favour of the Colombian contention; namely, that she was entitled to take possession of such portions of the territory in dispute as had been adjudged to her in accordance with the decision of the king of Spain in 1891.

VENICE (*Venezia*), a city and seaport of Italy, occupying one of the most remarkable sites in the world. At the head of the Adriatic, between the mountains and the sea, lies that part of the Lombard plain known as the Veneto. The whole of this plain has been formed by the *débris* swept down from the Alps by the rivers Po, Ticino, Oglio, Adda, Mincio, Adige, Brenta, Piave, Livenza, Tagliamento and Isonzo. The substratum of the plain is a bed of boulders, covered during the lapse of ages by a deposit of rich alluvial soil. The rivers when they debouch from the mountains assume an eastern trend in their effort to reach the sea. The result is that the plain is being gradually extended in an easterly direction, and cities like Ravenna, Adria and Aquileia, which were once seaports, lie now many miles inland. The encroachment of land on sea has been calculated at the rate of about three miles in a thousand years. A strong current sets round the head of the Adriatic from east to west. This current catches the silt brought down by the rivers and projects it in long banks, or *lidi*, parallel with the shore. In process of time some of these banks, as in the case of Venice, raised themselves above the level of the water and became the true shore-line, while behind them lay large lagoons, formed partly by the fresh water brought down by the rivers, partly by the salt-water tide which found its way in by the channels of the river mouths. On a group of these mud banks about the middle of the lagoon of Venice stands the city of Venice. The soil is an oozy mud which can only be made capable of carrying buildings by the artificial means of pile-driving; there is no land fit for agriculture or the rearing of cattle; the sole food supply is fish from the lagoon, and there is no drinking-water save such as could be stored from the rainfall.

VENICE, SHOWING THE BRIDGE OF SIGHS, JOINING THE DUCAL PALACE TO THE STATE PRISON, BUILT BY CONTINO IN THE 16TH CENTURY

The whole site of Venice is dominated by the existence of one great main canal, the Grand Canal, which, winding through the town in the shape of the letter S, divides it into two equal parts. This great canal was probably at one time the bed of a river flowing into the lagoons near Mestre. The smaller canals all serve as arteries to the Grand Canal and their windings follow the lines of construction originally determined by the channels which traversed the islands of the lagoon. One other broad canal, once the bed of the Brenta, divides the island of the Giudecca from the rest of the city and takes its name from that island. The alleys or *calli* number 2,327, with a total length of 89¾ m.; the canals number 177 and measure 28 m. The ordinary Venetian house was built round a courtyard, and was one storey high; on the roof was an open *loggia* for drying clothes; in front, between the house and the water, ran the *fondamenta* or quay. The earliest churches were built with cemeteries for the dead; and thus we find the nucleus of the city of Venice, little isolated groups of dwellings each on its separate islet, scattered, as Cassiodorus, secretary to Theodoric the Great, says, in a letter dated A.D. 523, like sea-birds' nests over the face of the waters. Some of the islets were then still uninhabited, overrun with a dense low growth which served as cover for game and even for wolves.

Gondolas.—The characteristic conveyances on the canals of Venice are the gondolas, flat-bottomed boats, some 30 ft. long by 4 or 5 ft. wide, curving out of the water at the ends, with ornamental bow and stern pieces and an iron beak (*ferro*), resembling a halberd, which is the highest part of the boat. The gondolier stands on a *poppa* at the stern with his face towards the bow, and propels the gondola with a single oar. There is a low cabin (*felze*) for passengers; the ordinary gondolas can take four or six persons, and larger ones (*barca* or *battello*) take eight. Gondolas are mentioned as far back as 1094, and, prior to a sumptuary edict passed by the great council in 1562 making black their compulsory colour, they were very different in appearance from now. Instead of the present boat, with its heavy black cabin and absence of colouring, the older forms had an awning of rich stuffs or gold embroideries, supported on a light arched framework open at both ends; this is the gondola still seen in Carpaccio's and Gentile Bellini's pictures (*c.* 1500). There are also frequent steamer services along the Grand Canal to the Lido and the other islands of the lagoon.

Byzantine Architecture.—We can trace the continuous growth of Venice through the successive styles of Byzantine, Gothic, early Renaissance and late Renaissance architecture. (*See* Ruskin's *Stones of Venice.*) The two most striking buildings in Venice, St. Mark's and the Doge's Palace, at once give us an example of the two earlier styles, the Byzantine and the Gothic, at least in their general design, though both are so capricious in development and in decoration that they may more justly be considered as unique specimens rather than as typical examples of their respective styles. In truth, owing to its isolated position

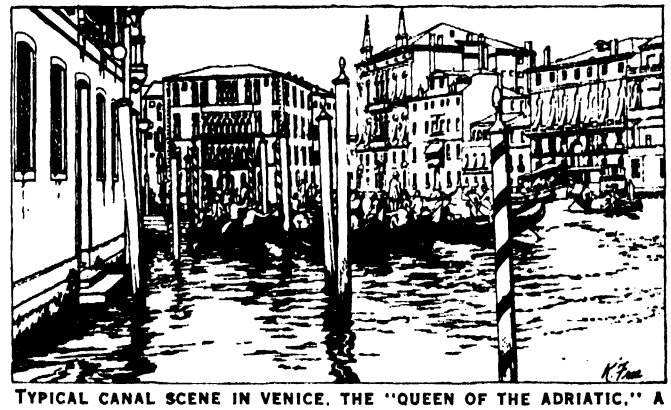
on the very verge of Italy, and to its close connection with the East, Venetian architecture was a distinctly independent development.

St. Mark's.—The church of St. Mark's, originally the private chapel of the doge, is unique in respect of its richness of material and decoration. It was adorned with the spoils of countless other buildings, both in the East and on the Italian mainland. A law of the republic required every merchant trading to the East to bring back some material for the adornment of the fane. Indeed, the building is a museum of sculpture of the most varied kind, nearly every century from the 4th down to the latest Renaissance being represented. The present church is the third on this site. Soon after the concentration at Rialto (see *History* below), a small wooden church was erected about the year 828 for the reception of the relics of St. Mark, brought from Alexandria. St. Mark then became the patron saint of Venice in place of St. Theodore. This church was burned in 976 along with the ducal palace in the insurrection against the Doge Candiano IV. Pietro Orseolo and his successors rebuilt it on a larger scale. About 1063 the Doge Contarini began to remodel St. Mark's, Byzantine architects having a large share in the work: but Lombards were also employed, giving birth to a new style, peculiar to the district.

In plan (*see* the article ARCHITECTURE) St. Mark's is a Greek cross of equal arms, covered by a dome in the centre, 42 ft. in diameter, and by a dome over each of the arms. The plan is derived from the Church of the Holy Apostles at Constantinople, now covered by the mosque of Mahommed II., and bears a strong resemblance to the plan of St. Front at Périgueux in France (1120). The addition of a narthex before the main front and a vestibule on the northern side brings the whole western arm of the cross to a square on plan. In elevation the façade seems to have connection with the five-bayed façade of the Kahriyeh Jamè, or mosaic mosque, at Constantinople. The exterior façade is enriched with marble columns brought from Alexandria and other cities of the East. Mosaics are employed to decorate the spandrils of the arches. Only one of the original mosaics now exists. It represents the translation of the body of St. Mark, and gives us a view of the west façade of the church as it was at the beginning of the 13th century before the addition of the ogee gables. The top of the narthex forms a wide gallery, communicating with the interior at the triforium level. In the centre of this gallery stand the four colossal bronze horses which belonged to some Graeco-Roman triumphal quadriga, and were brought to Venice by the Doge Enrico Dandolo in 1204. The south façade was reconstructed in 1865–78.

Mosaic is the essential decoration of the church, and the architectural details are subordinated to the colour scheme. The oldest remaining belong to the 12th century, and many of them, for example those of the domes of the atrium, are among the finest of their kind; but the greater part have been restored in the 16th–19th centuries. Below the mosaics the walls and arches are covered with rare marbles, porphyries and alabaster from ancient columns sawn into slices and so arranged in broad bands as to produce a rich gamut of colour.

The eastern crypt, or *confessio*, extends under the whole of the choir and has three apses, like the upper church. Below the nave is another crypt. The floors of both crypts have sunk considerably and are often under water; this settlement accounts for the inequalities of the pavement. The original part of the magnificent mosaic pavement probably dates from the same period as the pavement at Murano, exactly similar in style, material and workmanship, which bears the date 1140. The pavement consists partly of *opus Alexandrinum* of red and green porphyry mixed with marbles, partly of tessellated work of glass and marble.



The choir stands about 4 ft. above the nave and is separated from it by a marble rood-screen, on the architrave of which stand fourteen figures, the signed work of Jacobello and Pietro Paolo delle Masegne, 1394.

The Pala d'oro, or retable of the high altar (within which rests the body of St. Mark), is one of the chief glories of St. Mark's. It is one of the most magnificent specimens of goldsmiths' and jewellers' work in existence. It was ordered in 976 at Constantinople by the Doge Pietro I. Orseolo, and was enlarged and enriched with gems and modified in form, first by a Greek artificer in 1105, and then by Venetians between 1209 and 1345. It is composed of figures of Christ, angels, prophets and saints, in Byzantine enamel run into gold plates. The treasury of St. Mark's contains magnificent church plate and jewels.

Byzantine Palaces.—Fine examples of Venetian Byzantine palaces—at least of the façades—are still to be seen on the Grand Canal and in some of the small canals. The interiors have been modified past recognition of their original disposition. The Byzantine palace seems to have had twin angle-towers—such as those of the Ca' Molin on the Riva degli Schiavoni, where Petrarch lived. The Fondaco dei Turchi (13th century), now the Natural History Museum, also has two angle-towers. The façades presented continuous colonnades on each floor with semicircular high stilted arches, leaving a very small amount of wall space. The buildings were usually battlemented in fantastic form. A good specimen may be seen in Lazzaro Sebastiani's picture of the piazzetta, in the Museo Civico. There on the right we see the handsome building of the old bakery, occupying the site of the present library; it has two arcades of Saracenic arches and a fine row of battlements. Other specimens still in existence are Palazzo Loredan and Palazzo Farsetti (now the municipal buildings), and the splendid Palazzo Da Mosto, all on the Grand Canal. The richest ornamentation was applied to the arches and string courses while plaques of sculpture, roundels and coats of arms adorned the façades. The remains of a Byzantine façade now almost entirely built into a wall in the Rio di Ca' Foscari offer us excellent illustration of this elaborate style of decorative work.

Gothic Architecture.—Venetian Gothic, both ecclesiastical and domestic, shares most of the characteristics of north Italian Gothic generally. The material, brick and terra-cotta, is the determining cause of the characteristics of north Italian Gothic.

The Ducal Palace.—Soon after the concentration at Rialto the doge Angelo Particiaco began an official residence for the head of the state, a small, strongly fortified castle; one of its massive angle-towers is now incorporated in St. Mark's and serves as the treasury. It was burnt in 976 and again in 1106. Sebastian Ziani (1173–1179) restored and enlarged the palace. Of his work some traces still remain in the richly sculptured bands built in at intervals along the 14th-century façade on the Rio, and part of the handsome larch-wood beams which formed the loggia of the piazzetta façade, still visible on the inner wall of the present loggia. The palace was begun by Pietro Gradenigo in 1309.

TYPICAL CANAL SCENE IN VENICE, THE "QUEEN OF THE ADRIATIC," A CITY OF CANALS AND BRIDGES. THERE ARE 177 CANALS, SPANNED BY MORE THAN 400 BRIDGES, AND GONDOLAS TAKE THE PLACE OF CARRIAGES AND MOTORS

Towards the end of the 14th century, this façade, with its lower colonnade, upper loggia with handsome Gothic tracery, and the vast impending upper storey, which give to the whole building its striking appearance and audacious design, had been carried as far as the tenth column on the piazzetta side. In 1424 the building was resumed and carried as far as the north-west angle, near St. Mark's, thus completing the sea and piazzetta façades of two storeys with open colonnades, forming a long loggia on the ground

and first floors, with seventeen arches on the sea front and eighteen on the other façade. Above this is a lofty third storey, pierced with a few large windows, with pointed arches once filled with tracery, which is now lost. The whole surface of the ponderous upper storey is covered with a diaper pattern in slabs of creamy white Istrian stone and red Verona marble, giving a delicate rosy-orange hue to the building. Very beautiful sculpture, executed with an ivory-like minuteness of finish, is used to decorate the whole building with wonderful profusion. The great gateway, the Porta della Carta, was added in 1439–43 from designs by Giovanni Buon and his son Bartolomeo. The block of buildings in the interior, connecting the Porta della Carta with the Rio wing, was added about 1462. Later a fire consumed the earlier buildings along the Rio, which were replaced by the present structure.

The great internal court is surrounded with arcading. From the interior of the court access is given to the upper loggia by a very beautiful early Renaissance staircase, built in 1484–1501 by Antonio Rizzo. Two colossal statues of Neptune and Mars at the top of these stairs were executed by Jacopo Sansovino in 1554 —hence the name "giants' staircase." Owing to the fire of 1574, the fine series of early Paduan and Venetian frescoes in the chief rooms was lost. At present the magnificent council chambers for the different legislative bodies of the Venetian republic and the state apartments of the doges are highly decorated with gilt carving and panelling in the style of the later Renaissance. On the walls of the chief council chambers are a magnificent series of oil-paintings by Tintoretto and others—among them his masterpiece, "Bacchus and Ariadne," and his enormous picture of Paradise, the largest oil-painting in the world.

Gothic Churches and Palaces.—Among the many Gothic churches of Venice the largest are the Franciscan church of Santa Maria Gloriosa dei Frari (begun in 1338), and the Dominican church of SS. Giovanni e Paolo (1246–1430). The Frari is remarkable for its splendid works of art, including Titian's famous Assumption of the Virgin, and its fine choir-stalls and for the series of six eastern chapels which from outside give a very good example of Gothic brickwork, comparable with the even finer apse of the now desecrated church of San Gregorio. The church of SS. Giovanni e Paolo was the usual burying-place of the doges, and contains many noble mausoleums of various dates. Besides these two churches we may mention Santo Stefano, an interesting building of central Gothic, "the best ecclesiastical example of it in Venice." The west entrance is later than the rest of the edifice and is of the richest Renaissance Gothic, a little earlier than the Porta della Carta.

But it is in the domestic architecture of Venice that we find the most striking and characteristic examples of Gothic. The introduction of that style coincided with the consolidation of the Venetian constitution and the development of Venetian commerce both in the Levant and with England and Flanders.

The finest example of the ogival style is undoubtedly the Ca' d'Oro, so-called from the profusion of gold employed on its façade. It was built for Marino Contarini in 1422–40, a comparatively late date. With a fine collection of pictures and furniture, it was given to the State by Baron Franchetti in 1916.

Contarini was to some extent his own architect. He had the assistance of Marco d' Amadeo, a master-builder, and of Matteo Reverti, a Milanese sculptor, who were joined later on by Giovanni Buon and his son Bartolomeo. By the year 1431 the façade was nearly completed, and Contarini made a bargain with Martino and Giovanni Benzon for the marbles to cover what was yet unfinished. But Contarini was not content to leave the marbles as they were. He desired to have the façade of his house in colour. The contract for this work, signed with Master Zuan de Franza, conjures up a vision of the Ca' d' Oro ablaze with colour and gleaming with the gold ornamentation from which it took its name.

Other notable examples are the Palazzo Ariani at San Raffaelle, with its handsome window in a design of intersecting circles; the beautiful window with the symbols of the four Evangelists in the spandrils, in the façade of a house at San Stae; the row of three Giustinian palaces at S. Barnaba; the Palazzo Priuli at San Severo, with a remarkably graceful angle-window, where the columnar mullion carries down the angle of the wall; the flamboyant balconies of the Palazzo Contarini Fasan; the Palazzo Bernardo on a side canal near S. Polo, a late central Gothic building (1380–1400).

Early Renaissance.—Towards the close of the 15th century Venetian architecture began to feel the influence of the classical revival; but, lying far from Rome and retaining still her connection with the East, Venice did not fall under the sway of the classical ideals either so quickly or so completely as most Italian cities. Indeed, in this as in the earlier styles, Venice struck out a line for herself and developed a style of her own, known as Lombardesque, after the family of the Lombardi (Solari) who came from Carona on the Lake of Lugano. The essential point about the style is that it is intermediary between Venetian Gothic and full Renaissance. We find it retaining some traces of Byzantine influence in the decorated surfaces of applied marbles, and in the roundels of porphyry and verde antico, while it also retained certain characteristics of Gothic, as, for instance, in the pointed arches of the Renaissance façade in the courtyard of the ducal palace designed by Antonio Rizzo (1499).

Churches.—The most perfect example of this style in ecclesiastical architecture is the little church of S. Maria dei Miracoli begun by Pietro Lombardo in 1481. The church is without aisles, and has a semicircular roof, and the choir is raised twelve steps above the floor of the nave. The walls, both internally and externally, are encrusted with marbles. The façade has the characteristic circular pediment with a large west window surrounded by three smaller windows separated by two ornamental roundels in coloured marble and of geometric design. Below the pediment comes an arcade with flat pilasters, which runs all round the exterior of the church. Two of the bays contain round-headed windows; the other three are filled in with white marble adorned by crosses and roundels in coloured marble.

Similar results are obtained in the magnificent façade of the Scuola di San Marco, at SS. Giovanni e Paolo, which has six semicircular pediments of varying size crowning the six bays, in the upper order of which are four noble Romanesque windows. The lower order contains the handsome portal with a semicircular pediment, while four of the remaining bays are filled with quaint scenes in surprisingly skilful perspective. The façade of San Zaccaria (1458–1515), the stately design of Anton Marco Gambello and Mauro Coducci, offers some slight modifications in the use of the semicircular pediment, the line of the aisle roof being indicated by quarter-circle pediments abutting on the façade of the nave. San Salvatore, the work of Tullio Lombardo (1530), is severer and less highly ornamented than the preceding examples, but its plan is singularly impressive, giving the effect of great space in a comparatively small area. In this connection we must mention the Scuola of S. Giovanni Evangelista at the Frari, with its fore-court and screen adorned by pilasters delicately decorated with foliage in low relief, and its noble staircase whose double flights unite on a landing under a shallow cupola. This also was the work of Pietro Lombardo and his son Tullio.

Early Renaissance palaces occur frequently in Venice and form a pleasing contrast with those in the Gothic style. The Palazzo Dario with its dedication, *Urbis genio,* and the Vendramin-Calergi or *Non nobis* palace, whose façade is characterized by its round-headed windows of grouped twin lights between columns, are among the more important; though beautiful specimens, such as the Palazzo Trevisan on the Rio della Paglia, and the Palazzo Corner Reali at the Fava, are to be found all over the city.

Later Renaissance.—In this period architecture in Venice lacks any peculiarly individual imprint. It is still characterized by great splendour; indeed, the library of San Marco, begun by Jacopo Sansovino in 1536, is justly considered the most sumptuous example of Renaissance architecture in the world. It is rich, ornate, yet hardly florid, distinguished by splendid effects of light and shade, obtained by a far bolder use of projections than had hitherto been found in the somewhat flat design of Venetian façades.

The old Procuratie were built by Bartolomeo Buon about 1514, the new by Scamozzi in 1580, yet it is clear that each belongs

to an entirely different world of artistic ideas. The Procuratie Vecchie is perhaps the longest arcaded façade in the world and certainly shows the least amount of wall space; the whole design is simple, the moulding and ornamentation severe. The Procuratie Nuove, which after all is merely Scamozzi's continuation of Sansovino's library, displays all the richness of that ornate building. It contains the museum of ancient sculpture, founded by Cardinal Domenico Grimani in 1523.

Among the churches of this period those of San Giorgio Maggiore and of the Redentore are both by Palladio. In 1631 Baldassare Longhena began the fine church of Santa Maria della Salute. With a large and handsome dome, a secondary cupola over the altar, and a striking portal and flight of steps, it occupies one of the most conspicuous sites in Venice on the point of land that separates the mouth of the Guidecca from the Grand Canal. In plan it is an octagon with chapels projecting one on each side. The façades of San Moisè and of Santa Maria del Giglio are good specimens of the baroque style.

Among the palaces of the later Renaissance the more remarkable are Sansovino's Palazzo Corner della Ca' Grande, Longhena's massive and imposing Palazzo Pesaro, the Palazzo Rezzonico, from designs by Longhena with the third storey added by Massari, Sammicheli's Palazzo Corner Mocenigo at San Polo, and Massari's well-proportioned and dignified Palazzo Grassi at San Samuele, built in 1705–45.

Modern Buildings.—In recent times the general prosperity of the city has brought about a revival of domestic and civic architecture both in the Venetian Gothic and the Renaissance Lombardesque style.

Among the most remarkable buildings in Venice are the *scuole,* or gild halls, of the various confraternities. The six *scuole grandi,* San Teodoro, S. Maria della Carità, S. Giovanni Evangelista, San Marco, della Misericordia and San Rocco, built themselves magnificent gild halls. The Scuola di San Marco is now a part of the town hospital, and besides its façade, it is remarkable for the handsome carved ceiling in the main hall (1463). Other beautiful ceilings are to be found in the great hall and the hall of the Albergo in the Scuola della Carità, now the Accademia containing the famous picture gallery, with a number of works returned by Austria in 1919 by Marco Cozzi of Vicenza. But the most magnificent of these gild halls is the Scuola di San Rocco, designed by Bartolomeo Buon in 1517 and carried out by Scarpagnino and Sante Lombardo. The façade on the Campo is large and pure in conception. The great staircase and the lower and upper halls contain an unrivalled series of paintings by Tintoretto.

Campanili.—Among the more striking features of Venice we must reckon the *campanili* or bell-towers. (*See* CAMPANILE.) These were at one time more numerous, earthquakes and subsidence of foundations have brought many of them down, the latest to fall being the great tower of San Marco itself, which collapsed on July 14, 1902. Its reconstruction was at once undertaken, and completed in 1912, together with that of Sansovino's beautiful Loggetta, on its east side. In a few other cases, for example at San Giorgio Maggiore, the fallen campanili were restored; but for the most part they were not replaced. The Venetian campanile usually stands detached from the church. It is almost invariably square. The campanile is usually a plain brick shaft with shallow pilasters running up the faces. It has small angle-windows to light the interior inclined plane or staircase, and is not broken into storeys with grouped windows as in the case of the Lombard bell-towers. Above the shaft comes the arcaded bell-chamber, frequently built of Istrian stone; and above that again the attic, either round or square or octagonal, carrying either a cone or a pyramid or a cupola. Among the existing campanili the oldest are San Geremia, dating from the 11th century, San Samuele from the 12th, San Barnaba and San Zaccaria from the 13th.

Public Monuments.—Venetian sculpture is for the most part ancillary to architecture; for example, Antonio Rizzo's "Adam" and "Eve" (1464), which face the giants'-staircase in the ducal palace, are parts of the decorative scheme; Sansovino's splendid monument to Tomaso Rangone is an essential feature of the façade of San Giuliano. The most successful Venetian sculpture is to be found in the many noble sepulchral private monuments. The jealousy of the Venetian republic forbade the erection of monuments to her great men. The sole exception is the superb equestrian statue in honour of the General Bartolomeo Colleoni, standing on the Campo SS. Giovanni e Paolo. It is by the Florentine Verrocchio, and was cast by Alessandro Leopardi, who was responsible for the graceful pedestal. Leopardi was also the creator (1505) of the three handsome bronze sockets in front of St. Mark's which held the flagstaffs of the banners of Cyprus, Morea and Crete, when the republic ruled them.

By the side of the sea in the piazzetta, on to which the west façade of the ducal palace faces, stand two ancient columns of Egyptian granite, brought as trophies to Venice by Doge Domenico Michieli in 1126. In 1180 they were set up with their present fine capitals and bases. The grey column is surmounted by a fine bronze lion of Byzantine style, cast in Venice for Doge Ziani about 1178 and in 1329 a marble statue of St. Theodore, standing upon a crocodile, was placed on the other column.

PAINTING

Painting developed relatively late in Venice, as is shown by the dates of the activity of Giacomo Bellini (1424–1470) and his sons Gentile (1429–1507) and Giovanni (1459–1516) of the Vivarini family of Murano (1440–1505) and of Vittore Carpaccio (1482–*c.* 1527). The greatest artists of the Venetian school are Titian (1477?–1576) and Tintoretto (1518–94): but Palma Vecchio (*c.* 1480–1528), Bonifacio, Paris Bordone, and Paolo Veronese are also important. Of later masters we may name Tiepolo, Canaletto and Guardi (*qq.v.*).

Institutions.—The arsenal was founded about the year 1104 by the doge Ordelap Falier. In 1304, on the design of Andrea Pisano, new building sheds and the rope walk were erected. Pisano's building sheds, nine in a row, with peculiarly shaped roofs, were still standing intact—until recently, but have been modified. In 1325 the second addition, the *arsenale nuovo,* was made, and a third, the *arsenale nuovissimo,* in 1473; a fourth, the *Riparto delle Galeazze,* about 1539; and in 1564 the fifth enlargement, the *Canal delle Galeazze e Vasca,* took place. The entire circuit of the arsenal, about two miles in extent, is protected by a lofty wall with turrets. The main door of the arsenal is the first example in Venice of the purely classical style. It is a noble portal, erected in 1460, from designs by Fra Giocondo, with the lion of St. Mark in the attic. The statuary, with S. Giustina on the summit of the tympanum, was added in 1571 and 1578. The whole design was modified in 1688 so as to represent a triumphal arch in honour of Morosini Peloponnesiaco, who brought from Athens to Venice the four lions in Pentelic marble which now stand before the gate. (On the largest of these lions is cut a runic inscription recording an attack on the Piraeus in the 11th century by Norse warriors of the Varangian guard, under Harold Hardrada, afterwards—1047—king of Norway.) The arsenal suffered frequently and severely from fires, the worst being those of 1509 and 1569; yet such was the wealth of Venice that her fleet crushed the Turks at Lepanto in 1571.

The Lido, which lies about 2 m. S.E. of Venice and divides the lagoon from the sea, has become a fashionable bathing-place. The point of San Nicolò del Lido is strongly fortified to protect the new entrance to the port. Inside the fortress lies the old Protestant burying-ground.

Libraries.—The library of San Marco contains upwards of 400,000 printed volumes and about 13,000 manuscripts. We may date the true foundation of the library to the donation of Cardinal Bessarion. The principal treasures of the collection, including splendid Byzantine book-covers, the priceless codices of Homer, the Grimani Breviary, an early Dante, etc., are exhibited under cases in the Sala Bessarione in the Zecca or mint where the library has been installed. Another library was left to the public by the munificence of Count Quirini-Stampalia, who bequeathed his collections and his house at Santa Maria Formosa to be held in trust for students. The state archives are housed in the Franciscan monastery at the Frari.

Harbour.—Under the republic commercial shipping used to enter Venice by the port of San Nicolò del Lido and lie along the quay called the Riva degli Schiavoni, in the basin of San Marco, and up the broad Giudecca Canal. But the mouth of the Lido entrance gradually silted up and, when trade expanded, the Italian Government resolved to reopen it. Two moles were run out in a south-westerly direction; the westerly is about 2 m., the easterly about 3 m. in length. The natural scour thus created has given a depth of 26 ft. of water through the sand-bank. The mean rise and fall of the tide is about 2 ft., but under certain conditions of wind the variation amounts to 5 ft. and over. Docks were constructed near the railway station, but in 1917 plans were made for a new port for Venice on the mainland, at Marghera, south of the railway line to Padua; in 1922 the canal of approach was opened by King Victor Emmanuel, and named in his honour, and in 1924 the construction of the main works was begun. The port, when finished, will cover twice the area of Venice itself, and will consist of parallel moles 3,000 ft. long with docks of 600 to 800 ft. between. Two moles will be built at first, with isolated jetties on the canal for oil ships. With the existing docks in Venice this will give the port a capacity of 10,000,000 to 12,000,000 tons a year. It is hoped that the industrial area, which is being built behind the docks, will create a considerable volume of trade. Behind the industrial area again a garden suburb to house 30,000 is being brought into existence by the municipality. Special customs facilities have been granted for the encouragement of trade in the new port. In 1926 6,722 ships of a total tonnage of 5,785,424 entered and cleared the port, disembarking 1,676,750 tons of merchandise, and embarking 232,652, and dealing with 76,199 passengers.

The ancient glass-bead industry (*conterie*), has regained its position through the union of the different factories. Venetian beads are now sent in large quantities to the various colonies in Africa, and to India, Sumatra and Borneo. Similarly, the glass industry has revived. New amalgams and methods of colouring have been discovered, and fresh forms have been diligently studied. Special progress has been made in the production of mirrors, electric lamps, candelabra and mosaics. New industries are those of tapestry, brocades, imitation of ancient stuffs, cloth of silver and gold, and Venetian laces for the manufacture of which there is a government school, with 500 girl pupils. (*See* LACE.)

Population and Administration.—In 1548 the population of Venice numbered 158,069; in 1607–29, 142,804; in 1706, 140,256; in 1785, 139,095; in 1881, 132,826; in 1921 171,615. The city is extremely healthy, and the climate naturally mild.

Under the republic, and until modern times, the water supply of Venice was furnished by the storage of rain-water supplemented by water brought from the Brenta in boats. The famous Venetian *pozzi*, or wells for storing rain-water from the roofs and streets, consisted of a closed basin with a water-tight stratum of clay at the bottom, upon which a slab of stone was laid; a brick shaft of radiating bricks laid in a permeable jointing material of clay and sand was then built. On the ground-level perforated stones set at the four corners of the basin admitted the rain-water, which was discharged from the roofs by lead pipes; this water filtered through the sand and percolated into the shaft of the well, whence it was drawn in copper buckets. The present water supply comes from S. Ambrogio near Padova, 20 m. away.

Of the 19,000 houses in Venice only 6,000 have drains and sinks, all the others discharge sewage through pipes directly or indirectly into the canals. With the rise and fall of the tide the discharge pipes are flushed at the bottom. An important investigation undertaken by the Bacterioscopical Laboratory, with regard to the pollution of the Venetian canals by the city sewage, led to the discovery that the water of the lagoons possesses autopurifying power, not only in the large canals but even in the smallest ramifications of the waterways.

The church is ruled by the patriarch of Venice, who is usually raised to the purple. The patriarchate dates from 1451, when on the death of Domenico Michiel, patriarch of Grado, its seat of that honour was transferred to the cathedral church of Castello in Venice, and Michiel's successor, Lorenzo Giustinian, assumed the title of patriarch of Venice. On the fall of the republic St. Mark's became the cathedral church of the patriarch. There are thirty parishes in the city of Venice and fifteen in the lagoon islands and on the littoral. (X.)

HISTORY

It is usually affirmed that the State of Venice owes its origin to the barbarian invasions of north Italy; that it was founded by refugees from the mainland cities who sought refuge from the Huns in the impregnable shallows and mud banks of the lagoons. Venice, like Rome and other famous cities, was an asylum city. But it is nearly certain that long before Attila and his Huns swept down upon the Venetian plain in the middle of the fifth century, the little islands of the lagoon already had a population of poor but hardy fisherfolk living in quasi-independence, thanks to their poverty and their inaccessible site. This population was augmented from time to time by refugees from the mainland cities of Aquileia, Concordia, Opitergium, Altinum and Patavium. But these did not mingle readily with the indigenous population; as each wave of barbarian invasion fell back, these refugees returned to their mainland homes, and it required the pressure of many successive incursions to induce them finally to abandon the mainland for the lagoon, a decision which was not reached till the Lombard invasion of 568. On each occasion, no doubt, some of the refugees remained behind in the islands, and gradually built and peopled the 12 lagoon townships, which formed the germ of the State of Venice and were subsequently concentrated at Rialto or in the city we now know as Venice. These 12 townships were Grado, Bibione, Caorle, Jesolo, Heraclea, Torcello, Murano, Rialto, Malamocco, Poveglia, Chioggia and Sottomarina. The effect of the final Lombard invasion is shown by the resolve to quit the mainland and the rapid building of churches which is recorded by the *Cronaca altinate*. The people who finally abandoned the mainland and took their priests with them are the people who made the Venetian republic. But they were not as yet homogeneous.

Independence.—There is little doubt that the original lagoon population depended for its administration, as far as it had any, upon the larger cities of the mainland. There is a tradition that Venice was founded by "consuls from Padua"; and Padua claimed complete control of the course of the Brenta down to its mouth at Malamocco. The destruction of the mainland cities, and the flight of their leading inhabitants to the lagoons, encouraged the lagoon population to assert a growing independence, and led them to advance the doctrine that they were "born independent." Their development as a maritime people, engaged in small trading and intimately acquainted with their home waters, led Belisarius to seek their help in his task of recovering Italy from the Goths. He was successful; and the lagoons became, theoretically at least, a part of the Eastern empire. But the empire was vast and weak, and its capital lay far away; in practice, no doubt, the lagoon population enjoyed virtual independence.

It was from Byzantium that the Venetian people received the first recognition of their existence as a separate community. Their maritime importance compelled Narses, the imperial commander, to seek their aid in transporting his army from Grado; and when the Paduans appealed to the Eunuch to restore their rights over the Brenta, the Venetians replied by declaring that islands of the lagoon and the river mouths that fell into the estuary were the property of those who had rendered them habitable and serviceable. Narses declined to intervene, Padua was powerless to enforce its claims and Venice established a virtual independence of the mainland. Nor was it long before Venice made a similar assertion to the imperial representative, Longinus, who invited the Venetians to give him an escort to Constantinople (which they did) and also to acknowledge themselves subjects of the empire. By dint of promising large concessions and trading privileges, he induced the Venetians to make an act of submission —though not upon oath. The terms of this pact resulted in the first diploma conferred on Venice as a separate community (584). But it was inevitable that, when the barbarians, Lombard or Frank, were once established on the mainland of Italy, Venice should be brought first into trading and then into political relations with its near neighbours, who as masters of Italy also put forward a claim to sovereignty in the lagoons. It is between the

two claims of east and west that Venice struggled for and achieved recognized independence.

Internal Fusion and Consolidation.—In 466, 14 years after the fall of Aquileia, the population of the 12 lagoon townships met at Grado for the election of one tribune from each island for the better government of the separate communities, and above all to put an end to rivalries which had already begun to play a disintegrating part. But when the lagoon population was largely augmented in 568 as the result of Alboin's invasion, these jealousies were accentuated, and in 584 it was found expedient to appoint 12 other tribunes, known as the *Tribuni Maiores*, who formed a kind of central committee to deal with all matters affecting the general weal of the lagoon communities. But the *Tribuni Maiores* were equally powerless to allay the jealousies of the growing townships which formed the lagoon community. Rivalry in fishing and in trading, coupled with ancient antipathies inherited from the various mainland cities of origin, were no doubt the cause of these internecine feuds. A crisis was reached when Christopher, patriarch of Grado, convened the people of the lagoon at Heraclea, and urged them to suppress the 12 tribunes and to choose a single head of the State. To this they agreed, and in 697 Venice elected her first doge, Paulo Lucio Anafesto.

The growing importance of the lagoon townships, owing to their maritime skill, their expanding trade, created by their position between east and west, their monopoly of salt and salted fish, which gave them a strong position in the mainland markets, rendered it inevitable that a clash must come over the question of independence, when either east or west should claim that Venice belonged to them; and inside the lagoons of growing prosperity, coupled with the external threat to their liberties, concentrated the population into two well-defined parties—what may be called the aristocratic party, because it leaned towards imperial Byzantium and also displayed a tendency to make the dogeship hereditary, and the democratic party, connected with the original population of the lagoons, aspiring to free institutions, and consequently leaning more towards the Church and the Frankish kingdom which protected the Church. The aristocratic party was captained by the township of Heraclea, which had given the first doge, Anafesto, to the newly formed community. The democratic party was championed first by Jesolo and then by Malamocco.

The Franks.—The advent of the Franks determined the final solution. The Emperor Leo, the Isaurian, came to open rupture with Pope Gregory II. over the question of images. The pope appealed to Liutprand, the powerful king of the Lombards, to attack the imperial possessions in Ravenna. He did so, and expelled the exarch Paul, who took refuge in Venice and was restored to his post by the doge of the Heraclean or Byzantine party, Orso, who in return for this assistance received the imperial title of *hypatos*, and trading rights in Ravenna. The pope, however, soon had cause for alarm at the spread of the Lombard power which he had encouraged. Liutprand proceeded to occupy territory in the Ducato Romano. The pope, looking about for a saviour, cast his eyes on Charles Martel, whose victory at Tours had riveted the attention of the world. Charles's son, Pippin, was crowned king of Italy, entered the peninsula at the head of the Franks, defeated the Lombards, took Ravenna and presented it to the pope, while retaining a feudal superiority. Desiderius, the last Lombard king, endeavoured to recover Ravenna. Charlemagne, Pippin's son, descended upon Italy, broke up the Lombard kingdom (774), confirmed his father's donation to the pope, and in reprisals for Venetian assistance to the exarch, ordered the pope to expel the Venetians from the Pentapolis. Venice was now brought face to face with the Franks under their powerful sovereign, who soon showed that he intended to claim the lagoons as part of his new kingdom. In Venice the result of this menace was a decided reaction towards Byzantium. In opposition to the Frankish claim, Venice resolved to affirm her dependence on the Eastern empire. But the democratic party, the Frankish party in Venice, was powerful. Feeling ran high. A crisis was rapidly approaching. The Byzantine Doge Giovanni Galbaio attacked Grado, the see of the Francophil Patriarch Giovanni, captured it, and flung the bishop from the tower of his palace. But the murdered patriarch was succeeded by his no less Francophil nephew Fortunatus, a strong partisan, a restless and indomitable man, who along with Obelerio of Malamocco now assumed the lead of the democratic party. He and his followers plotted the murder of the doge, were discovered, and sought safety at the court of Charlemagne, where Fortunatus strongly urged the Franks to attack the lagoons.

Meantime the internal politics of Venice had been steadily preparing the way for the approaching fusion at Rialto. The period from the election of the first doge to the appearance of the Franks was characterized by fierce struggles between Heraclea and Jesolo. At length the whole population agreed to fix their capital at Malamocco, a compromise between the two incompatible parties, marking an important step towards final fusion at Rialto.

That central event of early Venetian history was reached when Pippin resolved to make good his title as king of Italy. He turned his attention to the lagoon of Venice, which had been steadily growing in commercial and maritime importance, and had, on the whole, shown a sympathy for Byzantium rather than for the Franks. Pippin determined to subdue the lagoons. He gathered a fleet at Ravenna, captured Chioggia, and pushed on up the Lido towards the capital of the lagoons at Malamocco. But the Venetians, in face of the danger, once more moved their capital, this time to Rialto, that group of islands we now call Venice, lying in mid-lagoon between the *lidi* and the mainland. This step was fatal to Pippin's designs. The intricate water-ways and the stubborn Venetian defence baffled all his attempts to reach Rialto; the summer heats came on; the Lido was unhealthy. Pippin was forced to retire. A treaty between Charlemagne and Nicephorus (810) recognized the Venetians as subjects of the Eastern empire, while preserving to them the trading rights on the mainland of Italy which they had acquired under Liutprand.

The concentration at Rialto marks the beginning of the history of Venice as a full-grown State. The external menace to their independence had welded together the place and the people; the same pressure had brought about the fusion of the conflicting parties in the lagoon townships into one homogeneous whole. There was for the future one Venice and one Venetian people dwelling at Rialto, the city of compromise between the dangers from the mainland, exemplified by Attila and Alboin, and the perils from the sea, illustrated by Pippin's attack. The position of Venice was now assured.

The first doge elected in Rialto was Angelo Particiaco, a Heraclean noble, and his reign was signalized by the building of the first church of San Marco, and by the removal of the saint's body from Alexandria, as though to affirm and to symbolize the creation of united Venice.

GROWTH OF THE REPUBLIC

The history of Venice during the next 200 years is marked externally by the growth of the city, thanks to her increasing trade. In the mainland Venice gradually acquired trading rights, partly by imperial diploma, partly by the establishment and the supply of markets on the mainland rivers, the Sile and the Brenta. Internally this period is characterized by the attempt of three powerful families, the Particiachi, the Candiani and the Orseoli, to create an hereditary dogeship, and the violent resistance offered by the people. We find seven of the Particiachi, five Candiani and three Orseoli reigning in almost unbroken succession, until, with the ostracism of the whole Orseolo family in 1032, the dynastic tendency was crushed for ever.

The growing wealth of Venice soon attracted the cupidity of her piratical neighbours on the coast of Dalmatia. The swift Liburnian vessels began to raid the Lido, compelling the Venetians to arm their own vessels and thus to form the nucleus of their famous fleet, the importance of which was recognized by the Golden Bull of the Emperor Basil, which conferred on Venetian merchants privileges far more extensive than any they had hitherto enjoyed, on condition that the Venetian fleet was to be at the disposition of the emperor. But the Dalmatian raids continued to harass Venetian trade, till, in 1000, the great doge Pietro Orseolo II. attacked and captured Curzola and stormed

the piratical stronghold of Lagosta, crushing the freebooters in their citadel. The doge assumed the title of duke of Dalmatia, and a great step was taken towards the supremacy of Venice in the Adriatic, which was essential to the free development of her commerce and also enabled her to reap the pecuniary advantages to be derived from the Crusades. She now commanded the route to the Holy Land and could supply the necessary transport, and from the Crusades her growing aristocracy reaped large profits. Orseolo's victory was commemorated and its significance affirmed by the magnificent symbolical ceremony of the "wedding of the sea" (*Sposalizio del Mar*), celebrated henceforward every Ascension day. The result of the first three crusades was that Venice acquired trading rights, a Venetian quarter, church, market, bakery, etc., in many of the Levant cities, *e.g.*, in Sidon (1102) and in Tyre (1123). The fall of Tyre marks a great advance in development of Venetian trade; the republic had now passed beyond the Adriatic, and had taken an important step towards complete command of the Levant.

Rise of the Aristocracy.—This expansion of the trade of Venice resulted in the rapid development of the wealthier classes, with a growing tendency to draw together for the purpose of securing to themselves the entire direction of Venetian politics in order to dominate Venetian commerce. To achieve their object, a double line of conduct was imposed upon them: they had to absorb the powers of the doge, and also to deprive the people of the voice they possessed in the management of State affairs by their presence in the *concione* or general assembly of the whole community, which was still the fountain of all authority. The first step towards curtailing the power of the doge was taken in 1032, when the family of the Orseoli was finally expelled from Venice and the doge Domenico Flabianico was called to the throne. A law was then passed forbidding for the future the election of a doge-consort, a device by which the Particiachi, the Candiani and the Orseoli had each of them nearly succeeded in carrying out their dynastic ambitions. Further, two ducal councillors were appointed to assist the doge, and he was compelled, not merely permitted, to seek the advice of the more prominent citizens at moments of crisis. By this reform two important offices in the Venetian constitution—the privy council (*consiglieri ducali*) and the senate (the *pregadi* or invited)—came into being. Both were gradually developed on the lines desired by the aristocracy, till we reach the year 1171.

The growth of Venetian trade and wealth in the Levant roused the jealousy of Genoa and hostility of the imperial court at Constantinople, where the Venetians are said to have numbered 200,000 and to have held a large quarter of the city in terror by their brawls. The Emperor Manuel I., urged on by the Genoese and other rivals of Venice, seized the pretext. The Venetians were arrested and their goods confiscated. Popular feeling at Venice ran so high that the State was rashly swept into war with the empire. The doge Vitale Michiel II. led the expedition in person. It proved a disastrous failure, and on the return of the shattered remnants (1171) a great constitutional reform seemed necessary. The Venetians resolved to create a deliberative assembly, which should act with greater caution than the *concione*, which had just landed the state in a ruinous campaign. Forty members were elected in each of the six divisions of the city, giving a body of 480 members, who served for one year and on retiring named two deputies for each *sestiere* to nominate the council for the succeeding year. This was the germ of the great council, the Maggior Consiglio, which was rendered strictly oligarchic in 1296. As the duties of this council were to appoint all officers of State, including the doge, it is clear that by its creation the aristocracy had considerably curtailed the powers of the people, who had hitherto elected the doge in general assembly; and at the creation of Michiel's successor, Sebastiano Ziani (1172), the new doge was presented to the people merely for confirmation.

The assembly protested, but was appeased by the empty formula, "This is your doge an it please you." Moreover, still further to limit the power of the doge, the number of ducal councillors was raised from two to six. In 1198, on the election of Enrico Dandolo, the aristocracy carried their policy one step farther, and by the *promissione ducale*, or coronation oath, which every doge was required to swear, they acquired a powerful weapon for the suppression of all that remained of ancient ducal authority. The *promissione ducale* was binding on the doge and his family, and could be, and frequently was, altered at each new election, a commission, *Inquisitori sopra il doge defunto*, being appointed to scrutinize the actions of the deceased doge and to add to the new oath whatever provisions they thought necessary to reduce the dogeship to the position of a mere figurehead.

The 4th Crusade.—In spite of the check to their trade received from the Emperor Manuel in 1171, Venetian commerce continued to flourish, the Venetian fleet to grow and the Venetians to amass wealth. When the fourth crusade was proclaimed at Soissons, it was to Venice that the leaders applied for transport, and she agreed to furnish transport for 4,500 horses, 9,000 knights, 20,000 foot, and provisions for one year: the price was 85,000 silver marks of Cologne and half of all conquests. But Zara and Dalmatia had revolted from Venice in 1166 and were as yet unsubdued. Venetian supremacy in the Adriatic had been temporarily shaken. The 85,000 marks, the price of transport, were not forthcoming, and the Venetians declined to sail till they were paid. The doge Dandolo now saw an opportunity to benefit Venice. He offered to postpone the receipt of the money if the crusaders would reduce Zara and Dalmatia for the republic. These terms were accepted. Zara was recovered, and while still at Zara the leaders of the crusade, supported by Dandolo, resolved for their own private purposes to attack Constantinople, instead of making for the Holy Land. Constantinople fell (1204), thanks chiefly to the ability of the Venetians under Dandolo. The city was sacked, and a Latin empire, with Baldwin of Flanders as emperor, was established at Constantinople. (*See* ROMAN EMPIRE, LATER.)

In the partition of the spoils Venice claimed and received, in her own phrase, "a half and a quarter of the Roman empire." To her fell the Cyclades, the Sporades, the islands and the eastern shores of the Adriatic, the shores of the Propontis and the Euxine, and the littoral of Thessaly, and she bought Crete from the marquis of Monferrat. The accession of territory was of the highest importance to Venetian commerce. She now commanded the Adriatic, the Ionian islands, the archipelago, the Sea of Marmora and the Black sea, the trade route between Constantinople and western Europe, and she had already established herself in the seaports of Syria, and thus held the trade route between Asia Minor and Europe. She was raised at once to the position of a European power. In order to hold these possessions, she borrowed from the Franks the feudal system, and granted fiefs in the Greek islands to her more powerful families, on condition that they held the trade route open for her. The expansion of commerce which resulted from the fourth crusade soon made itself evident in the city by a rapid development in its architecture and by a decided strengthening of the commercial aristocracy, which eventually led to the great constitutional reform—the closing of the Maggior Consiglio in 1296, whereby Venice became a rigid oligarchy. Externally this rapid success awoke the implacable hatred of Genoa, and led to the long and exhausting Genoese wars which ended at Chioggia in 1380.

The Venetian Constitution.—The closing of the great council was, no doubt, mainly due to the slowly formed resolution on the part of the great commercial families to secure a monopoly in the Levant trade which the fourth crusade had placed definitely in their hands. The theory of the Government, a theory expressed throughout the whole commercial career of the republic, the theory which made Venice a rigidly protective state, was that the Levant trade belonged solely to Venice and her citizens. No one but a Venetian citizen was permitted to share in the profits of that trade. But the population of Venice was growing rapidly, and citizenship was as yet undefined. To secure for themselves the command of trade the leading commercial families resolved to erect themselves into a close gild, which should have in its hands the sole direction of the business concern, the exploitation of the East. This policy took definite shape in 1297, when the Doge Pietro Gradenigo proposed and carried the following meas-

ure: the supreme court, the Quarantia, was called upon to ballot, one by one, the names of all who for the last four years had held a seat in the great council created in 1171. Those who received twelve favourable votes became members of the great council. A commission of three was appointed to submit further names for ballot. The three commissioners at once laid down a rule that only those who could prove that a paternal ancestor had sat in the great council should be eligible for election.

This measure divided the community into three great categories: (1) those who had never sat in the council themselves and whose ancestors had never sat; these were of course the vast majority of the population, and they were excluded for ever from the great council; (2) those whose paternal ancestors had sat in the council; these were eligible and were gradually admitted to a seat, their sons becoming eligible on majority: (3) those who were of the council at the passing of this act or had sat during the four preceding years; their sons likewise became eligible on attaining majority. As all offices were filled by the great council, exclusion meant political disfranchisement. A close caste was created which very seldom and very reluctantly admitted new members to its body. The Heralds' college, the *avvogadori di comun,* in order to ensure purity of blood, were ordered to open a register of all marriages and births among members of the newly created caste, and these registers formed the basis of the famous *Libro d'oro.*

The closing of the great council and the creation of the patrician caste brought about a revolution among those who suffered disfranchisement. In the year 1300 the people, led by Marin Bocconio, attempted to force their way into the great council and to reclaim their rights. The doors were opened, the ringleaders were admitted and immediately seized and hanged. Ten years later a more serious revolution, the only revolution that seriously shook the State, broke out and was also crushed. This conspiracy was championed by Bajamonte Tiepolo, and seems to have been an expression of patrician protest against the *serrata,* just as Bocconio's revolt had represented popular indignation. Tiepolo, followed by members of the Quirini family and many nobles with their followers, attempted to seize the Piazza on June 15, 1310. They were met by the Doge Pietro Gradenigo and crushed. Quirini was killed, and Tiepolo fled.

The chief importance of the Tiepoline conspiracy lies in the fact that it resulted in the establishment of the Council of Ten. Erected first as a temporary committee of public safety to hunt down the remnant of the conspirators and to keep a vigilant watch on Tiepolo's movements, it was finally made permanent in 1335. The secrecy of its deliberations and the rapidity with which it could act made it a useful adjunct to the constitution, and it gradually absorbed many important functions of the State.

With the creation of the Council of Ten the main lines of the Venetian constitution were completed. At the basis of the pyramid we get the great council, the elective body composed of all who enjoyed the suffrage, *i.e.,* of the patrician caste. Above the great council came the senate, the deliberative and legislative body *par excellence.* To the senate belonged all questions relating to foreign affairs, finance, commerce, peace and war. Parallel with the senate, but extraneous to the main lines of the constitution, came the Council of Ten. As a committee of public safety it dealt with all cases of conspiracy; for example, it tried the Doge Marino Falier and the General Carmagnola; on the same ground all cases affecting public morals came within its extensive criminal jurisdiction. In the region of foreign affairs it was in communication with envoys abroad, and its orders would override those of the senate. It also had its own departments of finance and war. Above the senate and the Ten came the *Collegio* or cabinet, the administrative branch of the constitution. All affairs of State passed through its hands. It was the initiatory body; and it lay with the *Collegio* to send matters for deliberation either before the senate or before the Ten. At the apex of the pyramid came the doge and his council.

The Genoese Wars.—To turn now to the external events which followed on the fourth crusade. These events are chiefly concerned with the long struggle with Genoa over the possession of the Levant and Black sea trade. By the establishment of the Latin empire Venice had gained a preponderance. But it was impossible that the rival Venetian and Genoese merchants, dwelling at close quarters in the Levant cities, should not come to blows. They fell out at Acre in 1253. The first Genoese war began and ended in 1258 by the complete defeat of Genoa. But in 1261 the Greeks, supported by the Genoese, took advantage of the absence of the Venetian fleet from Constantinople to seize the city and to restore the Greek empire in the person of Michael VIII. Palaeologus. The balance turned against Venice again. The Genoese were established in the spacious quarter of Galata and threatened to absorb the trade of the Levant. To recover her position Venice went to war again, and in 1264 destroyed the Genoese fleet off Trepani, in Sicilian waters. This victory was decisive at Constantinople, where the emperor abandoned the defeated Genoese and restored Venice to her former position. The appearance of the Ottoman Turk and the final collapse of the Latin empire in Syria brought about the next campaign between the rival martime powers. Tripoli (1289) and Acre (1291) fell to the Mohammedan, and the Venetian title to her trading privileges.

To the scandal of Christendom, Venice at once entered into treaty with the new masters of Syria and obtained a confirmation of her ancient trading rights. Genoa replied by attempting to close the Dardanelles. Venice made this action a *casus belli.* The Genoese won a victory in the gulf of Alexandretta (1294); but on the other hand the Venetians under Ruggiero Morosini forced the Dardanelles and sacked the Genoese quarter of Galata. The decisive engagement, however, of this campaign was fought at Curzola (1299) in the Adriatic, when Venice suffered a crushing defeat. A peace, honourable to both parties, was brought about by Matteo Visconti, lord of Milan, in that same year. But the quarrel between the republics, both fighting for trade supremacy—that is to say, for their lives—could not come to an end till one or other was thoroughly crushed. The fur trade of the Black sea furnished the pretext for the next war (1353–54), which ended in the crushing defeat of Venice at Sapienza, and the loss of her entire fleet. But though Venice herself seemed to lie open to the Genoese, they took no advantage of their victory; they were probably too exhausted. The lord of Milan again arranged a peace (1355).

We have now reached the last phase of the struggle for maritime supremacy. Under pressure from Venice the emperor John V. Palaeologus granted possession of the island of Tenedos to the republic. The island commanded the entrance to the Dardanelles. Genoa determined to oppose the concession, and war broke out. The Genoese Admiral Luciano Doria sailed into the Adriatic, attacked and defeated Vettor Pisani at Pola in Istria, and again Venice and the lagoons lay at the mercy of the enemy. Doria resolved to blockade and starve Venice to surrender. The situation was extremely critical for Venice, but she rose to the occasion. Vettor Pisani was placed in command, and by a stroke of naval genius he grasped the weakness of Doria's position. Sailing to Chioggia he blocked the channel leading from the lagoons to the sea, and Doria was caught in a trap. Finally, in June 1380 the flower of the Genoese fleet surrendered at discretion. Genoa never recovered from the blow, and Venice remained undisputed mistress of the Mediterranean and the Levant trade.

Expansion to the Mainland.—But as the city became the recognized mart for exchange of goods between east and west, the freedom of the western outlet assumed the aspect of a paramount question. It was useless for Venice to accumulate eastern merchandise if she could not freely pass it on to the west. If the various states on the immediate mainland could levy taxes on Venetian goods in transit, the Venetian merchant would inevitably suffer in profits. The geographical position of Venice and her commercial policy alike compelled her to attempt to secure the command of the rivers and roads of the mainland, at least up to the mountains, that is to say, of the north-western outlet, just as she had obtained command of the south-eastern inlet. She was compelled to turn her attention, though reluctantly, to the mainland of Italy. Another consideration drove her in the same direction. During the long wars with Genoa the Venetians realized that, as they owned no meat or corn-producing territory, a

crushing defeat at sea and a blockade on the mainland exposed them to the grave danger of being starved into surrender. Both these pressing necessities, for a free outlet for merchandise and for a food-supplying area, drove Venice on to the mainland, and compelled her to initiate a policy which eventually landed her in the disastrous wars of Cambrai. The period with which we are now dealing is the epoch of the despots, the *signori*, and in pursuit of expansion on the mainland Venice was brought into collision first with the Scaligeri of Verona, then with the Carraresi of Padua, and finally with the Visconti of Milan. Hitherto Venice had enjoyed the advantages of isolation; the lagoons were virtually impregnable; she had no land frontier to defend. But when she touched the mainland she at once became possessed of a frontier which could be attacked, and found herself compelled either to expand or to lose the territory she had acquired.

Venice had already established a tentative hold on the immediate mainland as early as 1339. She was forced into war by Mastino della Scala, lord of Padua, Vicenza, Treviso, Feltre and Belluno, as well as of Verona, who imposed a duty on the transport of Venetian goods. A league against the Scala domination was formed, and the result was the fall of the family. Venice took possession of Padua, but in the terms of the league she at once conferred the lordship on the Carraresi, retaining Treviso and Bassano for herself. But it is not till we come to the opening of the next century that Venice definitely acquired land possessions and found herself committed to all the difficulties and intricacies of Italian mainland politics. On the death of Gian Galeazzo Visconti in 1402, his large possessions broke up. His neighbours and his generals seized what was nearest to hand. Francesco II. Carrara, lord of Padua, attempted to seize Vicenza and Verona. But Venice had been made to suffer at the hands of Carrara, who had levied heavy dues on transit, and moreover during the Chioggian War had helped the Genoese and cut off the food supply from the mainland. She was therefore forced in self-defence to crush the family of Carrara and to make herself permanently mistress of the immediate mainland. Accordingly when Gian Galeazzo's widow applied to the republic for help against Carrara it was readily granted, and after some years of fighting, the possessions of the Carraresi, Padua, Treviso, Bassano, commanding the Val Sugana route, as well as Vicenza and Verona, passed definitely under Venetian rule. This expansion of mainland territory was followed in 1420 by the acquisition of Friuli after a successful war with the Emperor Sigismund, thus bringing the possessions of the republic up to the Carnic and Julian Alps, their natural frontier.

Isolation of Venice.—Venice was soon made to feel the consequences of having become a mainland power, the difficulties entailed by holding possessions which others coveted, and the weakness of a land frontier. To the west the new duke of Milan, Filippo Maria Visconti, was steadily piecing together the fragments of his father's shattered duchy. He was determined to recover Verona and Vicenza from Venice, and intended, as his father had done, to make himself master of all north Italy. The conflict between Venice and Milan led to three wars in 1426, 1427 and 1429. Venice was successful on the whole. She established her hold permanently on Verona and Vicenza, and acquired besides both Brescia and Bergamo; and later she occupied Crema. The war of Ferrara and the peace of Bagnolo (1484) gave her Rovigo and the Polesine. This, with the exception of a brief tenure of Cremona (1499–1512), formed her permanent territory down to the fall of the republic. Her frontiers now ran from the seacoast near Monfalcone, following the line of the Carnic and Julian and Raetian Alps to the Adda, down the course of that river till it joins the Po, and thence along the line of the Po back to the sea. But long and exhausting wars were entailed upon her for the maintenance of her hold. The rapid formation of this land empire, and the obvious intention to expand, called the attention not only of Italy but of Europe to this power which seemed destined to become supreme in north Italy, and eventually led to the league of Cambrai for the dismemberment of Venice.

In 1453 Constantinople fell to the Ottoman Turks, and although Venice entered at once into treaty with the new power and desired to trade with it, not to fight with it, yet it was impossible that her possessions in the Levant and the archipelago should not eventually bring her into collision with the expanding energy of Mohammedan. Europe persistently refused to assist the republic to preserve a trade in which she had established a rigid monopoly, and Venice was left to fight the Turk single-handed. The first Turkish war lasted from 1464 to 1479, and ended in the loss of Negropont and several places in the Morea, and the payment by Venice of an annual tribute for trading rights. She was consoled, however, by the acquisition of Cyprus, which came into her possession (1488) on the extinction of the dynasty of Lusignan with the death of James II. and his son James III., Caterina Cornaro, James II.'s widow, ceding the kingdom of Cyprus to Venice, since she could not hope to maintain it unaided against the Turks. The acquisition of Cyprus marks the extreme limit of Venetian expansion in the Levant; from this date onward there is little to record save the gradual loss of her maritime possessions.

DECLINE

Exhausting as the Turkish wars were to the Venetian treasury, her trade was still so flourishing that she might have survived the strain had not the discovery of the Cape route to the Indies cut the tap-root of her commercial prosperity by diverting the stream of traffic from the Mediterranean to the Atlantic. When Diaz rounded the Cape in 1486 a fatal blow was struck at Venetian commercial supremacy. The discovery of the Cape route saved the breaking of bulk between India and Europe, and saved the dues exacted by the masters of Syria and Egypt. Trade passed into the hands of the Portuguese, the Dutch and the English. Venice lost her monopoly of oriental traffic.

League of Cambrai.—To complete her misfortunes, the European Powers, the church and the small states of Italy, partly from jealous greed of her possessions, partly on the plea of her treason to Christendom in making terms with Islam, partly from fear of her expansion in north Italy, coalesced at Cambrai in 1508 for the partition of Venetian possessions. The war proved disastrous for Venice. The victory of Agnadello (1510) gave the allies the complete command of Venetian territory down to the shores of the lagoon. But the mutual jealousy of the allies saved her. The pope, having recovered the Romagna and secured the objects for which he had joined the league, was unwilling to see all north Italy in the hands of foreigners, and quitted the union. The Emperor Maximilian failed to make good his hold on Padua, and was jealous of the French. The league broke up, and the mainland cities of the Veneto returned of their own accord to their allegiance to St. Mark. But the republic never recovered from the blow, coming as it did on the top of the Turkish wars and the loss of her trade by the discovery of the Cape route. She ceased to be a great power, and was henceforth entirely concerned in the effort to preserve her remaining possessions and her very independence. The settlement of the peninsula by Charles V.'s coronation at Bologna in 1530 secured the preponderance to Spain, and the combination of Spain and the church dominated the politics of Italy. Dread of the Turks and dread of Spain were the two terrors which haunted Venice till the republic fell.

Turkish Wars.—But the decline was a slow process. Venice still possessed considerable wealth and extensive possessions. Between 1499 and 1716 she went to war four times with the Turks, emerging from each campaign with some further loss of maritime territory. The fourth Turkish war (1570–73) was signalized by the glorious victory of Lepanto (1571), due chiefly to the prowess of the Venetians under their doge Sebastian Venier. But her allies failed to support her. They reaped no fruits from the victory, and Cyprus was taken from her after the heroic defence of Famagusta by Bragadino, who was flayed alive, and his skin, stuffed with straw, borne in triumph to Constantinople. The fifth Turkish war (1645–68) entailed the loss of Crete; and though Morosini reconquered the Morea for a brief space in 1685, that province was finally lost to Venice in 1716.

So far as European politics are concerned, the latter years of the republic are made memorable by one important event: the resistance which Venice, under the guidance of Fra Paolo Sarpi, offered to the growing claims of the Curia Romana, advanced by Pope

Paul V. Venice was placed under interdict (1606), but she asserted the rights of temporal sovereigns with a courage which was successful and won for her the esteem and approval of most European sovereigns.

But the chief glory of her declining years was undoubtedly her splendid art. Giorgione, Titian, Sansovino, Tintoretto, Paolo Veronese and Palladio all lived and worked after the disastrous wars of the league of Cambrai. During these years Venice became the great pleasure-city of Europe.

United Italy.—The end of the republic came when the French Revolution burst over Europe. Napoleon was determined to destroy the oligarchical Government, and seized the pretext that Venice was hostile to him and a menace to his line of retreat while engaged in his Austrian campaign of 1797. The peace of Leoben left Venice without an ally. The Government resolved to offer no resistance to the conqueror, and the doge Lodovico Manin abdicated on May 12, 1797. On Oct. 17, Napoleon handed Venice over to Austria by the peace of Campo Formio, and between 1798 and 1814 she passed from France to Austria and Austria to France till the coalition of that latter year assigned her definitely to Austria. In 1848 a revolution broke out and a provisional republican Government under Daniele Manin (*q.v.*) maintained itself for a brief space. In 1866 the defeat of Austria by the Prussians led to the incorporation of Venice in United Italy. (H. F. Br.)

THE TWENTIETH CENTURY

The New Port of Marghera.—By the beginning of the 19th century Venice had felt the need of a bigger port for her increasing trade and the necessity of some outlet for her growing population. It was everything not to shackle her progress and, at the same time, not to disfigure one of the most beautiful cities in the world. Many makeshift works which proved inadequate were carried out before the World War, such as the building of the auxiliary port of Bottenighi on the mainland. At last, in 1917, a great scheme for a big port, with modern conveniences and an adjacent industrial area, was laid before the Orlando Government, approved, and the work begun at once. But the disaster of Caporetto brought it to a standstill. It was only in 1923, under the Government of Mussolini, that the work could be resumed, and, within the space of six years, carried forward to a remarkable extent owing, in great part, to the invaluable collaboration of the chancellor of the exchequer (1926–28), Conte Volpi di Misurata, a Venetian, who had been one of the original promoters of the scheme. This new port of Marghera is on the mainland and, when finished, it is estimated that it will cover an area three times as large as that of Genoa. Moreover, it is the first in Italy where railway trucks can be loaded and unloaded on the quays, which are in direct communication with Mestre station. It has a yearly potentiality in loading and unloading of at least 1,000 tons of merchandise to every 3 ft. of port frontage. The three industrial zones lying to the north, west and south of the commercial port have nearly all been secured by business firms, and some 40 factories are ready for use (1928), while as many again are being built. Each zone has exit to the sea by means of canals; for example, the northern zone communicates with the sea by the *Canale Industriale Nord*. In the vicinity lies the *Porticciolo dei Petrolii*, the first example in Italy of a port built exclusively for inflammable merchandise.

A garden-city is being built on the Mestre-Padua road, to be linked up with the industrial area and will accommodate some 50,000 inhabitants. In short, Venice is determined not to live only on the glory of her past; and she still looks upon the Adriatic as *mare nostrum*.

Population.—The necessity of a well-planned outlet on the mainland for Venice can be gauged by the following statistics. Directly after the war the population of Venice stood at 147,000; by Jan. 1928 it had risen to 207,400. The average density of population in Italy is 126 inhabitants to a square kilometre; whereas that of Venice is 204 to the same area. Venetian families are patriarchal: nearly 11% are composed of ten or more members; 32% of six to nine members. The birth-rate of Venice, calculated at 33 per 1,000, is double that of the rest of Italy. Her death-rate is 17·7 per 1,000, while the average rate in Italy is 19 per 1,000.

Industries.—The Venetians depend for their livelihood on boat traffic and home industries. Flat-bottomed boats, filled with vegetables and fruit, coming across the lagoons from the mainland, are among the many picturesque sights of Venice, and have been graphically described by D'Annunzio in *Fuoco*. The gondoliers still ply their trade, and can never be entirely replaced by the small motor-launches, but they feel the rough edge of competition in a mechanical age, even in the city of the lagoons.

The glass industries, both of household goods and artistic productions, employ a number of artisans, who can earn up to 40 lire a day for the more skilled work. The various Murano factories have joined in a syndicate, and their work has greatly improved since more care is taken in the use of good models. The manufacture of coloured glass beads and mosaic work is also characteristic of Venice. Even more important are the worked iron and copper industries, and much carved furniture is made. The Venetian filigree jewellery, and long, fine gold chains are also attractive and beautifully made. The lace industry is carried on in Venice to a certain extent, but more especially in the lagoon towns of Burano and Torcello. A great deal has been done since the World War to revive home industries and introduce once more the fine old patterns.

Festivals.—Venice is still famous for her festivals. The chief events in her history have always been celebrated either by civic or religious functions. The 11th centenary of the "pious theft" of St. Mark's body from Alexandria was celebrated in the spring of 1928 with a procession round the Piazzetta and the Piazza of S. Marco, in which 50 bishops of Venetia and mitred Canons of San Marco, as well as other dignitaries of the Church, took part, robed in gorgeous vestments and recalling the pictures of Bellini and Carpaccio. The most characteristic feasts are the following: on Holy Thursday the Venetians used to celebrate their victory over Urico, the patriarch of Aquileia. He was forced to pay tribute of a bull and 12 pigs which were meant to represent the primate and the canons of the Chapter. Art and literature have immortalized the celebration of Ascension Day when the doge used to be rowed out to the lagoon by the Lido in his gala gondola, *il Bucintoro*, to perform the symbolic rite of throwing a ring into the waters, and espousing the Adriatic with these words: *Ti sposiamo, o mare nostro, in segno di vero e perpettuo dominio*. The ceremony originated from Ascension Day of the year A.D. 1000, when Pietro Orseolo II. set sail from Venice to conquer Istria and Dalmatia.

Two eminently popular festivals of votive origin are still kept: the Feast of the Madonna della Salute and that of *Il Redentore* (The Redeemer), to whose patronage the Venetians believed they owed their deliverance from the plague in 1576 and in 1630, and in whose honour they built the Churches of the Salute and the Redentore. On the Feast of the Salute (Nov. 1) the Venetians take votive offerings to the church, and end the day with private banquets for which it is customary to procure Dalmatian mutton as the chief dish. The Feast of the Redentore is celebrated on the third Sunday of July with a characteristic vigil kept by the people singing as they row about in boats of every size and shape which are festooned with lights. At dawn they row out to the Lido in great numbers for the sunrise.

Museums, Galleries and Libraries.—Although Venice suffered from enemy aircraft during the World War, none of her works of art were damaged. The following is a list of her museums, galleries and public libraries:—

The Doge's Palace, adjoining the Basilica of San Marco, with frescoed walls and ceilings, as well as easel-pictures by Titian, Tintoretto, Paul Veronese, etc. The names of the various halls: Sala del Collegio, del Senato, del Consiglio dei Dieci, del Maggior-Consiglio, etc., recall the days of the proud Republic.

Il Museo Archeologico occupies that part of the doge's palace where the doge used to have his apartment.

Il Museo Civico Correr, in the royal apartments, Piazza S. Marco, has valuable collections of pictures, armour, coins, maps, costumes of state, etc.

Il Museo Storico Navale, in the arsenal, has models of ancient

ships and of the Bucentauro.

L'Accademia delle Belle Arti, on the Grand canal, contains a unique collection of masterpieces of the Venetian school.

La Galleria di Arte Moderna, inaugurated in 1902, has an important collection of international works of art which have been purchased in greater part from the Biennial International Exhibition of Modern Art. This was instituted in 1895 in honour of the silver wedding of King Humbert and Queen Margherita, and is held in the public gardens. Since the Fascist Government has made it a State institution, its importance has increased.

La Pinacoteca Comunale, in Palazzo Querini, once the residence of the patriarch of Venice, has a notable collection of pictures and prints.

The State Archives are kept in the Franciscan monastery adjoining the Frari. It contains the so-called Golden Book of the patricians and documents dating from the time of Charlemagne.

La Biblioteca Nazionale Marciana, in the old quarters of St. Mark's library, was started on Sept. 4, 1362, with the collection of books given by Petrarch to the Republic. It now contains 400,000 volumes, 13,000 rare manuscripts, 1,000 editions of the Aldine press, and over 3,000 in cuneiform character.

VENIZELOS, ELEUTHERIOS (1864–), Greek statesman, was born in Crete Aug. 23, 1864 of a family which had emigrated from Greece in 1770. Having been educated in the schools of Syra and Athens and having taken a degree in the University of Athens at the age of 23, he practised law in Crete, but soon became a politician, and in the insurrection of 1889 was compelled to flee from the island. After his return and the re-establishment of tranquillity, Venizelos was elected a member of the Cretan Assembly, and in 1897 came into prominence as one of the leaders of the Cretan uprising; it was he who received the British, French and Italian admirals when they came to negotiate a settlement between the insurgents and the Turks early in Feb. of that year.

In Dec. 1898 Prince George of Greece landed in Crete as the High Commissioner of the Great Powers, and a few months later Venizelos became head of the Island Executive. But he soon found himself at variance with the Prince's autocracy, and in 1904 a complete rupture occurred. Subsequently the Venizelists were defeated at the polls, but the Cretan leader organized a revolt, which greatly increased the unpopularity of the High Commissioner who was accused of misruling the people. In Sept. 1906 the Prince left the island, his place being taken by M. Alex Zaimis, who was appointed not by the Powers, but by the King of Greece. From that time until 1909 Venizelos was sometimes Chief of the Cretan Government and sometimes Leader of the Opposition. But whilst the Cretans often came into sharp conflict with the Protecting Powers, Venizelos' wisdom and moderation were responsible for the generally friendly relations which existed, and his far-sightedness, particularly after the departure of M. Zaimis in Oct. 1908, and during the crisis of 1909, facilitated the union of Crete with Greece, which ultimately took place as a result of the first Balkan War.

In 1909 the military league headed a bloodless revolution against political corruption and court favouritism in Greece and invited Venizelos to come to Athens. He persuaded King George and the League that the best way out of a dangerous situation would be the revision of the Constitution by a National Assembly. Elections were held in Aug. 1910, and Venizelos, who had remained technically a Greek citizen during his Cretan political life, took his seat at Athens for the first time. The Chamber having been opened in September, a month later Venizelos became Prime Minister.

He was in a position to enforce practically any situation, including a republic, which he wished; but decided to work loyally with the King and his successors. The Constitution was successfully revised in 1911, reforms in the public services were introduced, and the reorganization of the army and of the navy were respectively placed in the hands of French and British Missions. In the spring of 1912 Venizelos was returned to power as the leader of an overwhelming majority in an ordinary Chamber which then replaced the Revisionary Assembly. By that time, too, the Prime Minister was busily occupied with the formation of the Balkan League, and on May 29, 1912, the Greco-Bulgarian Treaty was signed.

Whilst the Balkan Wars and Venizelos' diplomacy led to an unexpected Hellenic expansion, the assassination of King George at Salonika on March 18, 1913, removed a man who had always been in favour of moderation, and placed upon the throne his son Constantine, who had not forgiven, and who never really forgave, Venizelos for his attitude towards Prince George in Crete. When the World War broke out, therefore, the position of Greece was greatly complicated by the facts that she was bound to Serbia by a Treaty signed in the summer of 1913; that from the first Venizelos was an ardent supporter of the Allied cause; and that the King was in sympathy with the Central Powers. Before the entry of Turkey into the War, Venizelos openly favoured Hellenic assistance for the Entente in case of that entry, and early in 1915 the Prime Minister advocated concessions to Bulgaria, Greek support for Serbia, and Greek co-operation at the Dardanelles in exchange for the promise of important future compensations in Western Asia Minor. But though he appears originally to have approved of the idea, the King vetoed Venizelos' decision to accept this offer, and he was forced to resign, though he possessed a strong majority in the Chamber. In the election which followed in June the Venizelist party secured the return of 190 deputies out of a total of 316, of which the Chamber was then composed.

In spite of this, and with the excuse of the King's illness, Venizelos was not recalled to power until after the meeting of the Chamber in Aug. and by that time the situation had become seriously modified. The mobilization of Bulgaria on Sept. 29, 1915 brought into operation in equity if not in law, the Greco-Serbian Treaty of 1913 and bound Greece to help Serbia. A few days later, Venizelos extorted from the King reluctant consent to a Greek mobilization and to a Greek request that the Allies should furnish an army of 150,000 men to take the place of the contingent Serbia should have supplied under the Treaty.

Immediately after the original Allied landing at Salonika on Oct. 1 Venizelos secured a vote of confidence during an historic and stormy meeting of the Chamber, when he declared that if in aiding Serbia Greece was brought into contact with Germany she would act as her honour demanded. In spite of a formal protest against the Allied passage through Hellenic territory, this speech led to the second dismissal of Venizelos and to the open and final rupture between that statesman and the King, who, it would seem, always intended to withdraw his consent to an Hellenic entry into the War. Zaimis, the new Prime Minister, maintained his position for a month as a result of the patriotism of Venizelos, his friend from Cretan times, but, with the accession of Skouloudis to power, on Nov. 6 the Chamber was dissolved and a new election ordered for Dec. 19. Venizelos' party abstained from the polls in protest, M. Gounaris securing an overwhelming majority for his policy of neutrality.

Venizelos spent that winter and spring (1915–16) in endeavouring to compel the King to change his point of view. But the surrender of Eastern Macedonia to the Bulgarians in the summer of 1916 and the delay in the success of the Allied Campaign at

Salonika had strengthened the position of Constantine, and on Sept. 25, 1916, Venizelos, together with his principal supporters, sailed for Crete, whence he sent out proclamations calling upon all true patriots to flock to the standard of the Entente. Proceeding thence to Salonika, early in Oct. he founded a Provisional Government, which was recognized about two months later by Great Britain and France, though not by Italy. A call for volunteers was answered generously by the inhabitants of those parts of Greece not in Constantinist hands, but the Royalist Government countered this and other developments by causing a solemn anathema to be pronounced against Venizelos by the Archbishop of Athens.

After the dethronement and enforced departure of King Constantine, Venizelos returned to Athens on June 26, 1917, and took over the Government of the whole country. The June 15 Chamber was convoked, general mobilization was ordered, and Greece formally opened up hostilities upon the Allied side. But the removal of the King, the successes of the Central Powers, particularly in the Balkans, and an increased Greek desire for neutrality, backed up by German propaganda, were responsible for a great diminution of the Prime Minister's popularity, and the officers and functionaries retired on account of their political views formed a dangerous element in an opposition which became ever more active.

Between the Armistice of Nov. 1918 and his fall two years later, Venizelos and his colleagues, who represented Greece at the Peace Conference, were almost continuously absent in Paris and London and, during this period, they seemed to be reaping for Greece harvests beyond her dreams. About the end of April 1919 the Greeks were permitted, or encouraged, to land at Smyrna; a year later the Conference of San Remo promised large areas to Greece, and the Treaty of Sèvres (Aug. 10, 1920) coupled with the earlier Treaty of Neuilly (Nov. 27, 1919) gave Greece extraordinary advantages. During this period, too, the Hellenic representative won such admiration and played so brilliant a part that he became a leading figure in the counsels of the Allies. Nevertheless, at a moment when his triumph appeared to be complete, an attempt was made upon his life at a Paris station (Aug. 1920), and three months later (Nov. 14) he received a crushing defeat at the hands of the Greek electorate.

Many factors were present in this: the unpopularity of the war in Asia Minor and the continued mobilization, the maintenance of martial law, the bad administration of Venizelos' subordinates and injustices practised by the Corps de la Sûreté. Further, there was Venizelos' own continued absence; recollection of the foreign support on which he had called so largely, and Constantine's own increasing popularity. After the unexpected death of the young king Alexander, immediately before the election, the dynastic question, open mention of which had previously been prohibited, was brought into the forefront of the political struggle and, in what then became the direct issue between Constantine and Venizelos, the King won an overwhelming victory.

From the arrival of the King in Athens on Dec. 20, 1920, until his final abdication and second departure on Sept. 30, 1922, Venizelos took no official part in Greek affairs, though he continued to use his international influence to endeavour to mitigate the results of the Asiatic disaster, the seeds of which he had sown by his own policy. After the revolution (Sept. 1922), however, Venizelos for a time represented Greece in Western Europe, *inter alia* at the Conference of Lausanne which culminated in the peace signed with Turkey on July 24, 1923. In the following December, when the publication of that document and various other events had aggravated the existing internal dissension and when the election (Dec. 16) had again given his party a majority, Venizelos was persuaded to return to Athens, where he arrived on Jan. 4, 1924. King George was already then on leave of absence, Venizelos was Prime Minister from Jan. 11 till Feb. 4, when he resigned on the advice of his physician. He left Athens on March 10, just before the country adopted his policy of a republic. He now spent several years of leisure, living mostly in France. In 1928, however, he began to prepare a return to politics. M. Kaptrandair resigned from the leadership of his section of the Liberals, and Venizelos took his place, declaring this to be the best guarantee against a dictatorship. He brought about the fall of the Government, formed a new government with himself as premier on July 4, and secured a large majority in the election held on Aug. 19. During the autumn he visited Rome, Paris, London and Belgrade on diplomatic missions. In Rome he negotiated with Mussolini a treaty of friendship and arbitration which was signed in October. A treaty of commerce with Yugoslavia was signed in November and followed by a treaty of friendship in March, 1929. He also carried on negotiations for treaties with Bulgaria and Turkey. These activities greatly improved the diplomatic position of Greece and Venizelos turned his attention again toward internal problems.

Venizelos was left a widower with two sons (Kyriakos b. 1893 and Sophocles b. 1895) in 1895. On Sept. 15, 1921, he married Miss Helena Schilizzi, heiress of a Greek Chiot family established in England.

VENLO, a frontier town in the province of Limburg, Holland, on the right bank of the Maas, and a junction station 43 m. N.N.E. of Maastricht by rail. Pop. (1927), 22,422. Venlo, with narrow streets irregularly built, is not of the ordinary Dutch type in architectural style. The picturesque town hall (1595) contains some interesting paintings by Hubert Goltzius (1526–1583). The church dates from 1304. The leading industries are distilling, brewing, tanning, spinning, needlemaking and tobacco manufacture. There is also a considerable trade by river with Rotterdam. Venlo is joined by a bridge over the Maas with the opposite village of Blerik.

VENN, HENRY (1725–1797), English evangelical divine, was born at Barnes, Surrey, and educated at Cambridge. He took orders in 1747, and was elected fellow of Queens' College, Cambridge, in 1749. After holding a curacy at Barton, Cambridgeshire, he became curate of St. Matthew, Friday Street, London, and of West Horsley, Surrey, in 1750, and then of Clapham in 1754. In the preceding year he was chosen lecturer of St. Swithin's, London Stone. He was vicar of Huddersfield from 1759 to 1771, when he exchanged to the living of Yelling, Huntingdonshire. Besides being a leader of the evangelical revival, he was well known as the author of *The Compleat Duty of Man* (London, 1763), a work in which he intended to supplement the teaching embodied in the anonymous *Whole Duty of Man*. His son, John Venn (1759–1813), was one of the founders of the Church Missionary Society, and his grandson, Henry Venn (1796–1873), was honorary secretary of that society from 1841 to 1873.

VENNOR, GEORGE HENRY (1840–1884), Canadian geologist and meteorologist, was born at Montreal on Dec. 30, 1840. He graduated at McGill University in 1860 and, after a number of private scientific expeditions, was in 1866 placed on the staff of the Canadian geological survey. His studies and revised classification of the great Laurentian system of rocks brought him a wide reputation and election to the Royal Geographical Society. He traced the Liévre, Rouge and Gatineau rivers to their sources and called attention to the phosphate deposits of Ottawa county. Over a period of many years he studied the characters and courses of storms deducing a number of general principles. From 1877 to his death he published *Vennor's Almanac*. He was the author of *Our Birds of Prey; or the Eagles, Hawks and Owls of Canada* (1876), and contributed frequently to the *Canadian Naturalist* and the *British American Magazine*.

VENOSA (anc. *Venusia, q.v.*), a town and bishop's see of the Basilicata in the province of Potenza, Italy, on the eastern side

of Mount Vulture, 52 m. by rail S.S.E. of Foggia, 1,345 ft. above sea-level. Pop. (1921) 8,993. The castle, built in 1470, contains four stables each for 50 horses. Many fragments of Roman workmanship are built into the 15th century cathedral. The abbey church of SS. Trinità is historically interesting; it was consecrated in 1059 by Pope Nicholas II. and passed into the hands of the Knights of St. John in 1297. In the central aisle is the tomb of Alberada, the first wife of Robert Guiscard and mother of Bohemund. An inscription on the wall commemorates the great Norman brothers William Iron Arm (d. 1046), Brogo (murdered at Venosa in 1051), Humfrey (d. 1057) and Robert Guiscard (d. at Corfu in 1085). The bones of these brothers rest together in a simple stone sarcophagus opposite the tomb of Alberada. The church also contains some 14th-century frescoes. Behind it is a larger church, which was begun for the Benedictines about 1150.

See O. de Lorenzo, *Venosa e la Regione del Vulture* (Bergamo, 1906).

VENTENAT, ETIENNE-PIERRE (1757–1808), French botanist, was born in Limoges in 1757. He entered the congregation of St. Geneviève and had charge of their library, but at the time of the Revolution abandoned his religious connections in order to follow his taste for botany. His writings caused him to be named professor in the Republican lyceum of Paris and made a member of the Institute. His principal works are *Principes de botanique* (1794); *Tableau du règne végétal* (1794); *Le botaniste voyageur aux environs de Paris* (1803); *Le jardin de la malmaison* (1803); *Choix de plantes* (1803–1808). These were noted above all for the beauty of the plates executed under the author's direction by Redouté, Sallier, Plée, etc. Among a number of memoirs dealing with the problems of his science the *Dissertation sur les parties des mousses qui ont été regardées comme fleurs mâles et comme fleurs femelles* and *Sur les meilleurs moyens de distinguer le calici de la corolle* are notable.

VENTIDIUS, BASSUS, Roman general, was born at Asculum. He took part in the Social War and was made prisoner by Pompey the Elder. As a contractor for military transport he aided Caesar in raising an army for the conquest of Gaul and was later given a command under Caesar. In 46 A.D. he became a senator and tribune. After Caesar's death he supported Antony and rendered important aid in the war against D. Brutus by taking three legions, which he raised himself, in a spectacular march over the Apennines to join in the battle. He became Antony's chief lieutenant and for a brief period was consul of Rome. He was afterwards sent to the East where he carried on the wars against the Parthians with brilliant success.

VENTILATION, the process and practice of keeping an enclosed place supplied with proper air for breathing; and so, by analogy, a term used for exposing any subject to the winds of public criticism; (Lat. *ventilare,* from *ventus,* wind). The air which we breathe consists chiefly of two gases, oxygen and nitrogen, with certain small proportions of other gases, such as carbon dioxide, ozone and argon. Oxygen, which is the active and important constituent, and on which life and combustion depend, forms about one-fifth of the whole, while nitrogen, which is inert and acts as a diluent, forms nearly four-fifths. Of this mixture each adult person breathes some 2,600 gallons of 425 cu.ft. in 24 hours. In air that has passed through the lungs the proportion of oxygen is reduced and that of carbon dioxide increased. Of the various impurities that are found in the air of inhabited rooms, carbon dioxide forms the best practical index of the efficiency of the ventilation. The open air of London and other large inland towns contains about four parts by volume of the gas in 10,000 of air. In the country, and in towns near the sea, two to three and a half parts in 10,000 is a more usual proportion. Authorities on ventilation usually take four parts in 10,000 as the standard for pure air, and use the excess over that quantity in estimating the adequacy of the air supply. They differ however as to the excess quantity of carbon dioxide permissible under a good system of ventilation. It is generally admitted that the air in which people dwell and sleep should not in any circumstances be allowed to contain more than ten parts in 10.000. This has been accepted as the permissible proportion by Carnelley, Haldane and Anderson, after an extensive examination of the air of middle and lower-class dwellings.

Human Consumption of Air.—The rate at which an adult expires carbon dioxide varies widely with his condition of repose, being least in sleep, greater in waking rest, and very much greater in violent exercise. As a basis on which to calculate the air necessary for proper ventilation, we may take the production of carbon dioxide by an adult as 0·6 cu.ft. per hour. Hence he will produce per hour, in 6,000 cu.ft. of air, a pollution amounting to one part of carbon dioxide in 10,000 of air. If the excess of carbon dioxide were to be kept down to this figure (1 in 10,000), it would be necessary to supply 6,000 cu.ft. of fresh air per hour; if the permissible excess be two parts in 10,000 half this supply of fresh air will suffice; and so on. We therefore have the following relation between (1) the quantity of air supplied per person per hour, (2) the excess of carbon dioxide which results, and (3) the total quantity of carbon dioxide present, on the assumption that the fresh air that is admitted contains four parts (by volume) in 10,000:—

Air supplied per adult per hour	Carbon dioxide (Parts by volume in 10,000)	
Cubic feet	Excess due to respiration	Total quantity
1,000	6	10
1,200	5	9
1,500	4	8
2,000	3	7
3,000	2	6

Some investigators have maintained that, in addition to an increased proportion of carbon dioxide, air which has passed through the lungs contains a special poison. This view, however, is not accepted by others; J. S. Haldane and Lorrain Smith, for instance, conclude "that the immediate dangers from breathing air highly vitiated by respiration arise entirely from the excess of carbonic acid and deficiency of oxygen" (*Journ. Path. and Bact.* 1892). Carbon dioxide, however, is not the only agent that has to be reckoned with in badly ventilated rooms, for the unpleasant effects they produce may also be due to increase of moisture and temperature and to the odours that arise from lack of cleanliness. Again, though there may be no unduly large proportion of carbon dioxide present, the air of an apartment may be exceedingly impure when the criterion is the number of micro-organisms it contains. This also may be greatly reduced by efficient ventilation. Comparisons carried out by Carnelley, Haldane and Anderson (*Phil. Trans.* 1887, B) between schools known to be well ventilated (by mechanical means) and schools ventilated at haphazard or not ventilated at all showed that the average number of micro-organisms was 17 per litre in the former, and in the others 152. Results of great interest were obtained by the experiment of stopping the mechanical ventilators for a few hours or days. Tested by the proportion of carbon dioxide, the air of course became very bad; tested by the number of micro-organisms, it remained comparatively pure, the number being, in fact, scarcely greater than when ventilation was going on, and far less than the average in naturally ventilated schools. This proves the advantage of systematic ventilation.

Ventilation of Buildings.—Here four main points have to be considered: (1) the area of floor to be provided for each person; (2) the cubic capacity of the room required for each occupant; (3) the allowance to be made for the vitiation of the air by gas or oil burners; and (4) the quantity of fresh air which must be brought in and of vitiated air that must be extracted for each individual. The first will depend upon the objects to which the room is devoted, whether a ward of a hospital or a school or a place of public assembly. The purity of the air of a room depends to a great extent on the proportion of its cubic capacity to the number of inmates. The influence of capacity is, however, often overrated. Even when the allowance of space is very liberal, if no fresh air be supplied, the atmosphere of a room quickly falls below the standard of purity specified above; on the other hand, the space per inmate may be almost indefinitely reduced if sufficient means are provided for systematic ventilation. Large rooms are good, chiefly because of their action as reservoirs of air in those cases

(too common in practice) where no sufficient provision is made for continuous ventilation, and where the air is changed mainly by intermittent ventilation, such as occurs when doors or windows are opened. With regard to the third point, in buildings lighted by gas or oil the calculations for the supply of fresh and the extraction of foul air must include an allowance for the vitiation of air by the products of combustion. The rate at which this takes place may be roughly estimated in the case of gas by treating each cubic foot of gas burned per hour as equal to one person. Thus an ordinary burner giving a light of about 20 candles and burning 4 cu.ft. of gas per hour vitiates the air as much as four persons, and an incandescent burner as much as one and a half persons. A small reading-lamp burning oil uses the air of four men; a large central table lamp uses as much air as seven men. As to the fourth point there is great diversity of opinion. To preserve the lowest standard of purity tolerated by sanitarians, ventilation must go on at the rate per person of 1,000 cu.ft. per hour, and 3,000 cu.ft. per hour are required to preserve the higher standard on which some authorities insist. E. A. Parkes advised a supply of 2,000 cu.ft. of air per hour for persons in health and 3,000 or 4,000 cu.ft. for sick persons. In the case of a public assembly hall no great harm will occur to an audience occupying the room for a comparatively short time if 30 cu.ft. of air per minute are provided for each person. The United States book on school architecture gives a practical application to its remarks on this subject as follows:—

The amount of fresh air which is allowed to hospital patients is about 2,500 cu.ft. each per hour. Criminals in French prisons have to content themselves with 1,500 cu.ft. per hour. Assuming that we care two-thirds as much for the health of our children as we do for that of our thieves and murderers, we will make them an allowance of 1,000 cu.ft. each per hour, or about 16 cu.ft. per minute. Forty-eight children will then need an hourly supply of 48,000 cu.ft. Definite provision must therefore be made for withdrawing this quantity of foul air. No matter how many inlets there may be, the fresh air will only enter as fast as the foul escapes, and this can only find an outlet through ducts intended for that purpose, porous walls and crevices serving in cool weather only for inward flow. What, then, must be the size of the shaft to exhaust 48,000 cu.ft. per hour? In a shaft 20 ft. high, vertical and smooth inside, with a difference in temperature of 20°, the velocity will be about 2½ ft. per sec., or 9,000 ft. per hour; that is, it will carry off 9,000 cu.ft. of air per hour for every sq.ft. of its sectional area. To convey 48,000 cu.ft., it must have a sectional area of 5½ sq.ft.

A general idea of the floor area, cubic space and fresh air supply per inmate allowed by law or by custom in certain cases is given in the table below:—

Class of building	Floor area in feet per person	Cubic capacity in feet per person*	Cubic feet of fresh air supplied and foul air extracted per person
Schools	9 to 10	200	1,800
Barracks	70	720	1,800
Prisons	90	800	1,800
Concert halls and theatres	9	108	2,000
Billiards and smokerooms	..	..	2,000
Hospitals	120	1,440	2,000 to 3,000
Public libraries	20	2,400	2,500
Turkish baths	70	800	5,000
Workshops	120	1,440	5,000
Cowsheds, per cow	90	1,100	10,000
Stables, per horse	120	1,600	12,000

*In calculating the cubic capacity per person the height should not be measured beyond 12 ft. above the floor.

The supply of fresh air indicated in the table should not be regarded as entirely satisfactory, for the standard of purity suggested is low, and ought to be exceeded, but it might deter many from moving in the matter if a proper and higher standard were to be laid down at first. One of the most important points is the proper warming of the fresh air introduced into buildings, for unless that be done, when a cold day occurs all the ventilating arrangements will probably be closed. The fact should not be lost sight of that the air in a room may on the one hand be quite cold and yet very foul, and on the other, warm and yet perfectly fresh. To avoid draught the air should enter through a large number of small orifices, so that the currents may be thoroughly diffused. This is done by gratings. The friction of their bars, however, seriously diminishes their capacity for passing air, and careful experiments show conclusively that very ample grating area is required to deliver large volumes. The same remark applies to extracting-flues. Owing to the small size and the roughness of the surface the velocity of the upward current is small, and the quantity of air that passes out is often much less than is requisite.

Means of Ventilation.—That the atmosphere of a room should be changed by means of air currents, thereby securing proper ventilation, three things are necessary; (1) an inlet or inlets for the fresh air, (2) an outlet or outlets for the vitiated air, and (3) a motive force to produce and maintain the current. In systems which are distinguished by the general name of *mechanical* or *artificial* ventilation special provision is made for driving the air by fans, or by furnaces, or by other contrivances described elsewhere under HEATING AND VENTILATING. In what is called *natural* ventilation no special appliance is used to give motive force, but the forces are made use of which are supplied by (1) the wind, (2) the elevated temperature of the room's atmosphere, and (3) the draught of fires used for heating.

The chief agent in domestic ventilation in Great Britain is the chimney, the majority of houses being fitted with open grates; and when a bright fire is burning in an open grate, it rarely happens that any other outlet for foul air from a room need be provided. The column of hot air and burnt gases in the chimney is less heavy, because of its high temperature, than an equal column of air outside; the pressure at the base is therefore less than the pressure at the same level outside. This supplies a motive force compelling air to enter at the bottom through the grate and through the opening over the grate, and causing a current to ascend. The motive force which the chimney supplies has not only to do work on the column of air within the chimney in setting it in motion and in overcoming frictional resistance to its flow; it has also to set the air entering the room in motion and to overcome frictional resistance at the inlets. From want of proper inlets air has to be dragged in at a high velocity and against much resistance, under the doors, between the window sashes and through many other chinks and crevices. Under these conditions the air enters in small streams or narrow sheets, ill-distributed and moving so fast as to form disagreeable draughts, the pressure in the room is kept so low that an opened door or window lets in a deluge of cold air, and the current up the chimney is much reduced. If the attempt is made to stop draughts by applying sandbags and listing to the crevices at which air streams in matters only become worse in other respects; the true remedy of course lies in providing proper inlets. The discharge of air by an ordinary open fire and chimney varies widely, depending on the rate of combustion, the height and section and form of the chimney, and the freedom with which air is entering the room. About 10,000 cu.ft. per hour is probably a fair average, about enough to keep the air fresh for half a dozen persons. Even when no fire is burning the chimney plays an important part in ventilation; the air within an inhabited room being generally warmer than the air outside, it is only necessary that an up-current should be started in order that the chimney should maintain it, and it will usually be found that a current is passing up. When a room is occupied for any considerable length of time by more than about half a dozen persons, the chimney outlet should be supplemented by others, which usually take the form of gratings in the ceiling or cornices in communication with flues leading to the open air. These openings should be protected from down-draught by light flap valves of oiled silk or sheet mica.

With regard to inlets, a first care must be to avoid such currents of cold air as will give the disagreeable and dangerous sensation of draught. At ordinary temperatures a current of outer air to which the body is exposed will be felt as a draught if it

velocity exceeds 3 ft. or even 2 ft. per second. The current entering a room may, however, be allowed to move with a speed much greater than this without causing discomfort, provided its direction keeps it from striking directly on the persons of the inmates. To secure this, it should enter, not horizontally nor through gratings on the floor, but vertically through openings high enough to carry the entering stream into the upper atmosphere of the room, where it will mix as completely as possible with warm air before its presence can be felt. A favourite form of inlet is the Sheringham (fig. 1). When opened it forms a wedge-shaped projection into the room and admits air in an upward stream through the open top. It should be placed at a height of 5 ft. or 6 ft. above the level of the floor. Other inlets are made by using hollow perforated blocks of earthenware, called airbricks, built into the wall; these are often shaped on the inner side like an inverted louvre-board or venetian blind, with slots that slope so as to give an upward inclination to the entering stream.

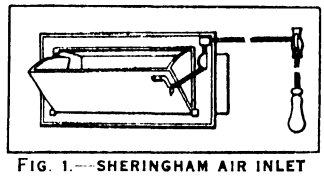

FIG. 1.—SHERINGHAM AIR INLET

In another and most valuable form of ventilator, the Tobin tube, the fresh air enters vertically upwards. The usual arrangement of Tobin tube (shown in front elevation and section in fig. 2) is a short vertical shaft of metal plate or wood which leads up the wall from the floor level to a height of 5 ft. or 6 ft.. Its lower end communicates with the outer air through an air-grating in the wall; from its upper end, which is freely open, the current of fresh air rises in a smooth stream. Various forms of section may be given to the tube: if placed in a corner it will be triangular or segmental; against a flat wall a shallow rectangular form is most usual, or it may be placed in a channel so as to be flush with the face of the wall; a lining of wood forming a dado may even be made to serve as a Tobin tube by setting it out a little way from the wall. The tube is often furnished with a regulating valve, and contrivances may be added for cleansing the entering air. A muslin or canvas bag hung in the tube, or a screen stretched diagonally across it, may be used to filter out dust; the same object is served in some degree by forcing the air, as it enters the tube at the bottom, to pass in close contact with the surface of water in a tray, by means of a deflecting plate. These complications have a double drawback: they require frequent attention to keep them in order, and by putting resistance in the way of the stream they are apt to reduce the efficiency of the ventilation. The air entering by a Tobin tube may be warmed by a coil of hot pipes within the tube or by a small gas-stove (provided, of course, with a flue to discharge outside the products of combustion), or the tube may draw its supply, not directly from the outer atmosphere, but from a hot-air flue. The opening should always be about the level of a man's head, but the tube need not extend down to the floor: all that is essential is that it should have sufficient length to let the air issue in a smooth vertical current without eddies (fig. 3). These inlets are at once so simple and effective that no hesitation need be felt in introducing them freely in the rooms of dwelling-houses. When no special provision is made for them in the walls, the advantage of a current entering vertically may still be in some degree secured by help of certain makeshift contrivances. One of these, suggested by Dr. Hinkes Bird, is to open one sash of the window a few inches and fill up the opening by a board; air then enters in a zig-zag course through the space between the meeting rails of the sashes. Still another plan is to have a light frame of wood or metal or glass made to fit in front of the lower sash when the window is opened, thus forming virtually a Tobin tube.

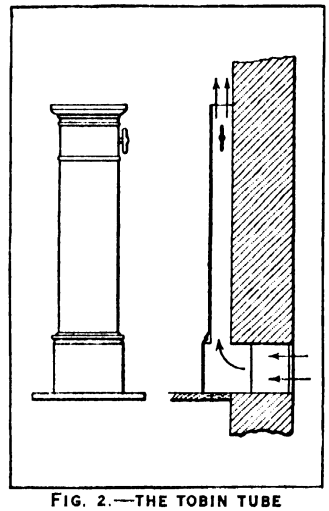

FIG. 2.—THE TOBIN TUBE

As an example of the systematic ventilation of dwelling-rooms on a large scale, the following particulars may be quoted of arrangements that have been successfully used in English barracks. One or more outlet shafts of wood fitted with flap valves to prevent down-draught are carried from the highest part of the room discharging some feet above the roof under a louvre. The number and size of these shafts are such as to give about 12 sq.in. of sectional area per head, and the chimney gives about 6 sq.in. more per head. About half the air enters cold through air-bricks or Sheringham valves at a height of about 9 ft. from the floor, and the other half is warmed by passing through flues behind the grate. The inlets taken together give an area of about 11 sq.in. per head. A fairly regular circulation of some 1,200 cu. ft. per head per hour is found to take place, and the proportion of carbon dioxide ranges from 7 to 10 parts in 10,000. In the natural ventilation of churches, halls and other large rooms we often find air admitted by gratings in the floor or near it; or the inlets may consist, like Tobin tubes, of upright flues rising to a height of about 6 ft. above the floor, from which the air proceeds in vertical streams. If the air is to be warmed before it enters, the supply may be drawn from a chamber warmed by hot-water or steam-pipes or by a stove, and the temperature of the room may be regulated by allowing part of the air to come from a hot chamber and part from outside, the two currents mixing in the shaft from which the inlets to the room draw their supply. Outlets usually consist of gratings or plain openings at or near the ceiling, preferably at a considerable distance from points vertically above the inlet tubes.

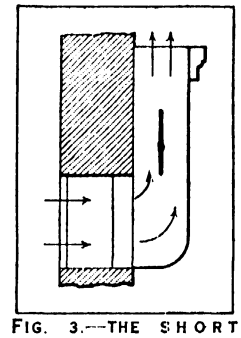

FIG. 3.—THE SHORT TOBIN TUBE

One of the chief difficulties in natural ventilation is to guard against down-draught through the action of the wind. Numberless forms of cowl have been devised with this object, with the further intention of turning the wind to useful account by making it assist the up-current of foul air. Some of these exhaust cowls are of the revolving class, made to various designs and dimensions and put in rotation by the force of the wind. Revolving cowls are liable to fail by sticking, and generally speaking, fixed cowls are to be preferred. The two things that supply motive force in automatic or natural ventilation by means of exhaust cowls and similar appliances (the difference of temperature between inner and outer air, and the wind) are so variable that even the best arrangements of inlets and outlets give a somewhat uncertain result. As an example, it is evident that on a hot day with little movement in the air this mode of ventilation would be practically ineffectual. Under other conditions these automatic air extractors not infrequently become inlets, thus reversing the whole system and pouring cold air on the heads of the inmates of the apartment or hall. To secure a strictly uniform delivery of air, unaffected by changes of season or of weather, it is necessary that the influence of these irregular motive forces be as far as possible minimized, and recourse must consequently be had to some mechanical force as a means of driving the air and securing adequate ventilation of the building. For an account of artificial ventilation *see* the article HEATING AND VENTILATING, to which a bibliography is appended.

VENTIMIGLIA (Fr. *Vintimille*, anc. *Album Intimilium* or *Albintimilium*), a frontier fortress, seaport and episcopal see of Liguria, Italy, in the province of Imperia, 94 m. W. by S. of Genoa by rail, and 4 m. from the Franco-Italian frontier, 45 ft. above sea-level. Pop. (1921) 14,125 (town), 15,805 (commune). The railway to Cuneo over the Col di Tenda (65 m.) has now been completed. The new town is important as a frontier station and for its flower market. The present Gothic cathedral is built on the ruins of an earlier Lombard church, and with the octagonal baptistery, the seminary, etc., forms a picturesque group of buildings. S. Michele is another interesting old church. Both lie in the old town, on a hill above the new. The ruins of the ancient town are situated in the plain of Nervia, 3 m. E. of the

modern. It was a *municipium* with an extensive territory, and of some importance under the Empire, but was plundered by the partisans of Otho in A.D. 69. Remains of a theatre are visible, and remains of many other buildings have been discovered, among them traces of the ancient city walls, a fine mosaic pavement and a number of tombs to the west of the theatre. The caves of the Balzi Rossi near the village of Grimaldi have proved rich in palaeolithic remains of the Quaternary period, while round Monte Bego above S. Dalmazzo di Tenda, north of Ventimiglia are numerous engravings (over 12,000) assignable to the Bronze Age. (*See* ITALY, *Prehistoric Period.*)

See P. Barocelli in *Monumenti dei Lincei* xxix. (1923–25) for a register of all discoveries; cf. also *Bollettino d'Ante*, p. 471 (1924).

VENTNOR, watering place, urban district, Isle of Wight, England, 12½ m. S. of Ryde. Pop. (1921) 6,059. It is finely situated in the Undercliff district, at the foot of St. Boniface down, which reaches a height of 787 ft. The town, built on a succession of terraces, is regarded as one of the best resorts in England for consumptives and contains several hospitals and convalescent homes. In the early 19th century it was a small fishing hamlet, but now it extends along the shore for 2 m. It has assembly rooms, a literary and scientific institution, an esplanade, a pier and extensive recreation grounds.

VENTRILOQUISM, the art of producing the voice in such a manner that it shall appear to proceed from some place altogether distant from the speaker (Lat. *venter*, belly, and *loqui*, to speak). The art of ventriloquism was formerly supposed to result from a peculiar use of the stomach (whence the name) during the process of inhalation. As a matter of fact, the words are formed in the normal manner, but the breath is allowed to escape very slowly, the tones being muffled by narrowing the glottis and the mouth opened as little as possible, while the tongue is retracted and only its tip moves. Gestures and facial expression are employed at the same time to assist in the deception by stimulating the imagination of the listeners and to distract their attention from the speaker.

Ventriloquism, which is still a recognized form of conjuring entertainment, is of ancient origin. Traces of the art are found in Egyptian and Hebrew archaeology. Eurycles of Athens was the most celebrated of Greek ventriloquists, who were called after him Eurycleides, and also *Engastrimanteis* (belly-prophets). It is not impossible that the priests of ancient times were masters of this art, and that to it may be ascribed such miracles as the speaking statues of the Egyptians, the Greek oracles, and the stone in the river Pactolus, the sound of which put robbers to flight. Many uncivilized races of modern times are adepts in ventriloquism, as the Zulus, the Maoris and the Eskimos. It is well known also in Hindustan and China.

See De la Chapelle, *Le Ventriloque, ou l'engastrimythe* (1772); E. Schultz, *Die Kunst des Bauchredens* (Erfurt, 1895); Russel, *Ventriloquism* (1898); A. Prince, *The Whole Art of Ventriloquism* (1921).

VENTSPILS, formerly Windau, a seaport and sea-bathing resort of Latvia, at the mouth of a river of the same name, on the Baltic Sea, in 57° 24′ N., 21° 32′ E. Its harbour is protected by two long breakwaters, and has ample quay space with a depth of 23 to 30 ft. There is a 45 ton electric crane and the port is ice-free all the year round. The harbour is being deepened in order to make it accessible for large ocean steamers. There is a growing transit trade with Soviet Russia. Its imports are coal and transit goods of various description and its exports timber, pit-props, butter, flax, hemp and grain. The castle dates from 1290, and the town itself from 1343.

VENTURA, a city of southern California, U.S.A., on the Pacific ocean, 2 m. from the mouth of the Santa Clara river; the county seat of Ventura county. It is served by the Southern Pacific railway and by freight steamers to San Francisco and Los Angeles. Pop. (1920) 4,342; (1928 local estimate) 18,000. It is a trading centre and shipping point for a rich agricultural region and for the neighbouring oilfields, and is the seat of the State school for girls. The city, founded in 1782, was incorporated in 1866.

VENUE, in criminal law, the proper area of jurisdiction for the trial of a crime by indictment (from the Lat. *venire*). Every criminal court has its jurisdiction limited to some part of England, and unless empowered by statute, cannot try any crimes other than those committed within its jurisdiction. For certain crimes, however, the venue may be laid in any part of England. The King's Bench Division has power to change the venue. In civil matters, that is to say, in actions commenced in the High Court, there is now no local venue for the trial of actions, but the place of trial is fixed (pursuant to Or. 36 r. 1 of the Rules of the Supreme Court) on a summons for direction, which is taken out shortly after the commencement of proceedings. As a general rule the court directs that the trial shall take place at the place which is most convenient, having regard to all the circumstances, *e.g.*, the residences of the parties and their witnesses, and the dates when assizes are held, and to the fact that jurors ought not to be asked to try cases which do not arise in their own district. (*See* further, CRIMINAL LAW; PRACTICE AND PROCEDURE; COUNTY COURTS.) (W. V. B.)

In American law jurisdiction to try crimes and civil cases must be distinguished from venue or the place where the trial may be had. Jurisdiction as between the various States is governed by common law principles of the conflict of laws. The right to enforce the judgment of one State in another State depends upon whether the former had jurisdiction of the subject matter and the parties, a fact which is always open to question by the courts of the latter State. But there being jurisdiction, the determination of the courts of the State in which the action is brought is conclusive upon the question whether the venue was properly laid. Constitutional or statutory provisions commonly govern the venue of different causes of action as between particular counties and the Federal judicial districts. Actions such as trespass to land are ordinarily triable only in the State where the cause of action arose. Most actions may be tried in any State that has jurisdiction of the parties.

VENUS (♀) is the second of the planets in order of distance from the sun. It revolves in an orbit which has the smallest eccentricity (0·007) in the planetary system, and an inclination to the ecliptic of 3° 24′. Its mean distance from the sun is 67,200,000 miles; but, whereas at inferior conjunction it is less than 26,000,000 miles from the earth, at superior conjunction it is 160,000,000 miles. The time it takes Venus to complete a revolution in its orbit is 225 days, but its synodic period, or the period of its phases, is 584 days. At its maximum elongations it recedes about 47° or 48° from the sun, so that in middle latitudes it can set or rise over 3 hours after or before the sun. When seen in the western sky in the evenings, *i.e.*, at its eastern elongations, it was called by the Ancients Ἔσπερος (Hesperus), and when visible in the mornings, *i.e.*, at its western elongations Φωσφόρος (Phosphorus). In volume and mass Venus is slightly smaller than the earth, its diameter being about 7,700 miles and its mass (deduced from its action on the earth and Mercury) 0·81 that of the earth. At superior conjunction its angular diameter is about 10″, but at inferior conjunction it exceeds 60″.

Like the earth Venus is enveloped in an atmosphere. This is shown by the fact that, near inferior conjunction, the extremely thin crescent of the visible portion of the illuminated hemisphere has often been observed to exceed 180°, while at the time of actual entry on the sun's disc during the transit of 1882, as soon as about ¼ of the planet's body was in front of the sun, the remaining portion was completely outlined by a narrow border of light. This atmosphere of Venus is apparently heavily cloud-laden, and, as the intensity of the solar radiation is almost exactly twice what it is at the earth's distance, the planet shines with a dazzling lustre, its stellar magnitude varying from −3·3 to −4·4. Its greatest brightness is attained at about 36 days on either side of inferior conjunction, its elongation from the sun then being 39°, and its phase similar to that of a 5 days old moon. When suitably situated the planet is easily visible at noonday with the naked eye, and after dark it readily casts a shadow.

As a telescopic object Venus is disappointing, since apart from the beauty of its phases it presents but few features of a definite nature. Its surface appears permanently screened from view by its cloud-laden atmosphere, and many observers have failed to

detect any markings at all upon it beyond the general fading of light near the terminator and a brightness at the cusps or other features which appear to be merely phase effects. Occasionally diffuse faint markings of a dusky character or bright areas are seen, but these are probably nothing more than inequalities in the cloudy stratum. On Feb. 13, 1913, a very definite indentation in the terminator, or line bounding the illuminated part of the disc, was observed simultaneously by McEwen of Glasgow, and Sargent at the Durham university observatory, and similar irregularities have been recorded by previous observers.

The Planet's Rotation.—In view of what has been said as to the elusive nature of the surface features, it is not surprising that the planet has been able to preserve the character of its rotation a secret to the present day. It was concluded by some of the earlier telescopic observers such as G. D. Cassini, Bianchini and Schroeter that its period is in the neighbourhood of 24 hours; but Schiaparelli (1890), after a careful study of the available material including his own observations, formed the conviction that the rotation is very slow and that it probably takes the same time as the planet's orbital revolution. This last conclusion was also arrived at by Lowell at Flagstaff. Flammarion in his review of the recorded observations considered that no reliable deduction could be drawn from them. A slow rotation would seem to be indicated by the absence of any observable ellipticity of the planet during its transits of the sun, as well as by the failure of certain spectroscopic observations to show any definite differential radial velocity at opposite sides of the visible disc. On the other hand the radiometric observations at the Mt. Wilson and Flagstaff observatories in 1922, showing a considerable amount of heat to be emitted by the dark part of the planet's disc, favour a quick rotation, as also do photographs taken in ultra-violet light by Ross at the Mt. Wilson observatory on which dusky belts are shown perpendicular to the terminator and varying from night to night. It is, however, typical of the mystery enveloping this planet that on June 26, 1927, a dark marking was photographed at Mt. Wilson which apparently remained stationary for an hour.

It may be that the harmonizing of many of the discordances referred to will ultimately be found in the theory of Professor W. H. Pickering. Observing in Jamaica in 1921, he reported observations of dusky markings indicating a rotation in approximately 68 hours about an axis which is nearly in the plane of the orbit and in line with the radius vector in heliocentric longitude 46° 7′. This result has received general support from McEwen, and it has been pointed out that the failure of the Flagstaff spectroscopic observations in 1903 to indicate rotation is explained by the fact that, on Pickering's hypothesis, the planet's pole was at that time directed towards the Earth, and that the rotation of the surface markings was accordingly almost in the plane of vision. It is to be noted that the earlier spectroscopic observations of Belopolsky at Pulkowa made under different conditions had given distinct evidence of rotation.

Habitability.—There is a point which is of considerable importance as regards the question whether Venus is fitted to be the abode of animate life. If oxygen and water vapour exist in any large quantity, we might expect their presence to be revealed by absorption lines in the spectrum of the sunlight reflected by the planet's surface. St. John, however, has found no evidence of such lines, and has concluded that the amount of oxygen above the visible surface is less than one thousandth part of the quantity in the atmosphere of the earth. It must, however, be remembered that the visible surface of Venus is apparently only that of the upper layer of a stratum of cloud, and that, although the quantities of oxygen and water vapour above this layer are apparently small, there may be considerable amounts below it. In the absence of any certain knowledge as to the planet's rotation and other important data it is not possible to form conclusions concerning its habitability, but the resemblance of Venus to the earth in size and mass, coupled with its possession of a dense atmosphere, would suggest the probability that it supports life of some kind.

Supposed Satellite.—It was at one time thought that Venus possessed a satellite, several observers in the 17th and 18th centuries reporting that they had seen it, though others searched the neighbourhood of the planet for it in vain. Observations with more perfect instruments, however, eventually demonstrated the non-existence of any such object, and it is evident that what was seen must have been the appearance of a "ghost," caused by some fault in the construction or adjustment of the instruments used.

Transits of Venus.—As is the case with Mercury, Venus, revolving round the sun inside the earth's orbit, sometimes transits the sun's face, and is seen projected on it as a small black disc. Were the planet's orbit plane coincident with that of the earth, these transits would, of course, occur at each inferior conjunction. but owing to its inclination a transit can only happen when the two planets pass near one of the nodes of Venus at about the same time, which is possible only at present in June and December. Actually a transit happens but four times in 243 years, and the intervals between transits are successively 8, 121½, 8, 105½, 8, 121½ years *et seq*, as illustrated in the following table of dates of these phenomena:

1518, June 2,	1769, June 3,
1526, June 1,	1874, Dec. 9,
1631, Dec. 7,	1882, Dec. 6,
1639, Dec. 4,	2004, June 8,
1761, June 6,	2012, June 6.

The first transit to be actually observed was that of 1639, the occurrence of the event having been calculated by Jeremiah Horrox, a young clergyman who was curate of Hoole near Preston in Lancashire. Dec. 4 in that year happened to be a Sunday, and Horrox missed seeing the beginning of the transit through having to take a service in church that afternoon, but on returning home he found to his great delight the black body of the planet clearly projected on the sun's disc.

Following on the suggestions of Edmund Halley a century later, transits of Venus were utilized for the determination of the solar parallax which gives the distance of the sun—a quantity of fundamental importance to the astronomer. Practical difficulties, however, in the observations, arising from the effect of irradiation in introducing uncertainties as to the precise moments of the internal contacts between the limbs of the sun and planet, rendered the method unsatisfactory, and far more effective ways of attacking the problem are now available for the purpose. (T. E. R. P.)

VENUS, Roman and Latin goddess, apparently representing beauty and growth in nature, and especially in gardens, where the Roman practical sense would most naturally see these. She had two temples in Rome, one in the grove of Libitina, with whom she was wrongly identified, and the other near the Circus Maximus, both of which had as their dedication day Aug. 19, the festival of the *Vinalia rustica*, a fact which also points in the direction of skilled cultivation as the human work of which she was protectress. But this old Latin deity was in historical times entirely absorbed by the Greek Aphrodite, and assumed the characteristics of a cult of human love, which in her original form she had never possessed. *See* APHRODITE.

VENUSIA (mod. *Venosa, q.v.*), an ancient city of Apulia, Italy, on the Via Appia, about 6 m. S. of the river Aufidus (Ofanto), and near the boundary of Lucania. It was taken by the Romans after the Samnite war of 291 B.C., and became a colony at once, no fewer than 20,000 men being sent there, owing to its military importance. The site is a specially strong one, being almost isolated by two deep ravines. Throughout the Hannibalic wars it remained faithful to Rome, and had a further contingent of colonists sent in 200 B.C. to replace its losses in war. It took part in the Social War, and was recaptured by Quintus Metellus Pius; in 43 B.C. its territory was assigned to the veterans of the triumvirs. Horace was born here, the son of a freedman, in 65 B.C. It remained an important place under the Empire as a station on the Via Appia. Jewish catacombs with inscriptions in Hebrew, Greek and Latin show the importance of the Jewish population here in the 4th and 5th centuries A.D.

VENUS'S FLY-TRAP, a remarkable insectivorous plant (*Dionaea muscipula*) of the family Droseraceae, a native of North and South Carolina, first described in 1768 by the American botanist Ellis, in a letter to Linnaeus, in which he gave a substantially correct account of the structure and functions of its

leaves, and even suggested the probability of their insectivorous habit. Linnaeus declared it the most wonderful of plants (*miraculum naturae*), yet only admitted that it showed an extreme case of sensitiveness, supposing that the insects were only accidentally captured and subsequently allowed to escape. The insectivorous habit of the plant was subsequently fully investigated and described by Charles Darwin in his book on insectivorous plants.

The plant is a small herb with a rosette of radical leaves with broad leaf-like footstalks. Each leaf has two lobes, standing at rather less than a right angle to each other, their edges being produced into spike-like processes. The upper surface of each lobe is covered with minute circular sessile glands. It bears also three fine-pointed sensitive bristles. These contain no fibro-vascular bundles, but show a constriction near their bases, which enables them to bend parallel to the surface of the leaf when the lobes close. When the bristles are touched by an insect the lobes—after a latent period of less than a second under suitable temperature conditions—close upon the hinge-like midrib, the spikes interlock, and the insect is imprisoned.

The leaf then forms itself into what may be called a temporary stomach, and the glands, hitherto dry, are stimulated by the presence of chemical substances passing out of the insect to pour out an acid secretion containing an enzyme (*q.v.*), similar to that excreted by the leaves of the sundew, which rapidly dissolves the soft parts of the insect. This is produced in such abundance that, when Darwin made a small opening at the base of one lobe of a leaf which had closed over a large crushed fly, the secretion continued to run down the footstalk during the whole time—nine days—during which the plant was kept under observation. The closing of the leaf is due to alterations in the cell-structure of the leaf and is later fixed by growth. The closing is accompanied by electrical changes which have been compared with those occurring in stimulated muscle.

Though the bristles are exquisitely sensitive to the slightest contact with solid bodies, yet they are far less sensitive than those of the sundew (*Drosera*) to prolonged stimulation, a singular relation of the habits of the two plants. Like the leaves of *Drosera*, however, those of *Dionaea* are completely indifferent to wind and rain. The surface of the blade is very slightly sensitive; it may be roughly handled or scratched without causing movement, but closes when its surface or midrib is deeply pricked or cut. After the absorption of the products of digestion of the insect the leaf opens again by a process of growth and is ready for another meal. *Dionaea* and *Mimosa* show the two most striking cases of movement in the plant kingdom.

For further details *see* C. Darwin, *Insectivorous Plants* (1875); M. Shene, *Biology of Flowering Plants* (1924).

VENUS'S LOOKING GLASS, a popular garden name for *Specularia Speculum* (or *Campanula Speculum*), from the old Latin name for the plant, *Speculum Veneris*. It is a common cornfield plant in the south of Europe, and is grown in gardens on account of its brilliant purple flowers. In North America four native species occur, of which the American Venus's looking-glass or clasping bell-flower (*S. perfoliata*) and the small Venus's looking glass (*S. biflora*) are found across the continent, the latter extending to South America.

VERACRUZ (officially VERACRUZ LLAVE), a Gulf Coast State of Mexico, bounded north by Tamaulipas, west by San Luis Potosi, Hidalgo, Puebla and Oaxaca, and south-east by Chiapas and Tabasco. Pop. (1900) 981,030; (1910) 1,132,459. It is about 50m. wide, extending along the coast north-west to south-east, for a distance of 435m., with an area of 29,201 square miles. It was the seat of an ancient Indian civilization antedating the Aztecs and is filled with remarkable and interesting ruins; it is now one of the richest States of the republic. It consists of a low, sandy coastal zone, much broken with tidewater streams and lagoons, behind which the land rises gradually to the base of the sierras and then in rich valleys and wooded slopes to their summits on the eastern margin of the great Mexican plateau, from which rise the majestic summits of Orizaba and Cofre de Perote. The climate is hot, humid and malarial, except on the higher elevations; the rainfall is heavy, and the tropical vegetation is so dense that it is practically impossible to clear it away. At Coatzacoalcos the annual precipitation ranges from 125 to 140in., but it steadily decreases towards the north. On the higher slopes of the sierras prehistoric terraces are found, evidently constructed to prevent the washing away of the soil by these heavy rains. More than 40 rivers cross the State from the sierras to the coast. There are several ports on the coast—Coatzacoalcos, Alvarado, Veracruz, Nautla, Tecolutla and Tuxpam. The products of the State are chiefly agricultural—cotton, sugar, rum, tobacco, coffee, cacao, vanilla, maize, beans and fruit. Cattle-raising is followed in some districts, cattle and hides being among the exports. Among the forest products are rubber, cabinet woods, dye-woods, broom-root, chicle, jalap and orchids. Veracruz is one of the largest producers of sugar and rum in Mexico. There are a number of cotton factories (one of the largest in Mexico being at Orizaba), chiefly devoted to the making of coarse cloth for the lower classes. Tobacco factories are also numerous. Other manufactures include paper, chocolate, soap and matches. There are four lines of railway converging at Veracruz, two of which cross the State by different routes to converge again at Mexico City. Another, the Tehuantepec National railway, crosses in the south, and is connected with Veracruz (city) by the Veracruz and Pacific line, which traverses the State in a south-easterly direction. The capital is Jalapa, and the principal towns are Veracruz, Orizaba, Cordova and Coatzacoalcos.

VERACRUZ, a city and seaport of Mexico, in the State of Veracruz, on a slight indentation of the coast of the Gulf of Mexico, in 19° 11′ 50″ N., 96° 20′ W., slightly sheltered by some small islands and reefs. Pop. (1910) 53,115. Veracruz is the most important port of the republic. It is 263 m. by rail E. of the city of Mexico, with which it is connected by two lines of railway. It is built on a flat, sandy, barren beach, only a few feet above sea-level. The harbour is confined to a comparatively narrow channel inside a line of reefs and small islands, which is exposed to the full force of northern storms. New port works were completed towards the end of the 19th century, which, by means of breakwaters, afford complete protection. In 1905 the four railway companies having terminal stations in Veracruz united in the organization of a joint terminal association, with union station, tracks, warehouses, quays, cranes, etc.

Veracruz dates from 1520, soon after the first landing there of Cortes. This settlement was called Villa Rica de Veracruz, but was soon after moved to the harbour of Bernal, in 1525 to a point now called Old Veracruz, and in 1599 to its present site. It was pillaged by privateers in 1653 and 1712, and this led to the erection of the celebrated fort of San Juan de Ulúa, or Ulloa, on one of the reefs in front of the city. In 1838 it was captured by the French, on March 29, 1847 by an American army under Gen. Winfield Scott, who made Veracruz a base for his march upon the City of Mexico, and in 1861 by the French. Felix Díaz, nephew of President Díaz, captured Veracruz on Oct. 15, 1912, in a revolt against the Madero Government. Surprised by Federal troops, he was taken prisoner on Oct. 22, and interned in Ulúa fort.

Naval forces of the United States landed in Veracruz on April 21, 1914, seized the port and thereby brought about the resignation of President Huerta. They held the city until Nov. 23, 1914.

VERATRINE (Cevadine), the most important and the most toxic of a series of alkaloids (*q.v.*) obtained from sabadilla seeds (Merck, 1855). The name veratrine has been applied so variously that the synonym cevadine was introduced by Wright and Luff (1878) to distinguish the pure alkaloid (crystallized veratrine) which crystallizes from warm diluted alcohol in colourless rhombic prisms, melts at 205° C, and has a specific rotation $[\alpha]_D+12{\cdot}5°$. Cevadine, $C_{32}H_{49}O_9N$, forms a series of well-crystallized salts and behaves as an ester, being hydrolyzed to tiglic acid and the basic alcohol *cevine*, $C_{27}H_{43}O_8N$, which is much less toxic than the parent alkaloid. In physiological action veratrine has affinities with the even more poisonous alkaloid aconitine.

VERATRUM. The Greek physicians were acquainted with a poisonous herb which they called white hellebore, and which has been supposed to represent the *Veratrum album* of modern botanists. In modern times the name has been applied to a genus of herbaceous plants belonging to the family Liliaceae. *Veratrum* is a tall-growing herb, having a fibrous root-stock, an erect stem, with numerous broad, plicated leaves placed alternately, and terminal, much-branched clusters of greenish or purplish polygamous flowers. Each perfect flower consists of six regular petals, as many stamens, whose anthers open outwardly, and a three-celled superior ovary which ripens into a three-celled, many-seeded capsule. The genus comprises 10 species, natives of the temperate regions of the northern hemisphere, generally growing in pastures or woods. *V. album* and the North American species *V. viride* are commonly grown in gardens as ornamental perennials, but their poisonous qualities should be kept in mind, particularly as they bear a considerable resemblance in foliage to the harmless *Gentiana lutea*. Both contain the potent alkaloid veratrine. (*See* also HELLEBORE.)

VERBENA. The genus *Verbena* (vervain) in botany gives its name to the family (Verbenaceae), of which it is a member. The species are herbaceous or somewhat shrubby, with opposite or whorled leaves, generally deeply cut. The sessile flowers are aggregated into close spikes. Each flower has a tubular, ribbed calyx, a more or less irregular tubular two-lipped corolla, with four (didynamous) stamens springing from the interior of the corolla-tube. The anthers are two-celled. The ovary is entire or four-lobed, and always four-celled, with a single ovule in each cell. The fruit consists of four hard nutlets within the persistent calyx. There are about 100 species, mostly natives of tropical and subtropical America, some 20 being native to the United States, a very few species occurring also in the Old World. The garden verbenas are mostly derivatives from a few South American species, such as *V. teucrioides*, of southern Brazil, and *V. chamaedrifolia* from Argentina and southern Brazil. Various cultivated forms have been derived also from the North American *V. canadensis*. The range of colours extends from pure white to rose-coloured, carmine, violet and purple. Striped forms also are cultivated. The lemon-scented verbena of gardens, much valued for the fragrance of its leaves is now referred to the genus *Lippia* as *L. citriodora;* it differs from *Verbena* in having two, not four, nutlets in the fruit.

The garden verbenas are easily raised from seeds sown in heat in February or March, but choice varieties can only be kept true when raised from cuttings. These are best secured from old plants cut down in the autumn and started into growth in gentle heat and moisture the following spring. They root readily in a compost of sandy loam. (*See* VERBENACEAE; VERVAIN.)

VERBENACEAE, a family of dicotyledonous plants, comprising about 70 genera and some 750 species of herbs, shrubs and trees, nearly all tropical and subtropical. Vervain (*q.v.*) is British. *Lippia* and *Cymbopogon* yield verbena oil and several species, as teak (*Tectona grandis*), supply useful timber. Many are lianes. Some species bear thorns; others are xerophytic. Numerous species are cultivated for ornament, as the verbena (*q.v.*), chaste-tree (*Vitex Agnus-castus*), glory-bower (*Clerodendrum*), purple wreath (*Petraea volubilis*), golden dewdrop (*Durantia repens*), bluebeard (*Caryopteris incana*) and French mulberry (*Callicarpa americana*).

VERBOECKHOVEN, EUGÈNE JOSEPH (1798–1881), Belgian painter, was born at Warneton in West Flanders on June 9, 1798, and received instruction in drawing and modelling from his father, the sculptor Barthélemy Verboeckhoven. His paintings of sheep, of horses and of cattle in landscape, somewhat after the manner of Potter, brought him universal fame, and were eagerly sought for by collectors. Precise and careful finish is the chief quality of his art, which is entirely objective and lacking in inspiration. Verboeckhoven visited England in 1826, Germany in 1828, and France and Italy in 1841. He died in Brussels on Jan. 19, 1881. Examples of his art are to be found in nearly all the important galleries of Europe and the United States, notably in Brussels, Antwerp, Amsterdam, Hamburg, Berlin, Munich, New York, Boston and Washington. In addition to his painted work he executed some 50 etched plates of similar subjects.

VERCELLI (anc. *Vercellae*), a provincial capital and archiepiscopal see of Piedmont, Italy, in the province of Novara, 13 m. S.W. of that town by rail. Pop. (1921): 29,009, town; 32,769, commune. It is situated 430 ft. above sea-level on the river Sesia, at its junction with the Canterana. Vercelli is a point at which railways diverge for Novara, Mortara, Casale Monferrato and Santhià (for Turin). The Piazza Cavour has a statue of Cavour. The cathedral library contains many ancient mss., especially the *Codex Vercellensis* (*see* VERCELLI BOOK). The church of S. Andrea is a Romanesque Gothic building of 1219–24, with lofty towers and an interior in the French Gothic style and a museum of Roman antiquities in the adjacent cloister. S. Paolo, S. Francesco and S. Cristoforo possess valuable examples of the work of Gaudenzio Ferrari (1471–1546) and of his follower Lanini. The castle of the Visconti is now a prison. Vercelli was the birth place of the painter Giovanni Antonio Bazzi, called Sodoma (1477–1549). Vercelli is one of the principal Italian centres of the exportation of cereals and especially of rice.

Vercellae, originally the chief city of the Libici (a Ligurian tribe), was at the junction of Roman roads to Eporedia, Novaria and Mediolanum, Laumellum (for Ticinum) and perhaps Hasta. Remains of the theatre and amphitheatre were seen in the 16th century, and ancient streets have been traced during drainage operations. In the neighbourhood (near Rotto on the Sesia) are the Raudii Campi where Hannibal won his first victory on Italian soil (218 B.C.), and where in 101 B.C. Marius and Catulus routed the Cimbri. From about 1228 till 1372 Vercelli was the seat of a university. (T. **A.**)

VERCELLI BOOK (CODEX VERCELLENSIS), an O.E. ms. containing, besides homilies, *Andreas, Fates of the Apostles, Address of the Soul to the Body, Falseness of Men, Dream of the Rood, Elene* and a prose *Life of Guthlac,* found in the cathedral library of Vercelli, by Blume in 1822, and described in his *Iter Italicum* (Berlin and Stettin, 1824–36). The hand-writing dates from the beginning of the 11th century. According to Wülker the ms. probably belonged to the hospice for English pilgrims, founded by Cardinal Guala (d. 1227), a native of Vercelli and bishop of the city, in 1219, on his return from England, where he had been papal legate. The cardinal possessed a large library, which he left to the monastery; and the Vercelli codex may well have been included in it.

Its contents were partially printed (by Thorpe from Blume's transcript) in Appendix B to Cooper's *Report of Rymeri Foedera* for 1836; by Kemble, *Poetry of the Codex Vercellensis* (Aelfric Soc., 1843–56), and in a text based directly on the ms. by Wülker in his edition of Grein's *Bibliothek der A.S. Poesie* (Leipzig, 1894). *Codex Vercellensis,* by Wülker (Leipzig, 1894), is a facsimile.

For the description and history of the ms. *see* also R. Wülker, *Grundriss der A.S. Litteratur* (1885), pp. 237–42, and A. Napier in *Zeitschrift für deutsches Altertum* (1889, vol. 21, new series; old series, vol. 33, p. 66). *See* also CYNEWULF.

VERCINGETORIX (*ob.* 45 B.C.), Gaulish chieftain, waged war with ability against Caesar in 52 B.C. For the history of the campaign *see* CAESAR. He fell into Caesar's hands at the capture of Alesia, was exhibited at Caesar's triumph in 45 and was then put to death.

See Caesar, *B.G.* VII.

VERDEN, a town in the Prussian province of Hanover, on the navigable Aller, 3 m. above its confluence with the Weser, 22 m. S.E. of Bremen by the railway to Hanover. Pop. (1925) 10,048. Verden was the seat of a bishopric founded in the first quarter of the 9th century, or earlier, and secularized in 1648. The duchy of Verden was then ceded to Sweden, passed in 1719 to Hanover and was, with Hanover, annexed by Prussia in 1866. The most noticeable edifice is the Gothic cathedral. Its industries embrace the manufacture of furniture, soap and machinery, cigar-making, brewing and distilling.

VERDI, GIUSEPPE FORTUNINO FRANCESCO (1813–1901), Italian composer, was born on Oct. 10, 1813, at Le Roncole, near Busseto. His parents kept a little inn, combined with a kind of village shop. Verdi's musical education really began with his entrance into the house of business of Antonio Barezzi, a merchant of Busseto, who was a thorough musician.

He studied under Provesi, *maestro di cappella* of the cathedral and conductor of the municipal orchestra, for which Verdi wrote many marches, and other instrumental pieces. His first symphony was written at the age of fifteen and performed in 1828. In 1832 Verdi went to Milan to complete his studies. He was rejected by the authorities of the Conservatorio, but remained in Milan as a pupil of Vincenzo Lavigna, with whom he worked until the death of Provesi in 1833 recalled him to Busseto. A clerical intrigue prevented him from succeeding his old master as cathedral organist, but he was appointed conductor of the municipal orchestra, and organist of the church of San Bartolomeo. After Verdi's return to Milan, his first opera, *Oberto, Conte di San Bonifacio,* was produced in 1839. His next work, a comic opera, known variously as *Un Giorno di Regno* and *Il Finto Stanislao,* and composed in peculiarly distressing circumstances (the young composer had just lost his wife and two children) was a complete failure, and Verdi, stung by disappointment, determined to write no more for the stage. But a year later Merelli, the impresario of La Scala, persuaded him to write *Nabucodonosor* (1842), which placed him in the front rank of living Italian composers. *I Lombardi* (1843) and *Ernani* (1844) followed. With *Ernani* Verdi became the most popular composer in Europe, and the incessant demands made upon him reacted upon his style.

Macbeth (1847), *Luisa Miller* (1849) and *I Masnadieri,* produced at Her Majesty's Theatre in 1847, did not enhance his reputation, but in *Rigoletto* (1851), *Il Trovatore* (1853) and *La Traviata* (1853) Verdi reached the culminating point of what may be called his second manner. *Les Vêpres Siciliennes* (1855), written for the Paris Opéra contains some fine music, but suffers from the composer's perhaps unconscious attempt to adopt the grandiose manner of French opera. Of the works written during the next ten years only *Un Ballo in Maschera* (Rome, Feb. 17, 1859) has maintained a fitful hold upon public attention. *La Forza del Destino* (Nov. 10, 1862, St. Petersburg) and *Don Carlos* (March 11, 1867, Paris) are transitional works.

At this point in his career Verdi was preparing to emancipate himself from his early conventions, and was struggling towards a freer method of expression. In *Aïda* (Dec. 1871, Cairo) an opera upon an Egyptian subject, written in response to an invitation from Ismail Pasha, Verdi entered upon the third period of his career. In this work he broke definitely with the operatic tradition inherited from Donizetti, in favour of a method of utterance, which, though perhaps affected in some degree by the influence of Wagner, still retains the main characteristics of Italian music. In *Aïda* the treatment of the orchestra shows a richness of resource which those who knew only Verdi's earlier works scarcely suspected him of possessing; while its wealth of melody, massive ensembles, picturesque local colour, and other attractive qualities have long since established the work among the most successful and popular operas ever written. In the *Requiem,* written in 1874 to commemorate the death of Manzoni, Verdi applied his newly found system to sacred music. His *Requiem* was bitterly assailed by pedants and purists, partly on the ground of its defiance of obsolete rules of musical grammar and partly because of its theatrical treatment of sacred subjects, but by saner and more sympathetic critics, of whom Brahms was not the least enthusiastic, it has been accepted as a work of genius. In 1881 a thoroughly revised version of *Simon Boccanegra* was successfully produced at Milan.

In 1887 (Feb. 5) *Otello* was produced at Milan when Verdi was nearly seventy. The libretto, from Shakespeare's *Othello,* was the work of Boito. *Otello* recalls *Aïda* in the general outlines of its structure, but voices and orchestra are treated with greater freedom than in the earlier work, and there are no set arias. *Otello* is, musically and dramatically, an immense advance upon anything Verdi had previously written; and no less applies to *Falstaff,* which was produced at Milan on Feb. 9, 1893, when the composer was in his eightieth year, and which contains, besides the dramatic power and musical skill of *Otello,* a fund of delicate and fanciful humour which recalls the gayest mood of Mozart.

Falstaff was Verdi's last work for the stage but in 1898 he produced four beautiful sacred pieces, settings of the *Ave Maria, Laudi alla Virgine* (words from Dante's *Paradiso*), the *Stabat Mater* and the *Te Deum,* the first two for voices alone, the last two for voices and orchestra. Of his other minor and non-dramatic works, very few in number, may be mentioned a string quartet, composed in 1873, a hymn written for the opening of the International Exhibition of 1862, two sets of songs, a *Paternoster* for five-part chorus, and an *Ave Maria* for soprano solo, with string accompaniment. He died at Milan on Jan. 27, 1901.

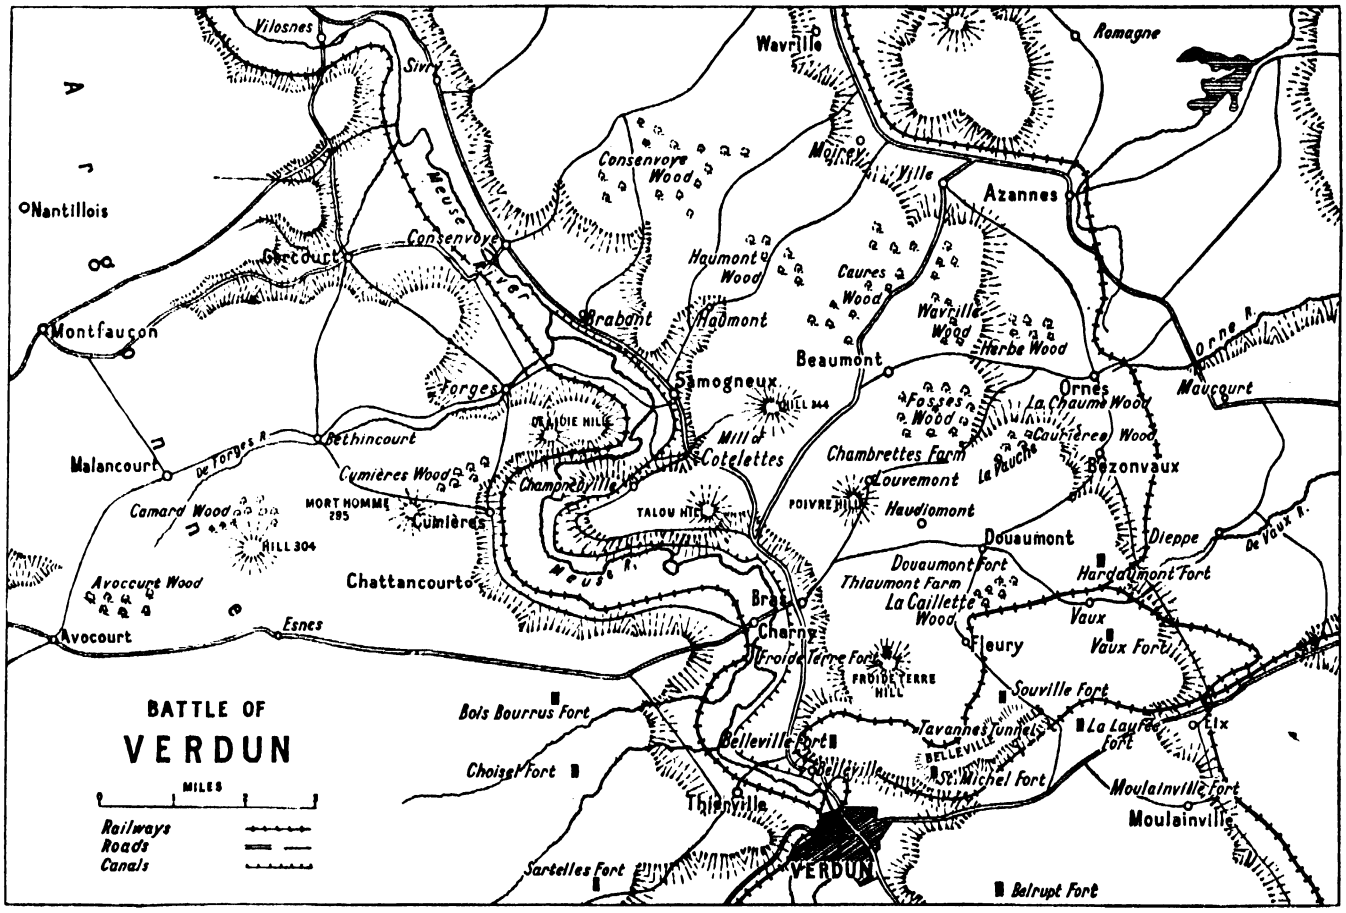
VERDIGRIS is a basic copper acetate of varying composition. Dissolved in pine balsam, it formed one of the permanent greens of the Middle Ages. Owing to its behaviour as an oil colour (turning from dark green to black) and as a water colour (fading), it is replaced as a pigment by the more permanent chromium and cobalt greens and is now used mainly in anti-fouling compositions and wood preservatives. It is an irritant poison; the best antidote is white of egg and milk. *See* PAINTS, CHEMISTRY OF.



VERDUN, a garrison town of north-eastern France, capital of an arrondissement in the department of Meuse, on the main line of the Eastern railway between Paris and Metz, 42 m. N.N.E. of Bar-le-Duc. Pop. (1926) 12,651.

Verdun (*Verodunum*), an important town at the time of the Roman conquest, was made a part of Belgica Prima. The bishopric, held by St. Vanne (498–525), dates from the 3rd century. Verdun was destroyed during the period of the barbarian invasions, and recovered only at the end of the 5th century. Clovis seized the town in 502, and it afterwards belonged to the kingdom of Austrasia. In 843 the famous treaty was signed here by the sons of Louis the Pious. (*See* GERMANY: *History.*) In the 10th century Verdun was conquered by Germany and put under the temporal authority of its bishops. Together with Toul and Metz, the town and its domain formed the territory of the Trois-Évêchés. In the 11th century the burghers began a struggle with their bishops, which ended in their obtaining certain rights in the 12th century. In 1552 Henry II. of France took possession of the Trois-Évêchés, which finally became French by the Treaty of Westphalia. In 1792, the citizens opened their gates to the Prussians. In 1870 the Prussians invested and bombarded it three times, till it capitulated in the beginning of November. (For the part played by Verdun in the World War of 1914–18 *see* WORLD WAR.) It was the greatest centre of resistance to the German invasion and advances of 1914–18, and was reduced to ruins as a result. (*See* VERDUN, BATTLES OF.)

Verdun stands on the Meuse, here canalized, and was a great fortress. The chief quarter of the town lay on the slope of the left bank of the river and was dominated by the citadel which occupied the site of the old abbey of St. Vanne founded in the 10th century. The whole town was surrounded by a bastioned enceinte, pierced by four gates; that to the north-east, the Porte Chaussée, 15th–17th century, with two crenelated towers, was little damaged in the war of 1914–18. The cathedral of Notre-Dame in process of restoration, stands on the site of two previous churches of the Romanesque period, the first of which was burnt down in 1047. There are double transepts and, till the 18th century when the western apse was replaced by a façade, there was an apse at each extremity. To the south-west of the cathedral is a fine 15th century cloister. The *hôtel-de-ville* (17th century) has been restored.

VERDUN, BATTLES OF. The invader of France coming from the east is confronted by a series of ridges between the Moselle and Paris. The second of these ridges is formed by the historic escarpment 400 metres in height, above the Meuse and called the Heights of the Meuse. Here is placed the fortress of Verdun, one of the main barriers on the road to Paris. It was the primary objective of the German campaign of 1916, and the failure to secure it had a far-reaching influence on the course of the World War.

History of the Fortress.—After the war of 1870 Gen. Séré de

Rivière, who was entrusted with the task of organising the frontier defences, constructed a protective curtain stretching from Verdun on the north to Toul on the south. Fortresses guarded the routes between these two places. On this rampart of the Heights of the Meuse Verdun formed the northern muzzle, opposite the fortified camp at Metz some 40 m. away. The fortress was planned so that the principal line of resistance faced north. Inside the two lines of forts was an old fortified enclosure of Vauban's time and a citadel dating back to Henry II. Galleries hewn out of the rocky foundation of the citadel, with workshops, bakeries, stores of food, water pumps and barracks formed a subterranean city safe against bombardment.

Verdun in 1914.—At the beginning of the War the fortress was an independent command. After the battle of the Frontiers the III. Army in retreat pivotted its right upon it as a breakwater against the German tide of advance, which turned on Sept. 13, 1914, by reason of the defeat of the German armies before Paris. (*See* MARNE, FIRST BATTLE OF.) The French lines were then established 10 km. north of Verdun and the sector was quiet for nearly 18 months. South-east of Verdun a stiff but indecisive fight took place in the spring of 1915 for the observatory of Les Eparges, and further south, in the area of St. Mihiel, by a surprise attack on Sept. 20, 1914 the Bavarians drove in a wedge and gained a foothold on the left bank of the Meuse. This wedge remained in the French front, a potential menace, until the American attack of Sept. 12, 1918. (*See* ST. MIHIEL, BATTLE OF.) West of Verdun the Crown Prince attempted to reach the Argonne in the direction of Varennes and forced the French lines back to the edge of Boureuilles and Vauquois.

The autonomy of the great fortresses was cancelled on Aug. 5, 1915 in order to make their garrisons and equipment available for the armies in the field. Dunkirk, Verdun and Belfort, the three great fortresses on the area of battle, became fortified regions linked up with the armies. The fortified region of Verdun (R.F.V.) was placed under Gen. Herr, who ranked as an army commander. The R.F.V. was on Feb. 1, 1916 attached to the group of Armies of the Centre—then commanded by Gen. Langle de Cary. On Feb. 10, 1916 Gen. Herr had available seven divisions with one in reserve, and two territorial brigades.

Germany Selects Verdun for Attack.—About Christmas 1915 Gen. von Falkenhayn submitted to the German Emperor a report setting forth the views of the German Staff as to the campaign of 1916. The report urged that France had reached the limits of exhaustion. Russia was powerless, Serbia destroyed, Italy deceived, though all were sustained by the will of Britain who was fighting against Germany as she had fought against Napoleon. Unfortunately it was not easy to reach Britain effectively either in her distant possessions by operations which could never be decisive, or on her own soil, or on the Continent. It was impossible to attack Britain directly. But she would be defeated if the Allied armies on the Continent were broken.

Where, then, was this to be done? Defeat of Italy would have little effect on England. Operations against Russia could not begin till April and then only towards the Ukraine where communications were lacking and a flank would be exposed to Rumania. The only possible line of attack was against France. It was not necessary to attack or break through in force. Behind, but close to, the French front were positions of such importance that they would have to be held to the last man. This reasoning led to the battle of Verdun. The German Command sought to force the French to accept battle under conditions of forced defence—conditions which are fatal to the defender.

The two objectives which realised Falkenhayn's conditions were Belfort and Verdun. The capture of Belfort involved the evacuation by the French of Upper Alsace. Verdun, however, was important for three reasons. From Verdun the French could launch an attack, similar to that contemplated by the Germans, upon the German communications. "Verdun," said Falkenhayn's report, "is the strongest starting point for any attempt by the enemy to threaten the whole German front in France and Belgium with relatively small forces." The French lines were but 12 m. from the German communications. Throughout the War German headquarters dreaded an Allied attack starting from Verdun.

An attack on Verdun had been foreseen by some on the French side. Col. Driant, Deputy for Nancy, who commanded a group of chasseurs in the fortified region of Verdun, wrote to the Minister for War that the decisive blow would be struck on the line Verdun-Nancy. The defensive organization of Verdun was incomplete. Gen. Herr, by the instructions of Aug. 9, 1915, had to link up the III. Army in Argonne with the I. Army in the Woëvre. That involved the revision of the defensive system of the fortress from a circular scheme to one of a series of parallel and successive lines. But the Commander-in-Chief, disturbed by the thrust of the Germans in the Argonne, also ordered Gen. Herr to prepare a defensive position on the left bank in case Verdun had to be abandoned. Gen. Herr could not manage this double programme with his resources and of four positions suggested on the right bank, only the first existed at the end of Jan. 1916.

On Dec. 3 Col. Driant was in Paris and communicated his views to his colleagues on the Commission of the Army. Gen. Pedoya, President of the Commission, passed the warning to Gen. Gallieni, the Minister for War, who wrote on Dec. 16 to Marshal Joffre inquiring whether all along the front a defensive system of at least two lines had been planned and carried out with such constructional features as were necessary in support. On the 18th Joffre replied somewhat confusedly and stated that the improvement of the double line system already existing along the whole front had been ordered on Oct. 22, that the organization of the fortified areas in the rear of the armies had also been ordered, and that this combination of defensive measures was in process of completion and at a number of points had been completed.

Gallieni replied on the 22nd that the Government hoped that the works still to be completed would be carried out with all speed and care and that the Government had full confidence in the Commander-in-Chief. In order to conceal its plans about Verdun the German Supreme Command arranged to carry out preliminary measures at several points on the front. The French Staff was for long in doubt whether the attack would come in Artois or in Champagne. But from Jan. 1916 French airmen reported enemy preparations on the Verdun front. On Jan. 16 Gen. Herr collected all this information in a formal report and asked for a division to reinforce him. This was sent to him.

I. THE GERMAN OFFENSIVE

On Feb. 8, 1916 it was discovered that the Germans had brought a mass of manoeuvre to the neighbourhood of Verdun. A deserter disclosed the presence of two corps. On the 11th an intelligence officer reported a concentration of troops on the east bank of the Meuse. The French Command at once took precautions. On Feb. 13 three divisions of the VII. Corps (14th, 37th and 48th) were moved to Souilly, a march south of Verdun, followed on the 16th by two divisions of the XX. Corps. On the 20th the Commander-in-Chief, who had inspected this front on the 19th, ordered the I. Army to place the 16th Div. at Gen. Herr's disposition, thus completing the XX. Corps.

French Supply Problems.—Transport questions arose. Ordinarily two standard gauge railways serve Verdun. The southern line had been cut by the enemy. The western line would be, and was, cut as soon as operations started. A departmental railway, the Meusien line, and a road from Bar-le-Duc still remained. To maintain supplies for an engagement in which 15 or 20 divisions are engaged, the daily requirements are 2,000 tons of munitions, 100 tons of supplies and material for each division, say 2,000 tons, and from 15,000 to 20,000 men. The Meusien Railway at best carried 800 tons daily. On the 19th Capt. Doumenc, commanding the M.T. service, undertook to carry 2,000 tons and 12,000 men daily in lorries provided that the M.T. service had sole control over the roads. Motor traffic was organized on the 20th on railway lines. From the 29th, 3,000, later 3,500, lorries passed in an endless stream along this little road only seven yards wide; 6,000 vehicles passed a given point in 24 hours, an average frequency of one vehicle every 14 seconds. At times the traffic rose to one vehicle every five seconds. In the language of the War this road was known as the "Sacred Way."

German Dispositions.—Verdun was confronted by the German V. Army—part of the command of the Crown Prince, who directed the offensive. The Germans had 26 divisions available on the Western Front. A third of these were kept as a general reserve; 17 to 18 divisions were therefore available for the Verdun attack. The German Command allotted nine divisions to the first attack, which started from the east bank. East of the Meuse was the VII. Res. Corps (one division in line, one in support); then the XVIII. Corps and the III. Corps in echelon of divisions. Farther east the XV. Corps was held in the plain of the Woëvre, ready on the breach of the French front to hurl itself on the French flank. The 113th Div., completing the assault troops, was in support. This mass of manoeuvre had been embodied in the Crown Prince's Army command and to make way for it, room was made between the V. Res. Corps and the VI. Res. Corps. The duty of the latter, on the west bank of the Meuse, was to attack the French when broken on the east bank and to bar their retreat. Thus it was engaged only on March 6.

On Feb. 21, 1916, at 7.15 A.M. the Germans commenced bombardment on a front of 25 m. from the Bois d'Avocourt to Étain. It was of unheard of intensity. Heavy shell were used in vast quantities. The woods were full of guns which fired ceaselessly with measured regularity. Observers from the air ceased to mark batteries on the map. The woods to them were masses of clouds pierced by flashes of lightning. Soon the French squadrons were chased from the sky.

The Attack Opens.—About 4.15 P.M. the first infantry attack was launched. Commandant Vouvard remarks that "It is probable that there were strong reconnoitring parties to test the efficacy of the artillery preparations and to seize trenches which had been destroyed. Beyond doubt that first day the Germans sought to put their infantry in an advantageous position and to get into line for the battle of the next day, by making it pass even the unequal intervals separating the lines." As a fact, the Germans, to effect a surprise, had not dug parallels from which to issue and moved from their lines at distances from the French lines which varied from 600 to 1,100 metres. Gillet describes their new tactics thus: "Each troop had a specific task, with an objective of limited breadth and depth. Before taking hold of it, a wave of scouts was sent forward to test the destruction by the artillery fire. If the destruction were not thorough the scouts retired and further artillery preparation was organised. The attack took place in waves about 80 metres apart. First came a line of pioneers and men with bombs. Then came the main body in single file. Then followed a reserve section carrying up ammunition, tools, sandbags, and filling up gaps in the first wave. A second line followed in the same order, passing through the first line, supporting it if checked and renewing the assault on their own initiative. The attack should now proceed by encircling movements, utilising cover and passing along ravines. Thus the centres of resistance would fall one by one. Shell fire would support the advance continually. On no account should troops attempt to overcome resistance which has not been broken by artillery fire. Units when held up must wait for fresh artillery action."

Early German Successes.—The French line rested on the village of Brabant, then on the Bois de Consenvoye, Bois d'Haumont, Bois de Caures, Bois de Ville and on Herbebois. A little in the rear the Bois de La Wavrille (southeast of the Bois de Ville) and the village of Beaumont had been strengthened with redoubts. On the extreme right the line rested on the village of Ornes. Before the German attack, what remained of the French trenches was filled with defenders. At Herbebois the Germans captured the first lines but were stopped in front of the supporting trenches. The Bois de Caures was lost but its northern part was retaken during the night. The loss of the Bois d'Haumont was a serious matter. A French counter-attack on the 22nd at 6 A.M. failed. The line had been pierced.

The Germans made good use, on the 22nd, of the advantage gained at the Bois d'Haumont. The village of Haumont was destroyed by shell fire and at 5.00 P.M. was attacked by three columns. The main redoubt, built of concrete, collapsed and buried 80 men. The remaining defenders were hunted from the cellars by bombs and liquid fire but rallied at Samogneux. Bois de Ville

was lost. Bois de Caures was then enveloped on the right and left and Col. Driant decided to withdraw his chasseurs to Beaumont. He was the last to leave the wood and was then killed. On the 23rd the village of Samogneux was overwhelmed by shells and set on fire but the garrison held on till night fell. On the extreme left the village of Brabant outflanked by the German advance became untenable and was evacuated. On the right Wavrille and Herbebois were lost and the front passed along the northern edges of Bois des Fossés and La Chaume.

In three days the Germans had captured the first of the French positions. Each side was reinforced on the 24th. A fresh regiment from the V. Res. Corps was sent to each of the German corps. The corps on the right which, having gained the greatest success, thereby became as it were a pivotal wing, also received a battalion of Jägers. On the French side the two divisions in line from the 21st were relieved, on the left by a division of the VII. Corps, on the right by two brigades from the XX. Corps. These troops, thrown at night into doubtful positions in the open country, were immediately destroyed. The 24th was the most critical day of the whole battle. On their right, where the Germans sought to move out from Samogneux, they were nailed down by the French artillery on the left bank. But they started a fresh attack immediately eastwards and captured all the line Beaumont, Bois des Fossés, Bois des Caurières. Further they penetrated towards Douaumont along the ravine of the Vauche.

The second French position was lost in one day. In the evening the situation was so grave that Gen. Langle de Cary, commanding the Centre group of Armies, ordered the II. Corps, then closely engaged in the Woëvre, to fall back on the Heights of the Meuse. This movement was carried out during the night. That same evening (24th) Gen. Joffre handed over the operations before Verdun to a fresh army, the II., commanded by Gen. Pétain, who after the Battle of Champagne had been resting at Noailles. The X. Army, on relief by the British Army, was placed in the general reserve.

New French Dispositions.—The initial task of the army under instructions of Feb. 25 at 9.00 A.M. was to concentrate the troops of the Verdun area on the west bank and to prevent the Germans from crossing the Meuse. But on the 24th at midnight Gen. Castelnau set out for Verdun armed with full powers from the commander-in-chief. He halted at Avize, headquarters of Gen. Langle de Cary, whence at 5.45 A.M. on the 25th he telephoned to Gen. Herr to order him to hold at all costs the line on the east bank facing north between the Meuse and Douaumont and, facing east, on the Heights of the Meuse. Gen. Pétain went on the morning of the 25th to Chantilly and thence to take charge of the battle, from the 25th at midnight.

During the 25th, on the French left, the Germans advanced 1,500 metres south of Samogneux up to the mill of Cotelettes. Further east they captured Bezonvaux. A party of Brandenburgers crept up to the fort of Douaumont, found it empty and took possession of it. Gen. de Bonneval, commanding the 37th Div. on the French left on the Talon and the Poivre Hills was afraid of being surrounded and ordered retreat on the Belleville Hills. This order was only partially carried out. The Zouaves held their position on the west of the Poivre. On the other hand while the 37th Div. retreated, the 39th Div. of the XX. Corps, going up into the line, passed it and covered the line Bras-Haudiomont.

On the 26th Gen. Pétain, at his headquarters at Souilly, reorganized the battle plan. He drew a sharp line—Bras-Douaumont—which he entrusted to the XX. Corps. He divided the area into four sections: (1) under Duchesne in the Woëvre, (2) under Balfourier from the Woëvre to Douaumont, (3) under Guillaumat astride the Meuse, and (4) under Bazelaire on the left bank. The artillery as it arrived was divided between these four commands. On Feb. 21 it consisted of 388 field guns and 244 heavy guns. In a few weeks there were 1,100 field guns, 225 guns of calibres from 80 to 105 mm. and 590 heavy guns. The French regained the mastery of the air. The 59th Div. was set to build two defensive positions chosen on the 27th and redoubled on March 2 by two intermediate lines. Three thousand territorials repaired and widened the Sacred Way.

Reinforcements arrived. The I. Corps was at Souilly on the 25th and the XIII. Corps at Revigny. The XXI. Corps followed it two days later. The XIV. Corps detrained on the 20th and the III. Corps on the 29th. Between the 26th and the 29th the Germans hurled violent attacks against Douaumont. On the east they reached the position of Hardaumont and attacked Bois de la Caillette. They stopped, exhausted, on the 29th.

The Second Phase.—The Germans failed to gain an immediate decision at Verdun. They soon realised that the British Army was about to attack them on the Somme. For four months they kept the battle of Verdun going with furious tenacity in order to disorganize the attack prepared by the Allies in Picardy. For the French Staff the problem was to hold on at Verdun without ceasing to prepare for the Somme. On March 6, as Gen. Pétain had expected and feared from the beginning, the Germans extended the action to the west bank. The attack was made by two corps, the VI. Res. and the X. Res., the latter taken from the General Reserve. On the 6th they captured the Hill de l'Oie and on the 10th Bois de Cumières. They were thus enabled to attack one of the pillars of the main line of defence, the Mort Homme. On the 14th they captured the lower crest of that double hill. The higher crest, Peak 295, could be held by neither side and was No Man's Land.

The second pillar of the French line, further to the west, and known as Hill 304, was attacked on March 20 by the 11th Bavarian Div. which took the Bois d'Avocourt but could not issue thence.

The Germans brought up fresh troops and the battle began again on March 28 on the west bank. It ended on April 8 by the French losing all that remained of their former front line. The new front passed thereafter by the redoubt at Avocourt, the first slopes of Hill 304, the southern reverse of the Mort Homme and the north of Cumières. On the right bank on March 31 the Germans captured the village of Vaux, which had held out till then, and on April 2 took the lake behind the village. Then on April 9 the Crown Prince attacked on both banks on a scale not known since the first attacks in February. The results were insignificant. On the morrow Gen. Pétain wrote in his orders of the day "the 9th April was a glorious day for our Armies . . . Courage. *Nous les aurons.*"

On April 20 the French counter-attacked on the east bank in order to clear the Mort Homme. But on May 3 the Germans renewed the offensive by an attack on Hill 304. On the 8th they captured Bois Camard, west of the Hill. On the 13th and 16th they attempted without success to advance from this position. They then organized a new attack on the 18th with a fresh corps, the XVIII. Res. Corps and two divisions of the XVIII. and added on the 22nd the 22nd. Res. Division. This violent battle ended on the 24th with the capture of Cumières. As the Germans had no reserves available the tired units could not be relieved and on the 26th they lost a portion of the trenches they had won.

There had been changes in the command. On April 2 the east bank sector had been placed under the orders of Gen. Nivelle, the west bank under Gen. Berthelot. At the end of April Pétain was called to command the Armies of the Centre and handed the II. Army over to Nivelle. The Germans, too, from March had divided the field of battle into two sections, Gen. von Mudra commanding on the right bank, Gen. von Gallwitz on the left bank. In April Mudra was replaced by Lochow. In July François relieved Gallwitz. The Allies' preparations on the Somme took definite shape. Before all things the Germans had to prevent the French from taking part in these operations. For this a new success in the Meuse was necessary.

The main French line of defence on the east bank was the Côte de Froide Terre—Fleury—Fort de Souville. On the right this position was covered by the fort of Vaux, on the left by the crest of Thiaumont. It was first necessary to capture Vaux and Thiaumont. On June 1 these two positions were attacked. Vaux was taken on the 9th. Thiaumont farm, taken by the Germans on the 1st, was recaptured by the French on the 2nd, who lost it again on the 9th. German attacks on the Thiaumont outworks behind

the farm failed completely. They succeeded in establishing themselves on the west and opposite side in the ravine of La-Dame. At the same time battle was resumed on the west bank. Between May 29 and 31 the Germans took Cumières but tried vainly to move out of Bois Camard against Hill 304.

Time pressed more and more. On June 4 Gen. Brusilov started a wide offensive in Volhynia. In these conditions the Germans delivered a large scale attack on the line Froide Terre–Souville on June 21. On the west the Bavarian Corps took the fortified post of Thiaumont but was checked in front of the fort at Froide Terre. In the centre the Alpine Corps captured Fleury. On the west the 103rd Div. took the first line of trenches in front of Souville but failed before the second line. So serious was the situation for the French that on June 23 Pétain warned Gen. Joffre and suggested moving to the west bank if the enemy reached the counterscarps. Joffre's answer on the 27th was a peremptory order to hold on to the east bank.

Meanwhile the preliminaries of the great Franco-British offensive on the Somme started on June 24 and the actual battle began on July 1. On July 11 the Germans made yet another attack on Verdun—from Vaux to Souville. It crumpled up on the slopes of Souville, the principal objective. On Aug. 3 the French retook Thiaumont and Fleury on Aug. 4. The Germans regained Thiaumont on the 8th. Throughout the whole month there was local fighting. The last German attack on Sept. 3 also failed. The battle of Verdun, properly called, had come to an end. From Feb. 21 to June 15 the Army at Verdun had seen 66 divisions on its front. Up to July 1 the Germans had used up 43½ divisions. It is true that they maintained them on the ground by depots situated a march behind the front and left them fighting till worn out. The French artillery fired 10,300,000 rounds with the field artillery, 1,200,000 rounds of medium and 600,000 rounds of large calibre.

II. THE FRENCH COUNTER-OFFENSIVE

On Sept. 13 M. Poincaré handed to Verdun the cross of the Legion of Honour and Allied decorations. The ceremony took place in the casemates of the citadel. From that moment began a new phase, that of the liberation of Verdun. To a large extent the glory of this feat belongs to Gen. Mangin. Called from the battlefield of Verdun on June 22 he was placed in command of Group D, which then stretched from the Meuse to Fleury and was progressively enlarged right up to the cliffs of the Meuse. On Sept. 17 in a report to Nivelle he set forth reasons for abandoning operations in detail and for seeking to free Verdun by a plan on broad lines.

The first scheme, approved by Nivelle on Sept. 21, dealt only with an advance up to 300 metres north of the farm of Thiaumont. The scheme of the 24th went further and included the fort of Douaumont as far as possible. A third scheme, that of Oct. 9, covered the capture of the fort of Douaumont and perhaps that of the fort of Vaux. A formidable artillery preparation with 650 guns started on Oct. 21. The assault was delivered on Oct. 24 at 11.40 A.M. by three divisions, the 38th on the left, 133rd in the centre, and 74th on the right. The first waves marched under a creeping barrage which progressed according to a set time-table, so that the infantry were as it seemed fastened to a wall of steel. By night Douaumont was taken with 6,000 prisoners. The division on the right had not reached the fort of Vaux which was evacuated by the Germans on Nov. 2, the day before the date fixed for attack by the 63rd Division.

In order to develop this success to the full Gen. Mangin was obliged to restore his ammunition reserves by continued economy. He intended to attack again on Dec. 5 over a front of 10 m. in order to retake at one blow the whole of the former second French line which had been lost on Feb. 24. Artillery preparation started on Nov. 29 with 750 guns. Bad weather intervened. The Germans had been warned and the value of a surprise was lost. In order to upset the plans of the French the Germans made a violent attack on Dec. 6 and captured Hill 304. Fine weather returned on the 9th and Nivelle recommenced the artillery preparation. On the 15th at 10 A.M. the attack was made. The German barrage started two minutes too late. The attack had started, four divisions being in line. By night they had retaken the whole of Poivre Hill. The line ran in front of Hill 378, stopped 20 metres south of the farm at Chambrettes, then turned south across Bois d'Hardaumont and la Vauche up to the outwork at Bezonvaux. The French captured 115 guns and 9,000 prisoners. This, known as the battle of Louvemont, was completed on the 18th by the recapture of Chambrettes. The spring passed in organising the area conquered and preparing for the final battle.

The Final Battle.—In the summer of 1917 Pétain formulated plans for a series of limited offensives for the purposes of raising the spirit of the army and decided on an operation on the northern front of Verdun on both banks having as objectives Mort Homme on the left and Samogneux and Beaumont on the right. The attack planned by Pétain was delivered on Aug. 20 after six days' heavy artillery preparation. The XIII. and XVI. Army Corps attacked on the left bank, the XV. and XXII. on the right bank, 16 divisions in all being engaged. Mort Homme was captured on the 20th, Hill 304 on the 24th. On the right bank Hill 344 was taken on the 20th, Samogneux on the 21st. More than 10,000 prisoners were taken. Beaumont alone remained in German hands. This was the final battle of Verdun.

VERE, SIR FRANCIS (1560–1609), English soldier, nephew of the 16th earl of Oxford, served under Leicester in the Low Countries from 1585, distinguishing himself at Sluys; he was given the chief command of the English troops there from 1589, and by a series of brilliant campaigns secured the independence of the country. He served in the Cadiz expedition of 1596, negotiated a treaty between England and Holland, and was appointed governor of Brill in 1598. On July 2, 1600, he and Prince Maurice completely defeated the Spaniards under the archduke Albert at Nieuwport, and defended Ostend successfully from July 1601 to March 1602. Vere retired from the Dutch service in 1604 and died in 1609. His *Commentaries of the Divers Pieces of Service wherein he had Command* (1657), was reprinted in Arber's *English Garner* (1883).

His younger brother, SIR HORACE VERE, BARON VERE OF TILBURY (1565–1635), served under his brother in Holland from 1590 to 1594, took part in the Cadiz expedition and held a command at Nieuwport and Ostend. On his brother's retirement he assumed command of the English troops until 1607. From 1609 to 1616 he was governor of Brill, and in 1610 was present at the siege of Jülich. He commanded the futile expedition to the Rhine and the Main, in aid of the elector palatine (1620); after the fall of Mannheim in 1622 he returned to England. After a brilliant attempt to relieve Breda (1624), which was foiled by Spinola, Vere was made Baron Vere of Tilbury. He retired from active service soon after serving at the sieges of Bois-le-duc and Maestricht, and died in 1635.

See Clements C. Markham, *The Fighting Veres* (1888).

VEREINIGTE GLANZSTOFF-FABRIKEN A.G., a German Company, was established at Elberfeld in the year 1899. The object of the Company is activity in the chemical and textile industry territory, and it deals chiefly with the manufacture of artificial silk. The Company used, at the beginning, for the manufacture of its artificial silk the copper-oxide-ammonia process. In later times, however, it has transferred the greater part of the work to the viscose process. The Company owns valuable patents concerning the manufacture of artificial silk, and its processes also find application in numerous similar undertakings which the Company has established in various countries, and in which it has obtained an influence by the purchase of blocks of shares. The Company's capital, which amounted at foundation to M.2,000,000. has now increased to M.76,500,000. of which

M.75,000,000 represent ordinary shares and M.1,500,000, 6% preference shares. The Company's artificial silk production, which has developed in the last 30 years from small beginnings, amounts in the German works belonging to the Company, employing 15,000 workers, to about 9,000,000 kilos yearly. (F. Bl.)

VEREINIGTE INDUSTRIE-UNTERNEHMUNGEN AKTIENGESELLSCHAFT (United Industrial Corporation), or Viag as it is commonly known, was formed in 1923 and is the holding company for various enterprises, controlled by the German Government. The business of this group includes the wholesale production of electric power, the manufacture of aluminium, nitrates, steel and miscellaneous products, the mining of lignite coal and banking.

The hydro-electric plants of the Viag system have an aggregate installed capacity of over 100,000 kw. The steam power plants of the system have an aggregate installed capacity of nearly 800,000 kw. During 1928 the combined output of the power plants controlled by Viag was in excess of 3,000,000,000 kw.

Through its subsidiaries engaged in the production of aluminium Viag is the dominant factor in the German aluminium industry. The aggregate production by these subsidiaries now exceeds 25,000 tons per annum. One of the Viag subsidiaries ranks among the leading companies in the German nitrate industry with an aggregate annual production of approximately 40,000 tons. Other subsidiaries of the Viag, domiciled in various parts of Germany, are engaged in the production of smelting and foundry products, motor-cycles, agricultural machinery, typewriters, textile machines, magnet armatures and precision-tools.

The banking subsidiary, Reichs-Kredit-Gesellschaft A.G., is an important factor in the economic life of Germany. It has capital, reserves and surplus of over £3,000,000.

In addition to the subsidiaries which it controls through the ownership of all or a majority of their capital stocks, Viag has large interests in other German enterprises. (G. Kr.)

VERESHCHAGIN, VASSILI VASSILIEVICH (1842–1904), Russian artist and traveller, was born at Tcherepovets, in the government of Novgorod, on Oct. 26, 1842. His father was a Russian landowner of noble birth, and from his mother he inherited Tatar blood. When he was eight years old he was sent to Tsarskoe Selo to enter the Alexander cadet corps, and three years later he entered the naval school at St. Petersburg, making his first voyage in 1858. He graduated first in the list from the naval school, but left the service immediately to begin the study of drawing in earnest. He studied at St. Petersburg and then at Paris under Gérôme. In the Salon of 1866 he exhibited a drawing of "Doukhobors chanting their Psalms," and in the next year he accompanied General Kauffmann's expedition to Turkestan, his military service at the siege of Samarkand procuring for him the cross of St. George. He was an indefatigable traveller—in Turkestan in 1869, the Himalayas, India and Tibet in 1873, and again in India in 1884. After a period of hard work in Paris and Munich he exhibited some of his Turkestan pictures in St. Petersburg in 1874, among them two which were suppressed for the time on the representations of Russian soldiers—"The Apotheosis of War," a pyramid of skulls dedicated "to all conquerors, past, present and to come," now in the Tretiakov Gallery, Moscow, and "Left Behind," the picture of a dying soldier deserted by his fellows. Vereshchagin was with the Russian army during the Turkish campaign of 1877; he was present at the crossing of the Shipka Pass and at the siege of Plevna, where his brother was killed; and he was dangerously wounded during the preparations for the crossing of the Danube near Rustchuk. At the conclusion of the war he acted as secretary to General Skobelev at San Stefano.

After the war Vereshchagin settled at Munich, where he produced his war pictures, which had a didactic aim, so rapidly that he was freely accused of employing assistants. He aroused much controversy by his series of three pictures of a Roman execution (the Crucifixion), of sepoys blown from the guns in India, and of the execution of Nihilists in St. Petersburg. A journey in Syria and Palestine in 1884 furnished him with an equally discussed set of subjects from the New Testament. The "1812" series on Napoleon's Russian campaign, on which he also wrote a book, seem to have been inspired by Tolstoi's *War and Peace,* and were painted in 1893 at Moscow, where the artist eventually settled. Vereshchagin was in the Far East during the Chino-Japanese War, with the American troops in the Philippines, and with the Russian troops in Manchuria. He perished in the sinking of the flagship, "Petropavlovsk," on the 13th of April, 1904.

VERGA, GIOVANNI (1840–1922), Italian novelist, was born at Catania, Sicily. In 1865 he published *Storia di una peccatrice* and *I Carbonari della montagna,* but his literary reputation was established by his *Eva* and *Storia di una capinera* (1869). Other novels followed, *Malavoglia* (1881) and *Maestro Don Gesualdo* (1889 Eng. trans. 1923). His finest work, however, is seen in his short stories and sketches of Sicilian peasantry, *Medda* (1874) and *Vita dei campi* (1880); and his *Cavalleria Rusticana* (Eng. trans. of this and other stories 1928) acquired new popularity from its dramatization and from Mascagni's opera on this subject. Verga and Fogazzaro between them may be said to have faithfully chronicled the inner and popular life of southern and northern Italy. D. H. Lawrence translated many of Verga's works into English. Verga died in Rome on Jan. 27, 1922.

VERGENNES, CHARLES GRAVIER, Comte de (1717–1787), French statesman, was born at Dijon on Dec. 20, 1717. He entered the diplomatic service under his uncle M. de Chavigny, at Lisbon. He became ambassador at Constantinople and then in Sweden, where he assisted Gustavus III. in the revolution of 1772.

With the accession of Louis XVI. Vergennes became foreign minister. His general policy was one of friendly relations with Austria, combined with the limitation of Joseph II.'s ambitious designs; the protection of Turkey; and opposition at all points to England. His hatred of England led to his support of the American States in the War of Independence. Vergennes sought to secure the armed neutrality of the Northern Powers eventually carried out by Catherine II.; he ceded to the demands of Beaumarchais that France should secretly provide the Americans with arms and volunteers. In 1777 he informed the American commissioners that France was willing to form an offensive and defensive alliance with the new Republic. In 1781 he became chief of the council of finance. Vergennes died on Feb. 13, 1787.

VERGNIAUD, PIERRE VICTURNIEN (1753–1793), French orator and revolutionist, was born on May 31, 1753 at Limoges. The son of a merchant of that town, he attracted the notice of Turgot, who was then intendant of Limousin. Turgot secured his admission to the college of Plessis in Paris, where he received a solid classical education. On leaving college he became secretary to Duputy, president of the parlement of Bordeaux. Vergniaud was thereafter called to the bar (1782). In 1789 Vergniaud was elected a member of the general council of the department of the Gironde. He was chosen a representative of the Gironde to the National Legislative Assembly in August 1791.

The extremists used the passions which his oratory awakened for objects he did not foresee. This happened even with his first Assembly speech, on the *émigrés.* His proposal was mainly that a treble annual contribution should be levied on their property; but the Assembly confiscated their goods and decreed their deaths. Step by step he was led on to palliate violence and crime, to the excesses of which his eyes were only opened by the massacres of September, and which ultimately overwhelmed the party of Girondists which he led. It has always been held against him that on March 19, 1792, when the perpetrators of the massacre of Avignon had been introduced to the Assembly by Collot d'Herbois, Vergniaud spoke indulgently of their deeds and lent

the authority of his voice to their amnesty. In language sometimes turgid, but nearly always of pure and powerful eloquence, he worked at the theme of the *émigrés*, as it developed into that of the counter-revolution; and the project of an address to the French people which he presented to the Assembly on Dec. 27, 1791, shook the heart of France; and, especially by his call to arms on Jan. 18, he shaped the policy which culminated in the declaration of war against the king of Bohemia and Hungary on April 20. This policy in foreign affairs, which he pursued through the winter and spring of 1791–92, he combined with another—that of fanning the suspicions of the people against the monarchy, which he identified with the counter-revolution, and of forcing on a change of ministry. On March 10, Vergniaud delivered a powerful oration in which he denounced the intrigues of the court and uttered his famous apostrophe to the Tuileries: "In ancient times fear and terror have often issued from that famous palace; let them re-enter it to-day in the name of the law!" The speech overthrew De Lessart, whose accusation was decreed; and Roland, the nominee of the Girondists, entered the ministry. The Mountain used Vergniaud, whose lofty and serene ideas they applauded and travestied in action. Then came the riot of June 20, and the invasion of the Tuileries. He rushed among the crowd, but was powerless to quell the tumult. But his speeches breathe the very spirit of the storm, and they were perhaps the greatest single factor in the development of the events of the time. On Aug. 10, the Tuileries was stormed, and the royal family took refuge in the Assembly. Vergniaud presided. To the request of the king for protection he replied in dignified and respectful language.

On Dec. 31, 1792, Vergniaud delivered one of his greatest orations. He pictured the consequences of that temper of vengeance which animated the Parisian mob and was fatally controlling the policy of the Convention, and the prostration which would ensue to France after even a successful struggle with a European coalition, which would spring up after the murder of the king. On Jan. 16, 1793, the vote began to be taken in the Convention upon the punishment of the king. Vergniaud voted early, and voted for death. The action of the great Girondist was and will always remain inscrutable, but it was followed by a similar verdict from nearly the whole party which he led. On the 17th Vergniaud presided at the Convention, and it fell to him to announce the fatal result of the voting. Then for many weeks he was silent.

When the institution of a revolutionary tribunal was proposed, Vergniaud vehemently opposed the project, denouncing the tribunal as a more awful inquisition than that of Venice, and avowing that his party would all die rather than consent to it. On April 10 Robespierre himself laid his accusation before the Convention. Vergniaud made a brilliant extemporaneous reply, and this attack failed. The Girondists continued their resistance to the dominant faction, till on June 2, 1793 things came to a head. The Convention was surrounded with an armed mob, who clamoured for the "twenty-two." The decree of accusation was voted, and the Girondists were proscribed.

Vergniaud was offered a safe retreat. He accepted it only for a day, and then returned to his own dwelling. He was kept under surveillance there for nearly a month, and in the early days of July was imprisoned in La Force. The Girondists appeared before the Revolutionary tribunal on Oct. 27. Early on the morning of Oct. 31, 1793 they went to the scaffold. Vergniaud was executed last. He died unconfessed, a philosopher and a patriot.

See Gay de Vernon, *Vergniaud* (Limoges, 1858); and L. de Verdière, *Biographie de Vergniaud* (Paris, 1866); E. Lentilhac, *Vergniaud, Le drame des Girondins* (1920). (SH.; X.)

VERHAEREN, ÉMILE (1855–1916), Belgian poet, born at St. Amand, near Antwerp, on May 21, 1855, studied at Ghent and at the university of Louvain, and was admitted to the bar at Brussels in 1851. But he soon devoted his whole energies to literature, and especially to the organs of "young Belgium," *La Jeune Belgique* and *L'Art moderne*, making himself especially the champion of the impressionist painters. Verhaeren learnt his art of poetry from the great Flemish artists, and in his early works, *Les Flamandes* (1883), and *Les Moines* (1886) displays similar qualities of strength, sometimes degenerating into violence and even into coarseness. A period of despair and disillusionment is reflected in his *Les Soirs* (1887), *Les Débâcles* (1888), *Les Flambeaux noirs* (1889) and *Les Apparus dans mes chemins* (1891). Wandering over Europe from 1887 to 1892, Verhaeren found a new interest in social problems, and his *Campagnes hallucinées* (1893) and *Les Villes tentaculaires* (1895) both deal with the growth of industrialism and its evils.

A genuine optimism based on an appreciation of the greatness of human life and progress appears in *Les Visages de la vie* (1899), *Les Forces tumultueuses* (1902) and *La Multiple Splendeur* (1906), and a delight in natural beauty runs through his chief work *Toute la Flandre*, a collection of lyrics in 5 vols. (1904–11), the first volume dealing with the memories of his boyhood, *Les tendresses premières*, being the best. The others describe: the Flemish coast, *La Guirlande des dunes;* various episodes of Flemish history, *Les héros;* life in the small towns, *Les villes à Pignons;* and the Flemish countryside, *Les plaines* and *Les blés mouvants*. In 1911 Verhaeren published *Les heures du soir*, a series of intimate poems dedicated to his wife, completing two previous series *Les heures de l'après-midi* (1905) and *Les heures claires* (1896). During the World War, the poet wrote *Les ailes rouges de la guerre* (1916) which contains an ode to Rupert Brooke, and two short volumes of prose, *La Belgique sanglante* (1915, Eng. trs. 1915), and *Parmi les cendres* (1916). He died on Nov. 27, 1916, a victim of a railway accident in Rouen station.

Among Verhaeren's subsidiary activities may be mentioned his critical studies, some of which have been published as *Impressions* (Paris, 1927), and his plays, *Les Aubes* (1898), *Le Cloître* (1900, Eng. trs. 1915), *Philippe II.* (1901) and *Hélène de Sparte* (1912), translated in 1916.

A selection of his poems has been translated by M. Strettell (2nd ed. 1915) and his *Love Poems* by F. S. Flint (1916). *See* also L. Bazalgette, *É. Verhaeren* (1907); S. Zweig, *É. Verhaeren* (Eng. trs. 1914); A. Mockel, *Un Poète de l'énergie, É. Verhaeren* (1917); J. de Smet, *É. Verhaeren*, 2 vols. (1909–20); L. Charles-Baudouin, *Lé Symbole chez Verhaeren* (4th ed. 1924), and P. Mansell Jones, *É. Verhaeren* (Cardiff, 1926, bibliography).

VERKHNE-UDINSK, a town of Asiatic Russia in the Buriat-Mongol A.S.S.R., of which it is the administrative centre. It is on the Uda river, at its confluence with the Selenga, and has steamer communication with Lake Baikal, and southwards with Mongolia. It is also on the Siberian railway, and has grown markedly since the railway was constructed in 1905. The climate is extreme, average July temperature 66·2°, Jan. −17·3° F. The water supply to the railway in winter is a difficulty, since the ground is frozen and water pipes cannot be buried below frost level. Pop. (1926) 27,571. The town was on the 18th century military Siberian road and was formerly a great centre for the tea trade from Mongolia via Kiakhta. (*See* TROITSKOSAVSK.)

VERLAINE, PAUL (1844–1896), French lyric poet, was born at Metz on March 30, 1844. He was the son of one of Napoleon's soldiers, who had become a captain of engineers. Paul Verlaine was educated in Paris, and became clerk in an insurance company. He was a member of the Parnassian circle, with Catulle Mendès, Sully Prudhomme, François Coppée and the rest. His first volume of poems, the *Poèmes saturniens* (1866), was written under Parnassian influences, from which the *Fêtes galantes* (1869), as of a Watteau of poetry, began a delicate escape; and in *La Bonne Chanson* (1870) the defection was still more marked. He married in 1870 Mlle. Mautet. During the Commune he was involved with the authorities for having sheltered his friends, and was obliged to leave France. In 1871 the strange young poet Jean Arthur Rimbaud came somewhat troublingly into his life, into which drink had already brought a lasting disturbance.

With Rimbaud Verlaine wandered over France, Belgium, England, until a pistol-shot, fortunately ill-aimed, against his companion brought upon him two years of imprisonment at Mons. Solitude, confinement and thought converted a pagan into a Catholic, without, however, rooting out what was most human in the pagan; and after many years' silence he published *Sagesse* (1881), a collection of religious poems, which, for humble and passionate conviction, as well as originality of poetic beauty, must be ranked with the finest religious poems ever written. *Romances sans*

paroles, composed during the intervals of wandering, appeared in 1874, and shows us Verlaine at his most perfect moment of artistic self-possession, before he has quite found what is deepest in himself. He returned to France in 1875. His wife had obtained a divorce from him, and Verlaine made another short stay in England, acting as a teacher of French. After about two years' absence Verlaine was again in France. He acted as teacher in more than one school and even tried farming. The death of his mother, to whom he was tenderly attached, dissolved the ties that bound him to "respectable" society. During the rest of his life he lived in poverty, often in hospital, but always with the heedless and unconquerable cheerfulness of a child. After a long obscurity, famous only in the Latin Quarter, among the cafés where he spent so much of his days and nights, he enjoyed at last a European celebrity. In 1894 he paid another visit to England, this time as a distinguished poet. He died in Paris on Jan. 8, 1896.

His 18 volumes of verse (among which may be further mentioned *Jadis et naguère,* 1884; *Amour,* 1888; *Parallèlement,* 1889; *Bonheur,* 1891) vary greatly in quality. (A. Sy.)

His *Oeuvres complètes* were published in 1899 and in later editions, and his *Oeuvres posthumes* in 1903. His *Poètes maudits* (1888) and *Confessions* (1895) throw light on his own life. A bibliography of Verlaine, with an account of the existing portraits of him, is included in the *Poètes d'aujourd'hui* (11th ed., 1905) of A. van Bever and P. Léautaud. *See* monographs by C. Morice (1888), M. Dullaert (Ghent, 1896), B. E. Delahaye (1919), and H. Nicolson (1921); E. Lepelletier, *Paul Verlaine, sa vie, son oeuvre* (1907, Eng. trans. 1909); F. A. Cazals and G. Le Rouge, *Les Derniers Jours de P. Verlaine* (1923); L. Eckhoff, *P. Verlaine og Symbolismen* (Oslo, 1923).

VERMEER, JAN VAN DELFT or Jan van der Meer (1632–1675), Dutch artist, was born in Delft on Oct. 31, 1632, and was a pupil of Carel Fabritius, whose junior he was by only eight years. In 1653 he married Catherine Bolens, and entered the gild of St. Luke of Delft, becoming one of the heads of the gild in 1662 and again in 1670. He died at Delft on Dec. 15, 1675, leaving a widow and eight children. At his death he left 26 pictures undisposed of, and his widow had to apply to the court of insolvency to be placed under a curator, who was Leeuwenhoek, the naturalist. For more than two centuries Vermeer was almost completely forgotten, and his pictures were sold under the names of the more popular De Hooch, Metsu, Ter Borch, and even of Rembrandt. Attention was recalled to this most original painter by Thoré (pseudonym, W. Bürger), an exiled Frenchman, who described his works in *Musées de la Hollande* (1858–60).

Vermeer's pictures are rarely dated, but one of the most important, in the Dresden gallery, bears the date 1656, and thus gives us a key to his styles. With the exception of the "Christ with Martha and Mary" in the National Gallery of Scotland, Edinburgh, it is perhaps the only one, hitherto recognized, that has figures of life size. The Dresden picture of a "Woman and Soldier," with two other figures, is painted with remarkable power and boldness; for strength and colour it more than holds its own beside the neighbouring Rembrandts. To this early period of his career belong, from internal evidence, the "Reading Girl" of the same gallery, the luminous and masterly "View of Delft" in the museum of The Hague, the "Milk-Woman" and the small street view, both identified with the Six collection at Amsterdam, and now in the Rijksmuseum; the magnificent "The Letter" also at Amsterdam, "Diana and the Nymphs" at The Hague gallery and others. In all these we find the same brilliant style and vigorous work, a solid impasto, and a crisp, sparkling touch. His first manner seems to have been influenced by the pleiad of painters circling round Rembrandt, a school which lost favour in Holland in the last quarter of the century. During the final ten or 12 years of his life Vermeer adopted a second manner. We now find his painting smooth and thin, and his colours paler and softer. Instead of masculine vigour we have refined delicacy and subtlety, but in both styles beauty of tone and perfect harmony are conspicuous. Through all his work may be traced his love of lemon-yellow and of blue of all shades. Of his second style typical examples are to be seen in "The Coquette" of the Brunswick gallery, in the "Woman Reading" in the Van der Hoop collection now at the Rijksmuseum at Amsterdam, in the "Lady at a Casement" in the Metropolitan Museum of Art at New York, and in the "Music Master and Pupil" belonging to the King (exhibited at the Royal Academy, 1876).

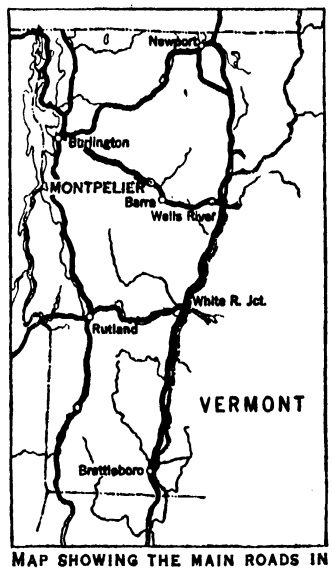
Vermeer's authentic pictures in public and private collections amount to 37. There is but one in the Louvre, the "Lace Maker"; Berlin has three, all acquired in the Suermondt collection, and the Czernin gallery of Vienna possesses a fine picture, believed to represent the artist in his studio. In the Arenberg gallery at Meppen and in The Hague Museum there are two remarkable heads of girls, half life size.

See Thoré, a monograph in *Gazette des Beaux Arts* (1866); Harvard, *Van der Meer* (1888); Hofstede de Groot, *Jan Vermeer von Delft* (Leipzig, 1909); G. Vansype, *Jan Vermeer de Delft* (1921).

VERMIGLI, PIETRO MARTIRE, generally known as Peter Martyr (1500–1562), born at Florence on May 8, 1500, was son of Stefano Vermigli, a follower of Savonarola, by his first wife, Maria Fumantina. Educated in the Augustinian cloister at Fiesole, he was transferred in 1519 to the convent of St. John of Verdara near Padua, where he graduated D.D. about 1527 and made the acquaintance of the future Cardinal Pole. In 1530 he was elected abbot of the Augustinian monastery at Spoleto, and in 1533 prior of the convent of St. Peter *ad Aram* at Naples. About this time he read Bucer's commentaries on the Gospels and the Psalms and also Zwingli's *De vera et falsa religione;* and his Biblical studies began to affect his views. He was accused of erroneous doctrine, and the Spanish viceroy of Naples prohibited his preaching. The prohibition was removed on appeal to Rome, but in 1541 Vermigli was transferred to Lucca, where he again fell under suspicion. Summoned to appear before a chapter of his order at Genoa, he fled in 1542 to Pisa and thence to another Italian reformer, Bernardino Ochino, at Florence. Ochino escaped to Geneva, and Vermigli to Zürich, thence to Basel, and finally to Strasbourg, where, with Bucer's support, he was appointed professor of theology and married his first wife, Catherine Dammartin of Metz.

Vermigli and Ochino were both invited to England by Cranmer in 1547, and given a pension of forty marks by the government. In 1548 Vermigli was appointed regius professor of divinity at Oxford. In 1549 he took part in a great disputation on the Eucharist. He had abandoned Luther's doctrine of consubstantiation and adopted the doctrine of a Real Presence conditioned by the faith of the recipient. This was similar to the view now held by Cranmer and Ridley, but it is difficult to prove that Vermigli had any great influence in the modifications of the Book of Common Prayer made in 1552. He was consulted on the question, but his recommendations seem hardly distinguishable from those of Bucer, the effect of which is itself disputable. He was also appointed one of the commissioners for the reform of the canon law. On Mary's accession Vermigli returned to Strasbourg, where he was reappointed professor of theology, but his increased alienation from Lutheranism drove him to Switzerland. He was professor of Hebrew at Zürich, where he died on Nov. 12, 1562.

Josias Simler's *Oratio,* published in 1563 and translated into English in 1583, is the basis of subsequent accounts of Vermigli. The best lives are by F. C. Schlosser (1809) and C. Schmidt (1858). *See* also Parker Soc. Publ. (General Index), especially the Zürich *Letters,* Strype's *Works;* Foxe's *Acts and Monuments;* Burnet's *Hist.,* ed. Pocock (1865); Dixon's *History* (6 vols., 1878–1902); and *Dict. of Nat. Biogr.* lviii. 253–256.



VERMILION, a city of South Dakota, U.S.A., and the seat of the State university. Pop. (1925 State census) 3,410. A trading post was established here soon after the first steamboat came up the Missouri river in 1832, and numerous settlers came before the public land was thrown open in 1859. The city was incorporated in 1877. A monument marks the site of the first school building erected in the State. The university was established (and located in Vermilion) by the first Territorial Legislature of Dakota in 1862, but was not opened until 1882. The enrolment in 1926–27 was 1,375.

VERMILION, a scarlet pigment, which occurs naturally as the crystalline mineral cinnabar. It is the red form of mercuric sulphide, HgS, and is prepared artificially to-day by subliming an intimate mixture of mercury and sulphur, or by grinding

such a mixture for some hours, digesting it in a solution of caustic potash, and warming at or below 45° C to convert the black mercuric sulphide to the scarlet-red modification; Chinese vermilion is said to be made by the latter process. Vermilion blackens in oil on exposure to sunlight and its cost has caused it to be largely superseded by the cheaper and more permanent aniline lakes. *See* PAINTS, CHEMISTRY OF.

VERMONT, the Green Mountain State, so named from the evergreen forests of its mountains, is a North Atlantic State of the United States of America, and the most north-westerly of the so-called New England group. It is situated between 42° 44′ and 45° 0′ 43″ N. lat. and 71° 28′ and 73° 26′ W. longitude. It is bounded north by the Canadian province of Quebec, east by New Hampshire, from which it is separated by the Connecticut river, south by Massachusetts, and west by New York, from which it is separated for about two-thirds the distance by Lake Champlain. In length, north and south, the State measures 157·6 m.; its approximate width at the northern border is 90 m., at the southern border 40 miles. Its total area is 9,564 sq.m., and of this 440 sq.m. is water surface.

Physical Features.—The mean elevation of the State above the sea is approximately 1,000 ft., extremes varying from 95 ft., the surface of Lake Champlain, to 4,393 ft. at the summit of Mt. Mansfield, 25 m. E. of that lake. The general surface is much broken by mountain ranges. The most prominent feature is the Green mountains, which extend nearly north and south through the State a little west of the middle. Farther north, the Green mountains are cut deep by the Winooski and Lamoille rivers which rise to the east and break through it to flow into Lake Champlain. The Missisquoi river also rises east of the range but flows just north of the Canadian boundary, and then back into Vermont and west to Lake Champlain. The crest line of the Green mountains is generally more than 2,000 ft. high, with the following summits: Mt. Mansfield, 4,393 ft.; Killington Peak, 4,241 ft.; Mt. Ellen, 4,135 ft.; Camel's Hump, 4,083 ft.; and Mt. Abraham, 4,052 ft. Distributed along the eastern border of the state are conical shaped mountain masses. Mt. Ascutney rises abruptly from the floor of the Connecticut valley to a height of 3,320 feet. Other prominent peaks are Jay Peak, Burke and Belvidere mountains. In the southern half of Vermont and near the western border are the Taconic mountains, a range nearly parallel with the Green mountains and extending northward toward the centre of the State. To the northward of the Taconic ranges extends a series of broken uplifts known as the Red Sandrock mountains. These are near Lake Champlain, and, standing in a low country, are unusually conspicuous. The least broken section of Vermont is on the somewhat gentle slope of the Green mountains in the north-west and on Grand isle, North Hero island and Isle La Motte in Lake Champlain. The forms of Vermont's mountains, even to the highest summits, were to a great extent rounded by glaciation, but as the rocks vary much in texture and are often steeply inclined, stream erosion has cut valleys deep and narrow, often mere gorges. The Green Mountain club, since 1910, has been building a well marked "Long Trail" reaching from Massachusetts to Canada which follows the Green mountain range.

MAP SHOWING THE MAIN ROADS IN VERMONT

Lake Champlain lies in a beautiful valley between the Green and Adirondack mountains, and a little more than half its area is in Vermont. The lake is about 118 m. long, and in its northern portion are numerous islands which are attractive resorts during the summer season. These islands are large enough to constitute an entire county in themselves, and are connected with each other and with the mainland by bridges. On the north border of the State is Lake Memphremagog with islands, a rugged prominence known as Owl's Head on its west border, Jay Peak farther back, and a beautiful farming country to the eastward. The lake is 30 m. long and from 1 to 4 m. wide but two-thirds of its area lies in Canada. The Vermont tributaries to Memphremagog are the Barton and the Black rivers from the south and the Clyde river from the east. There are many other lakes and ponds in the State, the section in which they are most numerous being the north-eastern part. Here Willoughby lake is one of the largest and one of the most beautiful, lying as it does in a narrow valley between Mt. Pisgah and Mt. Hor. Lakes Morey and Fairlee, in the Connecticut river valley, are popular resorts. Lake Dunmore in Salisbury and Leicester, Lake Bomoseen in Castleton, and Hubbardton, Lake St. Catherine in Wells and Poultney and Lake Hortonia in Sudbury, west of the Green mountains, are noted for the charm of their scenery.

Most important of the Vermont tributaries of the Connecticut river are the Nulhegan, Passumpsic, Wells, Waits, Ompompanoosuc, White, Ottauquechee, Black, Williams, Saxtons, West and Deerfield, the last-named emptying into the Connecticut in Massachusetts. The south-western part of the State is drained to the Hudson river by the Battenkill and Hoosac rivers, while Otter creek flows north and slightly west to Lake Champlain. The streams are usually swift-flowing and in comparatively narrow and beautiful valleys. On the headwaters of the Deerfield are great power developments. In the valleys are soils of great fertility, while the low rolling hills and uplands make excellent pasture. On the lower slopes of the mountains are white pine and hemlock; on the higher slopes spruce and fir are common. Among deciduous trees the State is especially noted for its sugar maples. Birch and beech are to be expected on the hills and in the lower areas oak, elm, hickory, ash, poplar, basswood, willow and butternut are to be found. Among indigenous fruit-bearing trees, shrubs, vines and plants are the plum, cherry, grape, blackberry, raspberry, cranberry and strawberry. There were in 1928, 18 State forests with an aggregate area of 33,725 acres. These were patrolled regularly by the State forest service which since its establishment in 1909 had planted about 13,000,000 trees.

The temperature, the amount of moisture and the winds are favourable to the health of the people and to the productiveness of the soil. The mean annual temperature varies from 40° to 47° F, the eastern part of the State being generally colder than the western part, and the mountainous part of the centre coldest of all. The average annual precipitation over a long period of years is approximately 37·5 inches. Snow often appears in November in the higher altitudes but does not come to stay before December. It remains until the latter part of March. The average fall throughout the State is about 90 in. annually, but there is less snow near Lake Champlain and in the south-western part than in central and eastern Vermont. Also spring comes earliest in these sections and in the lower portion of the Connecticut valley.

Population.—The population of Vermont in 1900 was 343,641; in 1910, 355,956; in 1920, 352,428. Its rank among the 48 States in 1920 was 44th. It was one of only three in the United States, and the only one of the New England group, in which the population decreased between 1910 and 1920. The density in 1920 was 38·6 per square mile.

Of the 1920 population, 351,817, or 99·8% were whites, a percentage not exceeded in any other State. Of the whites, 44,526 or 12·7%, were foreign-born. Of the native-born 228,325 were of native parentage, 36,866 of mixed parentage, and 44,526 of foreign parentage. Chief among the foreign-born were the 24,868 Canadians, 14,181 of them of French blood.

In 1920 more than two-thirds the population (68·8%) were rural inhabitants. The percentage of urban population increased, however, from 22·1% in 1900 to 27·8% in 1910 and 31·2% in 1920. The largest cities with their estimated population in 1925 were: Burlington, 24,089; Rutland, 15,752; Barre, 10,008. The population of Montpelier, the capital, was 7,125 in 1920.

Government.—The State is governed under a Constitution

adopted in 1777, but since amended in important respects. An amendment in 1870 provided that every ten years the senate, by a two-thirds vote, is authorized to propose amendments, which proposals, if concurred in by the majority of the members of the house of representatives, are published in the principal newspapers of the State. If they are again approved by a majority of each house in the next succeeding general assembly, they are submitted to a direct popular vote, a majority of the votes cast being decisive. The amendment sessions are those in years ending with the figure one, such as 1921, 1931, etc. In the 1921 session 21 proposals were submitted to the senate of which four ultimately became part of the Constitution. The right of suffrage is possessed by all citizens above 21 years of age who have lived in the State for one year, and who are "of a quiet and peaceable behaviour" and will take the freeman's oath.

The legislative department consists of a senate of 30 members, apportioned among the counties according to population, but with the proviso that each county must have at least one senator, and a house of representatives of 248 members, one from each township. The members of both houses are elected biennially. Sessions are also held biennially beginning on the first Wednesday after the first Monday of January in odd-numbered years. The governor has power to call special sessions when he deems it necessary.

The most important executive officers of the State are the governor, lieutenant-governor, secretary of State, treasurer, auditor of accounts and attorney-general, all elected by the people for terms of two years. In 1923 there were created seven administrative departments: agriculture, education, finance, highways, public health, public service and public welfare, each presided over by a commissioner or secretary. In 1927 the department of motor vehicles was created with a commissioner in charge.

The supreme court consists of one chief justice and four associate justices. Annually five general terms are held at Montpelier and special sessions at St. Johnsbury, Rutland and Brattleboro. The supreme court justices are elected biennially by the senate and house of representatives in joint session. At the same session, in like manner, six superior judges are elected for two year terms to preside over the county courts to which they are assigned. A superior judge has two assistant judges in each county who are elected by the freemen of that county, and these three compose the county court, two sessions of which are held annually in each county.

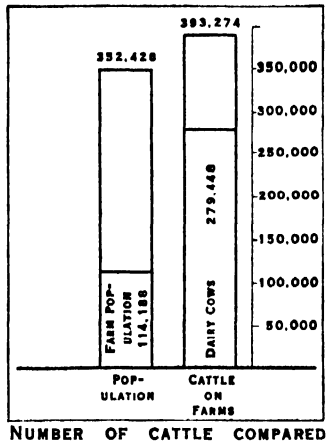
Finance.—The wealth of Vermont, as estimated by the bureau of the census, increased from $505,000,000 in 1912 to $842,000,000 in 1922. The per caput increase was from $1,407 to $2,389, the latter figure being still below the average per caput wealth of $2,918 for the entire United States in 1922.

The gross receipts of the State treasury for the fiscal year ending June 30, 1928, amounted to $14,723,920.50. Disbursements for the same period were $11,199,998.90. The balance in the treasury at the end of the fiscal year was $5,228,438.70. Of the receipts $10,447,905.89 was provided from miscellaneous sources and $4,276,014.61 from taxes. The chief items of miscellaneous revenue were State flood bonds, $5,000,000; motor vehicle fees, $2,034,333.50; proceeds from temporary loans, $1,050,000; and aid for Federal highway projects, $944,060.84. Of the tax receipts, $2,290,929.56 was from corporation taxes, $362,511.24 from inheritance taxes, $223,069.76 from a direct State tax, $142,496.63 from a State tax for highways, $971,983.40 from a gasolene sales tax and $285,024.02 from a school tax.

The State debt on June 30, 1928, was $6,621,531.90. Of the total debt $5,000,000 represented flood bonds issued to repair the flood losses of Nov. 1927, and $970,000, war bonds. The debt of the local governments within the State totalled $9,882,000 in 1922.

There were on June 30, 1928, 105 banking institutions in the State, 46 of them national banks (statistics of national banks as of Oct. 10, 1927) with total resources and liabilities of $275,548,000. Their capital, surplus and undivided profits totalled $29,673,000 and deposits were $224,104,000. Of the deposits $166,393,000 were in savings accounts. Vermont ranked third among the States in per caput deposits in savings banks.

Education.—The public school system is directed by the board of education, and administered by the commissioner of education, assisted by superintendents in each district. Attendance is compulsory for all children between 8 and 16 years of age. In 1925 there were 75,772 children between 6 and 18 years of age and during the 1927–28 school term 64,529 were enrolled in the public schools. In addition there were approximately 7,500 pupils in private and parochial schools. The number of public schools totalled 2,205, of which 95 were high schools. There were 2,291 elementary school teachers and 557 high school teachers. High school enrolment was 11,018. There were also 18 private high schools and academies with 2,407 pupils. All expenditures for the public school system totalled $5,174,945.08 for the year 1927–28, of which $953,332.77 was used for the maintenance of the high schools. Public school property was valued at $10,538,684. The average expenditure per school child was $80.20 in 1927–28 as compared with an average of $65.51 for the entire United States.



There are two-year normal school courses given at the University of Vermont, and in normal schools at Castleton, Johnson and Lyndon. One-year teachers' training courses were given in six high schools in 1927–28. In 1922 high school graduation was made a requirement for entering either the one-year or two-year normal courses.

The University of Vermont, chartered by the State in 1791, occupies a 75 ac. campus on a hill overlooking the city of Burlington and the Champlain valley. It is composed of an undergraduate college, college of engineering, college of medicine and college of agriculture. Its library, containing about 125,000 volumes and 45,000 pamphlets in 1928, is the largest in the State. Middlebury college, at Middlebury, chartered in 1800, is a liberal arts college of high standing, doing excellent work. Norwich university at Northfield is the State military college at which engineering courses and military training are emphasized. St. Michael's Roman Catholic college is at Burlington.

Charities and Correction.—The department of public welfare is charged with the scientific treatment and care of the State's unfortunates. It also has charge of the administration of the State charitable and penal institutions, which are as follows: School for Feeble-minded Children, at Brandon; Industrial School for Delinquent Boys and Girls, at Vergennes; State Prison and House of Correction for Men at Windsor; State Prison and House of Correction for Women at Rutland; Hospital for the Insane at Waterbury; the Vermont Sanatorium for Incipient Tuberculosis at Pittsford. The State makes other provision for insane by paying for them at the Brattleboro Retreat, a private hospital not operated for profit. The Washington County hospital at Barre for the treatment of tuberculosis and the Caverly preventorium at Pittsford for undernourished or tuberculous children are private institutions at which patients are cared for at State expense. The department maintains Kinstead Receiving home for dependent and neglected children at Montpelier.

Agriculture and Live Stock.—Of the total land area of the State—approximately 5,839,000 ac.—67·2% or 3,926,000 ac. was in farm land in 1925, and of this 1,692,000 ac. represented improved land. This was divided among 27,786 farms, as compared with 29,075 farms in 1920 and 32,709 farms in 1910. The average size per farm was 141·3 acres. Of the farm land 1,150,000 ac. was crop land, 2,176,000 ac. was in pasture, of which 1,031,000 ac. was wooded, and 518,000 ac. was in woodland not used for pasture. Farm population in 1925 was 114,188, or 32·4% of the total population. In 1920 it had been 125,263, in 1910, 142,372. The value of all farm property was estimated at $145,400,000 in 1910, $222,737,000 in 1920 and $180,912,000 in 1925. Between 1920 and 1925 land decreased $19,000,000, buildings decreased $3,000,000, implements and machinery decreased $3,000,000 and live stock decreased $17,000,000 in value. The average value per farm was: in 1920, $7,661, in 1925, $6,511 and the average value of farm land per acre was respectively $19.58 and $16.27. In 1925 9·3% of the farms were operated by tenants. The number of mortgaged farms was 10,850 and the mortgaged debt approximated $25,000,000.

Between 1925 and Jan. 1, 1928, the value of cattle, horses, swine and sheep rapidly increased, totalling $13,829,000, most of which came in the year 1927. With an increase also in the value of dairy and other live stock products, live stock raising returned practically to the level of prosperity it enjoyed before the depression following the World War. There were in 1928, 404,000 cattle of all kinds, valued at $32,158,400, as compared with 403,000 valued at $18,538,000 in 1925. Of the number in 1928, 284,000 were milch cows valued at $28,116,000. The great acreage of excellent grass land to be found on the upland pastures of Vermont, together with the abundant hay crop, makes dairying the chief industry of Vermont farmers. The ratio of dairy cows per caput was the highest of any State. Butter made in 1926 totalled 8,305,000 lb. and cheese amounted to 1,114,000 pounds.

NUMBER OF CATTLE COMPARED WITH THE TOTAL POPULATION AND FARM POPULATION (1925)

The value of all crops totalled $42,200,000 in 1925 and $42,500,000 in 1926. Chief of these was hay, which alone amounted in value in 1926 to $21,184,000, or slightly more than all other crops together. Another industry, carried on largely by the farmers, is the maple sugar industry for which Vermont particularly among the States is famous. In 1926 there were 5,544,000 trees tapped, far more than in any other State. Of the sap there were made 1,602,000 lb. of maple sugar, and 980,000 gal. of maple syrup. The value amounts annually to about $1,500,000.

Mines and Quarries.—The mineral wealth except for talc mines comes entirely from quarries. The leading products in 1926, in order of their value, were stone, slate, talc and lime. The total value was $14,176,617 in 1926.

In 1926, 117,200 tons of granite valued at $3,908,917 were quarried. Though several States quarried a far higher tonnage, only in Massachusetts was the output as valuable. The reason is that 95% of the Vermont granite is used for monumental and ornamental purposes. The chief quarrying centre is at Barre. Of the 1,161,684 cu.ft. quarried in this district 232,336 cu.ft. were shipped out rough and 929,348 cu.ft. were cut and polished in the district.

In 1925 and 1926 Vermont produced almost double the amount of marble quarried in any other State. The output was 147,720 and 172,750 short tons, respectively, valued at $5,104,067 and $5,116,290. This was more than one-fourth the total output of the United States in quantity and more than one-third in value. The quarries lie in the eastern part of Rutland county.

The main slate belt is also in Rutland county along the western border, the area running into New York State. In Vermont a large variety of colours is found, various greens, purples, variegated, mottled and freak colours, all of which command high prices. In 1926 the value of the slate output was $4,267,041, and in 1927, $4,108,911. Vermont produced 34·5% of the total slate output of the United States in 1926 and 36% in 1927.

Vermont produces talc and soapstone, being second only to New York in 1926, but the output is not of as high grade as in some other States. The production in 1926 was 53,510 short tons, valued at $514,527. Both crude and ground talc was sold.

Manufacturing.—From 1900 to 1914 manufacturing increased but slowly, the value of products in the latter year being $76,990,974. But during the years of the World War expansion was rapid, and in 1919 products amounted in value to $168,108,000, the industry employing 33,491 wage-earners. After the war there was a sudden period of depression and in 1921 but 25,767 wage-earners were retained and the value of their products had dropped to $113,904,000. In 1925 there were 951 manufacturing establishments, 150 less than in 1921, employing 27,563 wage-earners, to whom $32,326,000 was paid in wages, and producing goods valued at $138,326,000, of which $67,878,000 was added by the manufacturing processes. The leading industries in 1925 follow:

Industry	Establishments	Wage-earners	Value of products
Marble, slate and stone work	211	4,651	$18,396,000
Woollen goods	16	2,933	14,327,000
Paper and wood pulp	17	1,387	9,744,000
Flour, feed and other grain mill products	45	192	8,368,000
Butter, cheese, condensed and evaporated milk	84	306	8,074,000
Metal-working machinery	6	1,159	6,673,000
Lumber and timber products	151	2,214	6,140,000
Knitted goods	8	1,257	5,638,000

Burlington, Barre, Rutland, Bennington, Brattleboro, St. Johnsbury, Springfield, Proctor, Winooski, St. Albans and Bellows Falls are the chief manufacturing centres.

Transportation.—There has been no railway building since 1910, in which year the mileage was 1,100. In 1925 the mileage was 1,057. The chief railways are two main lines which run north and south along the western and eastern borders, and four lines which cross the State in a general east and west direction. To cross from west to east at other places is impossible by rail, and there is some difficulty in getting from the south-west corner to points along the Connecticut river toward the north-east. The lack of railway facilities has been overcome to an agreeable extent since 1923 by the establishment of motor-bus lines on many of the main highways, and to villages not on the railway lines. There were 4,462 m. of road in the State highway system in 1927, of which 3,139 m. was surfaced. Expenditures on the State highway in 1925, including Federal aid, amounted to $3,618,000.

A canal connects the head of Lake Champlain with the Hudson river so that through Lake Champlain and its outlet, the Richelieu river, there is an uninterrupted waterway from the St. Lawrence river to New York city harbour, a waterway that is open for navigation at least seven months each year. The Chambly canal around the Chambly rapids of the Richelieu river permits the passage of boats. On Lake Champlain there are both passenger and freight lines which regularly serve the chief towns of the lake.

History.—The first white man to visit the region now known as Vermont, so far as the records show, was Samuel Champlain, "Father of New France." Joining an Algonquin war party, on a foray into the Iroquois country, July 4, 1609, he entered the lake which he named Lake Champlain. For well nigh a century and a half the Champlain valley was French territory. The increase of the Iroquois compelled the French in Canada to erect a chain of forts to command the approach by way of Lake Champlain and its outlet, the Richelieu river, the great trunk line highway from the valley of the St. Lawrence river to southern New England and the Hudson valley. As the English settlements in Massachusetts and adjacent colonies grew stronger, the Indians gradually withdrew into Canada, and, sullen and revengeful, were ready to join the French in raids upon the English settlements.

The first permanent English settlement was a blockhouse erected in 1724, in the town of Brattleboro, and known as Ft. Dummer. Later in the same year a group of Dutch squatters settled in the town of Pownal, in the south-western corner of Vermont. But not until the British captured Canada, in 1760, did the tide of emigration flow into the State. Benning Wentworth, royal governor of New Hampshire, assuming that the rather vague limits of his province, like those of Connecticut and Massachusetts, extended westward to a line 20 m. east of the Hudson river, proceeded to make grants of land between the Connecticut river and Lake Champlain. From 1749 to 1764 he granted 131 townships and the region was commonly known as the New Hampshire Grants. Lieutenant Governor Colden of New York challenged the right of the New Hampshire executive to grant these lands. For 14 years the ownership of the disputed region was debated and on July 20, 1764, an order of the king in council gave a decision in favour of New York. Thereupon the New York governors proceeded to grant lands in what is now the

State of Vermont.

Following the close of the French and Indian War and prior to the outbreak of the American Revolution, several thousand persons, largely from Connecticut and Massachusetts, had purchased lands in the New Hampshire Grants, had cleared farms, built houses and planted crops. In 1770 a test case was brought in the New York courts, in an ejectment suit, concerning property in the town of Shaftsbury, and the court refused to consider the New Hampshire charter as evidence. Ethan Allen, in charge of the defence, returned to Bennington, where the town voted to protect its rights by force if necessary. A military organization was formed, which came to be known as the Green Mountain Boys, Ethan Allen being its commander. In eastern Vermont New York authority was recognized, and no attempt was made to dispossess settlers, but in western Vermont New York authority was successfully defied. New Hampshire titles were defended.

With the Revolution the Green Mountain Boys, commanded by Ethan Allen, with some aid from Connecticut and Massachusetts, on May 10, 1775, captured the fortress of Ticonderoga, on Lake Champlain. The capture was the first aggressive act on the part of the Americans in the Revolutionary War. Vermonters participated in the invasion of Canada in the autumn of 1775, and Ethan Allen was captured by the British in an unsuccessful attempt to take Montreal.

A rudimentary form of government was maintained through committees of safety. Conventions were held in 1776 looking toward statehood, Ira Allen being active in behalf of a separate government. On Jan. 16, 1777, a declaration of independence was adopted and the name New Connecticut was given the new State. This name was soon abandoned, as it had been used elsewhere, and the name Vermont was substituted. In July 1777, a State Constitution was drafted in a convention held at Windsor. This was the first Constitution adopted by an American State to forbid slavery and to establish manhood suffrage. The new State government was set up in March 1778, with Thomas Chittenden as governor.

The British under Gen. Burgoyne captured the Lake Champlain forts in July 1777, and the rear guard of the American army, retreating from Ticonderoga, was defeated at Hubbardton, Vt., July 7, 1777. In an attempt to capture American stores at Bennington, British detachments under Cols. Baum and Breymann were defeated by an American force, consisting of Vermont, New Hampshire and Massachusetts troops commanded by Gen. John Stark, on Aug. 16, 1777. This was the beginning of Burgoyne's reverses which ended in his surrender to Gen. Gates.

The new State of Vermont continued to function, although opposed by foes at home and abroad. In 1790 New York, under the leadership of Alexander Hamilton, recognized the independence of Vermont conditioned upon the payment of $30,000, and on Mar. 4, 1791, the Green Mountain Commonwealth was the first State admitted to the Union after the original 13.

Settlement was rapid during the latter years of the Revolutionary War. A rough census showed about 7,000 people in the State in 1771. In 1791 the number rose to 85,525. After her declaration of independence the State granted her own lands. In 1779 the legislature planned that they were to be in townships 6 m. square with 70 rights or divisions in each. Five divisions in each were reserved, one for the support of a college, one for a county grammar school, one for an English school, one for the support of preaching and one for the first settled minister. The legislature convened in several of the larger towns of the State until 1808, when the capital was permanently situated at Montpelier.

Many little iron mines were opened, and small forges put in operation with charcoal as fuel. This was an industry which is no longer found. The iron and other businesses were stimulated by the War of 1812. In this war Vermont troops took part in the battles of Chippewa, Lundy's Lane, Lake Erie and Plattsburgh, but the only engagement in the State itself was the defence of Ft. Cassin at the mouth of Otter creek in 1813.

Steady expansion followed. Farm produce and cattle were sold South to older markets. The lumber business began to be developed in the Connecticut valley and along the shores of Lake Champlain where water transportation was available, the demand at first being principally for ship timber. During the winter the lines of sledges took the produce of the Champlain region to Montreal, just as that from the south-western part was taken to Albany, and that from the Connecticut valley to Portsmouth or Boston. The opening of the Champlain canal in 1823, connecting Lake Champlain and the Hudson river, largely increased commerce with New York and diverted trade from Canada. Stage lines began to carry the mail and passengers throughout the State. Many towns to which they went had a larger population in 1820 than in 1920. The decade between 1820 and 1830 was the last one in which there was a marked increase of population in the State. After that many Vermonters were seized with the desire to go west and so they helped to build many of the northern States of the Mississippi valley. Many also went south to the rising industrial centres of Massachusetts and Connecticut. Despite these great losses the population continued to increase, aided in later years by an influx of French Canadians from Canada.

During the Civil War a small band of Confederates crossed the frontier from Canada and raided the town of St. Albans. In 1870 St. Albans was the headquarters of an attempted Fenian invasion of Canada. Sheep raising was an important farm industry before and after the Civil War, but after 1880 declined rapidly because of competition from the Western States and Australia. The Vermont Central, between Windsor and Burlington, and the Rutland from Bellows Falls to Burlington, were completed in 1849. In presidential campaigns the State was Federalist, 1792–1800; Democratic-Republican, 1804–20; Adams-Republican, 1824–28; Anti-Masonic, 1832; Whig, 1836–52; and Republican since 1856.

BIBLIOGRAPHY.—M. D. Gilman, *Bibliography of Vermont* (1897) approaches completeness for the period before the date of its publication. For physical description, geology and minerals the many papers in the annual *Reports of the State Geologist* are most valuable. For education *see* G. G. Bush, *History of Education in Vermont* (1900) and *Vermont Educational Commission Report* (1914).

Of the older histories the more famous are: I. Allen, *Natural and Political History of the State of Vermont* (1798, reprinted in Vermont Historical Collections, 1870); S. Williams, *Natural and Civil History of Vermont* (2nd ed., 1809); Z. Thompson, *History of Vermont, Natural, Civil and Statistical* (1848); B. H. Hall, *History of Eastern Vermont to the Close of the Eighteenth Century* (2nd ed., 1865); H. Hall, *History of Vermont from its Discovery to its Admission into the Union in 1791* (1868); A. M. Hemenway (ed.), *Vermont Historical Gazetteer* (5 vol., 1867–91). R. E. Robinson, *Vermont* (1892), in the "American Commonwealths" series is based largely on the above works but is more readable and more easily secured. *History of Vermont* in 5 volumes, by Walter H. Crockett was published 1921–23. An excellent high school text is E. D. Collins, *History of Vermont* (rev. ed., 1916). *See* also W. Nutting, *Vermont Beautiful* (1922); Vermont Bureau of Publicity, *Vermont the Land of Green Mountains* (1913); H. Hall, *Ethan Allen* (1892); J. B. Wilbur, *Ira Allen, Founder of Vermont* (2 vol., 1928); F. Parkman, *A Half Century of Conflict* (1892) and *Montcalm and Wolfe* (1884); Champlain Society, *Works of Samuel de Champlain* (3 vol., 1922–25); Vermont Historical Society, *Collections* (1870–71) and *Proceedings* (various dates between 1860 and 1925); *The Vermonter* (1897 *seq.*). VERMOREL, AUGUSTE JEAN MARIE (1841–1871), French journalist, was born at Denicé, France, on June 20, 1841. A radical and socialist, he was attached to the staff of the *Presse* (1864) and the *Liberté* (1866); in 1866 he became editor of the *Courrier Français* and in 1869 of *La Réforme*, being twice imprisoned. He took an active part in the Commune, and was dangerously wounded while fighting at the barricades. He died a prisoner at Versailles, on June 20, 1871.

VERMOUTH. An alcoholic beverage, the basis of which consists of white wine. The wine is fortified with spirit up to a strength of about 15% of alcohol, and is then stored in casks exposed to the sun's rays for a year or two. Another portion of the wine is fortified up to a strength of about 50% of alcohol, and in this various aromatic and tonic materials are macerated in casks which are exposed to the sun in the same way as the bulk of the wine. The two liquids are then mixed in such proportions as to make the strength of the ultimate product about 17% of alcohol by volume. Italian vermouth is sweet in taste and darker than the dry French vermouth.

VERNE, JULES (1828–1905), French author, was born at Nantes on Feb. 8, 1828. After completing his studies at the

Nantes lycée, he went to Paris to study law. About 1848, in conjunction with Michel Carré, he wrote librettos for two operettas, and in 1850 his verse comedy, *Les Pailles rompues*, in which Alexandre Dumas fils had some share, was produced at the Gymnase. For some years his interests alternated between the theatre and the bourse, but some travellers' stories which he wrote for the *Musée des Familles* revealed to him the true direction of his talent—the delineation, viz., of delightfully extravagant voyages and adventures, in which he foresaw, with marvellous vision, the achievements of scientific and mechanical invention of the generation of 1900. "For the last twenty years," said Marshal Lyautey, "the advance of the peoples is merely living the novels of Jules Verne." Verne was a real pioneer in the wide literary genre of *voyages-imaginaires*. His first success was obtained with *Cinq semaines en ballon*, which he wrote for Hetzel's *Magazin d'Éducation* in 1862, and thenceforward, for a quarter of a century, scarcely a year passed in which Hetzel did not publish one or more of his amazing stories. The most successful include: *Voyage au centre de la terre* (1864); *De la terre à la lune* (1865); *Vingt mille lieues sous les mers* (1869); *Les Anglais au pôle nord* (1870); and *Voyage autour du monde en quatre-vingts jours*, which first appeared in *Le Temps* in 1872. The adaptation of this last (produced with immense success at the Porte St. Martin theatre on Nov. 8, 1874) and of another excellent tale, *Michael Strogoff* (at the Châtelet, 1880), both written in conjunction with Adolphe d'Ennery, proved the most acceptable of Verne's dramas.

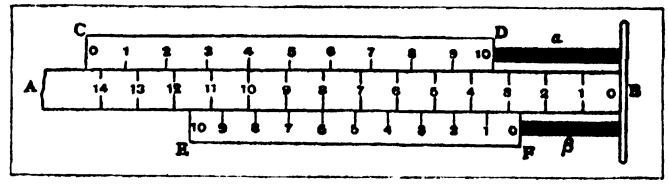
His novels delight by reason of their sparkling style, their picturesque *verve*—inherited from Dumas—their good-natured national caricatures, and the ingenuity with which the love element is subordinated. He was a member of the Legion of Honour, and several of his romances were crowned by the French Academy, but he was never enrolled among its members. He died at Amiens on March 24, 1905. The novels of Jules Verne are dreams come true, dreams of submarines, aeroplanes, television; they look forward, not backward. Therefore they are still the books of youth.

See C. Lemire, *Jules Verne, 1828–1925* (1908); M. Allotte de la Fuÿe, *Jules Verne, sa vie et son oeuvre* (1928).

VERNET, the name of three eminent French painters.

I. Claude Joseph Vernet (1714–1789), who was born at Avignon on Aug. 14, 1714, when only fourteen years of age aided his father, a skilful decorative painter. The sight of the sea at Marseilles and his voyage thence to Civita Vecchia made a deep impression on him, and immediately after his arrival he entered the studio of a marine painter, Bernardino Fergioni. For twenty years Vernet lived on in Rome, producing views of seaports, storms, calms, moonlights, etc., when he was recalled (1753) to Paris, and executed, by royal command, the remarkable series of the seaports of France (Louvre) by which he is best known. He died Dec. 3, 1789.

II. Antoine Charles Horace Vernet (1758–1835), commonly called Carle, the youngest child of the above, was born at Bordeaux in 1758. His first important work, was his "Triumph of Paulus Aemilius"; in this picture he broke with reigning traditions in classical subjects, and drew the horse with the forms he had learnt from nature in stables and riding-schools. The Revolution, and his sister's death on the scaffold, stopped his artistic career. When he again began to produce, it was as the man of another era: his drawings of the Italian campaign brought him fresh laurels; his vast canvas, the "Battle of Marengo," obtained great success; and for his "Morning of Austerlitz" Napoleon bestowed on him the Legion of Honour. His hunting-pieces, races, landscapes, and work as a lithographer (chiefly under the Restoration) had a great vogue. In 1827 he accompanied his son Horace (*see* below) to Rome, and died in Paris on his return, on Nov. 17, 1835.



III. Horace Vernet (1789–1863), born in Paris on June 30, 1789, was one of the most characteristic of the military painters of France. He was just twenty when he exhibited the "Taking of an Entrenched Camp"—a work which showed no depth of observation, but was distinguished by a good deal of character. His picture of his own studio (the rendezvous of the Liberals under the Restoration), in which he represented himself painting tranquilly, whilst boxing, fencing, drum- and horn-playing, etc., were going on, in the midst of a medley of visitors, horses, dogs and models, is one of his best works, and, together with his "Defence of the Barrier at Clichy" (Louvre), won for him an immense popularity. He was appointed director of the school of France at Rome, from 1828 to 1835, and thither he carried the atmosphere of racket in which he habitually lived. After his return the whole of the Constantine room at Versailles was decorated by him in the short space of three years. He died at Paris on Jan. 17, 1863.

See Lagrange, *Joseph Vernet et la peinture au XVIIIe siècle* (1861); C. Blanc, *Les Vernet* (1845); A. Dayot, *Les Vernet* (1898).

VERNEUIL, a town of north-western France. Pop. (1926) 3,551. Verneuil stands on the left bank of the Avre. The church of La Madeleine (11th to 17th century) has the façade flanked by a square tower of the first half of the 16th century. The church contains old stained glass, an ironwork pulpit and other works of art. The church of Notre Dame (12th and 16th centuries) possesses Romanesque stone carvings. The Tour Grise is a cylindrical keep built in 1120 by Henry I.

VERNIER, PIERRE (*c.* 1580–1637), inventor of the instrument which bears his name, was born at Ornans (near Besançon) in Burgundy about 1580. He was for a considerable time commandant of the castle in his native town. In 1631 he published at Brussels a treatise entitled *Construction, usage et propriétés du quadrant nouveau de mathématiques*, in which the instrument associated with his name is described. He died at Ornans in 1637.

VERNIER INSTRUMENT, a measuring device which enables either linear or angular magnitudes to be read with a degree of accuracy many times greater than is possible with a scale as ordinarily divided and subdivided. The principle of the vernier is readily understood from the following figure and illustration.

Let AB (*see* fig.) be the normal scale, *i.e.* a scale graduated according to a standard of length, CD, a scale (placed in contact with AB for convenience) graduated so that 10 divisions equal 11 divisions of the scale AB, and EF a scale placed similarly and graduated so that 10 divisions equal 9 divisions of the scale AB. Consider the combination AB and CD. Obviously each division of CD is $\frac{1}{10}$th greater than the normal scale division. Let α represent a length to be measured, placed so that one end is at the zero of the normal scale, and the other end in contact with the end of the vernier CD marked 10. It is noted that graduation 4 of the vernier coincides with a division of the standard, and the determination of the excess of α over 3 scale divisions reduces to the difference of 7 divisions of the normal scale and 6 divisions of the vernier. This is ·4, since each vernier division equals 1·1 scale divisions. Hence the scale reading of the vernier which coincides with a graduation of the normal scale gives the decimal to be added to the normal scale reading. Now consider the scales AB and EF, and let β be the length to be measured; the scale EF being placed so that the zero end is in contact with an end of β. Obviously each division of EF is $\frac{1}{10}$th less than that of the normal scale. It is seen that division 6 of the vernier coincides with a normal scale division, and obviously the excess of β over two normal scale divisions equals the difference between 6 normal scale divisions and 6 vernier divisions, *i.e.* 0·6. Thus again in this case the vernier reading which coincides with a scale reading gives the decimal to be added to the normal scale. The second type of vernier is that more commonly adopted, and its application to special appliances is quite simple.

VERNIS MARTIN, a generic name, derived from a distinguished family of French artist-artificers of the 18th century, given to a brilliant translucent lacquer extensively used in the decoration of furniture, carriages, sedan chairs and a multitude of small articles such as snuff-boxes and fans. There were four brothers of the Martin family: Guillaume (d. 1749), Simon Étienne, Julien and Robert (1706–1765), the two first named being the elder. They were the children of Étienne Martin, a tailor, and began life as coach-painters. They neither invented, nor claimed to have invented, the varnish which bears their

name, but they enormously improved, and eventually brought to perfection, compositions and methods of applying them which were already more or less familiar. Oriental lacquer speedily acquired high favour in France, and many attempts were made to imitate it. Some of these attempts were passably successful, and we can hardly doubt that many of the examples in the possession of Louis XIV. at his death were of European manufacture. Chinese lacquer was, however, imported in large quantities, and sometimes panels were made in China from designs prepared in Paris, just as English coats of arms were placed upon Chinese porcelain in its place of origin. At the height of their fame the brothers directed at least three factories in Paris, and in 1748 they were all classed together as a "Manufacture nationale." One of them was still in existence in 1785. The literature of their day had much to say of the frères Martin. In Voltaire's comedy of *Nadine,* produced in 1749, mention is made of a *berline* "bonne et brillante, tous les panneaux par Martin sont vernis"; also in his *Premier discours sur l'inégalité des conditions* he speaks of "des lambris dorés et vernis par Martin." The marquis de Mirabeau in *L'Ami des hommes* refers to the enamelled snuff-boxes and varnished carriages which came from the Martins' factory. At its best Vernis Martin has a splendour of sheen, a perfection of polish, a beauty of translucence which compel the admiration due to a consummate specimen of handiwork. Every variety of the lacquer of the Far East was imitated and often improved upon by the Martins—the black with raised gold ornaments, the red, and finally in the wonderful green ground, powdered with gold, they reached the high-water mark of their delightful art. Of the larger specimens from the Martins' factories a vast quantity has disappeared, or been cut up into decorative panels. It would appear that none of the work they placed in the famous hotels of old Paris is now *in situ,* and it is to museums that we must go for really fine examples—to the Musée de Cluny for an exquisite children's sedan chair and the coach used by the French ambassador to Venice under Louis XV.; to the Wallace collection for the tables with richly chased mounts that have been attributed to Dubois; to Fontainebleau for a famous commode. It has been generally accepted that of the four brothers Robert Martin accomplished the most original and the most completely artistic work. He left a son, Jean Alexandre, who described himself in 1767 as "Vernisseur du Roi de Prusse." He was employed at Sans Souci, but failed to continue the great traditions of his father and his uncles. The Revolution finally extinguished a taste which had lasted for a large part of the 18th century. Since then the production of lacquer has, on the whole, been an industry rather than an art. (J. P.-B.)

VERNON, EDWARD (1684–1757), English admiral, was born in Westminster on Nov. 12, 1684, the second son of James Vernon, secretary of State in 1697–1700. Edward Vernon entered the navy in 1707, and saw much active service in various seas. During the long peace under Walpole he sat in the House of Commons (1722–34); he clamoured for war with Spain, and in 1739 declared he would capture Portobello with a squadron of six ships. He got the command and the ships and captured Portobello on Nov. 22, with a loss of only seven men. In 1740, with a large squadron, he attacked Cartagena without success, and had to retire to Jamaica (this episode is described in *Roderick Random,* chap. xiii., etc.). Vernon suffered another reverse at Santiago de Cuba in 1741, and returned home in 1743. He had been elected M.P. for Ipswich in 1741, and continued to sit for that borough. He was in command in the Downs in 1745, but in annoyance at intervention from Whitehall he published some of his instructions, and was struck off the flag list. He died on Oct. 30, 1757, at Nacton, Suffolk.

VERNON, a town of north-western France. Pop. (1926) 7,887. Vernon in 1196 was ceded by its count to Philip Augustus, Richard I. resigning his suzerainty. The first Estates of Normandy were held at Vernon in 1452. Vernon stands on the left bank of the Seine. The church of Notre-Dame is an interesting building dating from the 12th to the 15th centuries, and there is a cylindrical keep built by Henry I. of England.

VERNON, a city of northern Texas, U.S.A., on the Pease river, the county seat of Wilbarger county. The population was 5,142 in 1920 (95% native white) and was estimated at 15,000 in 1928. It is the shipping point for a wide region (producing cotton, wheat, alfalfa and cattle), and for oil-wells with a daily production (1928) of 35,000 barrels. Vernon was settled about 1880, incorporated in 1901, and chartered as a city in 1914.

VEROLI, an episcopal see of the province of Rome, Italy, 1,870 ft. above sea-level. Pop (1921) 4,676 (town); 15,096 (commune). The town is situated on the site of the Hernican town of Verulae. It retains remains of its ancient polygonal enceinte, especially near the summit of the hill, later occupied by a mediaeval castle. The cathedral treasury contains the breviary of S. Louis of Toulouse.

VERONA, a city and episcopal see of Venetia, Italy, the capital of the province of Verona, situated 194 ft. above sea-level in a loop of the Adige (anc. *Athesis*). Pop. (1921) 87,342 (town), 92,536 (commune). It is the point of departure to the Brenner.

Churches.—The Romanesque basilica of S. Zeno (the first bishop of Verona and its patron saint), outside the ancient city, was remodelled in 1117–38, including the richly sculptured west front and the open *confessio* or crypt, raising the choir high above the nave. The nave (11th century) has frescoes of the 11th–14th centuries.

The cathedral, consecrated in 1187, stands at the northern end of the ancient city, by the bank of the Adige; it is smaller than S. Zeno, but has a fine west front, rich with Romanesque sculpture (1135); the upper part was added during 1565–1606. It has a noble Romanesque cloister, with two storeys of arcading. The campanile by Sammicheli is unfinished. Its baptistery, rebuilt early in the 12th century, is a quite separate building, with nave and apse, forming a church dedicated to S. Giovanni in Fonte. Pope Lucius III. (d. 1185) is buried in the cathedral. The very fine Gothic Dominican church of S. Anastasia (1290–1481), consists of a nave in six bays, aisles, transepts, each with two eastern chapels, and an apse, all vaulted with simple quadripartite brick groining. It is specially remarkable for its very beautiful and complete scheme of coloured decoration. The vaults are gracefully painted with floreated bands along the ribs and central patterns in each "cell," in rich soft colours on a white plastered ground. There are many fine frescoes in the interior including Pisanello's beautiful painting of St. George. This church also contains fine sculptured tombs of the 14th and 15th centuries. S. Fermo Maggiore was rebuilt in 1313 at a higher level than the earlier church (1065–1138). The roof is magnificent. Delicate patterns cover all the framework of the panelling and fill the panels themselves. Rows of half-figures of saints are painted on blue or gold grounds, forming a scheme of indescribably splendid decoration. A simpler roof of the same class exists at S. Zeno; it is trefoil-shaped in section, with a tie-beam joining the cusps. The church of S. Maria in Organo (1481), with a façade of 1592 from Sammicheli's designs, contains paintings by various Veronese masters, and some fine choir-stalls of 1499 by Fra Giocondo. Though not built till after his death, the church of S. Giorgio di Braida, on the other side of the river, was also designed by Sammicheli, and possesses many good pictures of the Veronese school. The Romanesque churches of S. Lorenzo and S. Stefano are fine. That dedicated to Thomas Becket was rebuilt in the 15th century.

The strongly fortified castle (Castel Vecchio) built by Cangrande II. della Scala (1354) stands on the line of the wall of Theodoric, close by the river. It contains the municipal museum and picture gallery. There are five bridges across the Adige: one, the graceful Ponte di Pietra, rests upon ancient foundations, while the two arches nearest to the left bank are Roman; but it has been frequently restored. Remains of another ancient bridge were found in the river itself behind S. Anastasia. The 16th-century lines of fortification enclose a very much larger area than the Roman city. On a steep elevation stands the castle of St. Peter, originally founded by Theodoric, on the site, perhaps, of the earliest citadel, mostly rebuilt by Gian Galeazzo Visconti in 1393, and dismantled by the French in 1801. The episcopal palace contains the ancient and valuable chapter library, of about 12,000 volumes and over 500 mss. (*See* GAIUS.) The Piazza delle Erbe

(fruit and vegetable market) on the site of the ancient Forum and the Piazza dei Signori, adjoining one another in the oldest part of the city, are very picturesque and beautiful, being surrounded by many fine mediaeval buildings, notably the Palazzo del Comune, with a tower 273 ft. high, while in the north-east corner of the latter Piazza is the fine early Renaissance Loggia del Consiglio (1476–1493), most likely designed by Fra Giocondo. The Piazza Vittorio Emanuele II. (also called Bra, from the Latin *pratum*, a meadow) to the south-west of the amphitheatre, is the tramway centre and the site of the cattle market. On it fronts the Gran Guardia, a large palace of 1610, now the Bourse.

Roman Remains.—The Roman remains of Verona surpass those of any other city of northern Italy. The most conspicuous of them is the great amphitheatre, a building of the end of the 1st century A.D., which closely resembled the Flavian amphitheatre (Colosseum) in Rome. Its axes measured 505 and 404 ft. Almost the whole of its external arcades, with three tiers of arches, have now disappeared; it was partly thrown down by an earthquake in 1183, and subsequently used to supply building materials. The interior, with seats for about 25,000 people, has been restored. There are also remains of a well-preserved Roman theatre, close to the left bank of the river adjacent to which is the archaeological museum. The Museo Lapidario contains a fine collection of Roman and Etruscan inscriptions and sculpture, begun by Scipione Maffei in 1714.

Veronese Art, Painting and Sculpture.—Painting in Verona may be divided into four periods. (i.) The first is characterized by wall paintings of purely native style, *e.g.*, in SS. Nazaro e Celso (996). (ii.) The Byzantine period lasted during the 12th and 13th centuries. (*See* S. Zeno for examples.) (iii.) The Giottesque period begins contemporaneously with Altichieri and Giacomo d'Avanzo (second half of the 14th century). These two painters, among the ablest of Giotto's followers, adorned Verona and Padua with very beautiful frescoes, rich in composition, delicate in colour, and remarkable for their highly finished modelling and detail. (iv.) To the fourth period belong several important painters. Pisanello or Vittore Pisano, a charming painter and the greatest medallist of Italy, probably a pupil of Altichieri, has left a beautiful fresco in the church of S. Anastasia, representing St. George and the Princess after the conquest of the Dragon. His only other existing fresco is an Annunciation in S. Fermo Maggiore. (*See* PAINTING.) His pupils include Liberale da Verona, Domenico and Francesco Morone, Girolamo dai Libri (1474–1556), etc. Domenico del Riccio, usually nicknamed Brusasorci (1494–1567), was a prolific painter whose works are very numerous in Verona. Paolo Cagliari or Paul Veronese, and Bonifacio, though natives of Verona, belong rather to the Venetian school.

Verona is specially rich in early examples of decorative sculpture. (i.) The first period is that of northern influence, exemplified in the reliefs which cover the western façades of the church of S. Zeno and the cathedral, dating from the 12th century, and representing both sacred subjects and scenes of war and hunting, mixed with grotesque monsters. Part of the western doors of S. Zeno are early examples of caste bronze reliefs. (ii.) In the 13th century the sculpture lost its vigour, without acquiring grace or refinement, *e.g.*, the font in the cathedral baptistery. (iii.) The next period is that of Florentine influence, exemplified in the magnificently sculptured tombs of the Della Scala lords, those of Cangrande I. (d. 1329), Mastino II. (d. 1351) and (the most elaborate of all) of the fratricide Can Signorio, adorned with statuettes of the virtues, executed during his lifetime (*c.* 1370), by the sculptor Bonino da Campione. (iv.) In the 15th century Florence influenced Verona by way of Venice.

Architecture.—The architecture of Verona, like its sculpture, passed through Lombard, Florentine and Venetian stages. The early Renaissance developed into very exceptional beauty, mainly through the genius of Fra Giocondo (1435–1514), a native of Verona, who was at first a friar in the monastery of S. Maria in Organo. He rose to great celebrity as an architect, and designed many graceful and richly sculptured buildings in Venice, Rome and even in France; he used classical forms with great taste and skill, and with much of the freedom of the older mediaeval architects, and was specially remarkable for his rich and delicate sculptured decorations. Another of the leading architects of the next stage of the Renaissance was the Veronese Michele Sammicheli (1484–1559), a great military engineer, and designer of an immense number of magnificent palaces in Verona, among which the most outstanding are the Bevilacqua, Canossa and Pompei palaces.

History.—The ancient Verona was a town of the Cenomani, a Gaulish tribe, whose chief town was Brixia. It became a Latin colony in 89 B.C. Inscriptions testify to its importance, indicating that it was the headquarters of the collectors of the 5% inheritance tax under the Empire in Italy beyond the Po. Its territory stretched as far as Hostilia on the Padus (Po), 30 m. to the south. It lay on the road between Mediolanum and Aquileia, while here diverged to the north the roads over the Brenner. It was the birthplace of the poet Catullus. In A.D. 69 it became the headquarters of the legions which were siding with Vespasian. It was defended by a river along two-thirds of its circumference. The existing remains of walls and gates date from the period between the 3rd of April and the 4th of December of the year 265. A very handsome triumphal arch, now called the Porta de' Borsari, was restored in this year by Gallienus and became one of the city gates. The same was the case with the Porta dei Leoni, on the east of the city, and with a third arch, the Arco dei Gavi, demolished in 1805. The emperor Constantine, while advancing towards Rome from Gaul, besieged and took Verona (312); it was here, too, that Odoacer was defeated (499) by Theodoric the Goth, Dietrich von Bern—*i.e.*, Verona—of German legends, who built a castle at Verona and frequently resided there. He enlarged the fortified area by constructing a wall and ditch (now called Adigetto), to the S.W. of the amphitheatre, and also built thermae and restored the aqueducts, which had long been out of use.

In the middle ages Verona gradually grew in size and importance. Alboin, the Lombard king, captured it in 568, and it was one of the chief residences of the Lombard, and later of the Frankish, monarchs; and though, like other cities of northern Italy, it suffered much during the Guelph and Ghibelline struggles, it rose to a foremost position both from the political and the artistic point of view under its various rulers of the Scaliger or Della Scala family. The first prominent member of this family and founder of his dynasty was Mastino I. della Scala, who ruled over the city from 1260 till his death in 1277. Verona had previously fallen under Ezzelino da Romano (1227–1259). Alberto della Scala (d. 1301) was succeeded by his eldest son Bartolomeo, who was confirmed as ruler of Verona by the popular vote, and died in 1304. It was in his time that Romeo and Juliet are said to have lived. Alboino, the second son, succeeded his brother, and died in 1311, when the youngest son of Alberto, Can Grande, who since 1308 had been joint-lord of Verona with his brother, succeeded to the undivided power. Can Grande (Francesco della Scala, d. 1329) was the best and most illustrious of his line, and is specially famous as the hospitable patron of Dante (*q.v.*). Other princes of this dynasty, which lasted for rather more than a century, were Giovanni (d. 1350), Mastino II. (d. 1351), Can Grande II. (d. 1359) and Can Signorio (d. 1375). In 1387 Gian Galeazzo Visconti, duke of Milan, became by conquest lord of Verona. Soon after his death the city fell by treacherous means into the hands of Francesco II. di Carrara, lord of Padua. In 1404–1405 Verona, together with Padua, was finally conquered by Venice, and remained subject to the Venetians till the overthrow of the republic by Napoleon in 1797, who in the same year, after the treaty of Campo Formio, ceded it to the Austrians with the rest of Venetia. They fortified it strongly in 1814, and with Peschiera, Mantua and Legnago it formed part of the famous quadrilateral which until 1866 was the chief support of their rule in Italy. The town was greatly damaged by a flood in 1882.

VERONA, CONGRESS OF, the last of the series of international conferences or congresses based on the principle enunciated in Art. 6 of the treaty of Paris of Nov. 20, 1815 (*see* EUROPE, *History*). It met at Verona on Oct. 20, 1822. The emperor Alexander I. of Russia was present in person. There were also present Count Nesselrode, the Russian minister of foreign affairs; Prince Metternich, representing Austria; Prince Hardenberg and Count Bernstorff, representing Prussia; MM. de Montmorency and Chateaubriand, representing France; and the duke of Wellington, representing Great Britain.

The immediate problems arising out of the Turkish Question had been settled between the emperor Alexander and Metternich, at the preliminary conferences held at Vienna in September, and at Verona the only question raised was that of the proposed French intervention in Spain. The discussion was opened by three questions formally propounded by Montmorency: (1) Would the Allies withdraw their ministers from Madrid in the event of France being compelled to do so? (2) In case of war, under what form and by what acts would the powers give France their moral support, so as to give to her action the force of the Alliance, and inspire a salutary fear in the revolutionaries of all countries? (3) What material aid would the powers give, if asked by France to intervene, under restrictions which she would declare and they would recognize?

The reply of Alexander, who expressed his surprise at the desire of France to keep the question "wholly French," was to offer to march 150,000 Russians through Germany to Piedmont, where they could be held ready to act against the Jacobins whether in Spain or France. Wellington, who had been instructed to express the uncompromising opposition of Great Britain to the whole principle of intervention, refused to have anything to do with the suggestion, made by Metternich, that the powers should address a common note to the Spanish Government in support of the action of France. Finally, Metternich proposed that the Allies should "hold a common language, but in separate notes, though uniform in their principles, and objects." This solution was adopted by the continental powers; and Wellington, in accordance with his instructions, took no part in the conferences that followed. On Oct. 30 the powers handed in their formal replies to the French memorandum. Russia, Austria and Prussia would act as France should in respect of their ministers in Spain, and would give to France every countenance and assistance she might require, the details "being reserved to be specified in a treaty." Wellington, on the other hand, replied on behalf of Great Britain that "having no knowledge of the cause of dispute, and not being able to form a judgment upon a hypothetical case, he could give no answer to any of the questions."

Thus was proclaimed the open breach of Great Britain with the principles and policy of the Great Alliance, which is what gives to the congress its main historical interest. (W. A. P.)

VERONAL, a crystalline substance extensively used in medicine as a hypnotic. Chemically, veronal is diethylmalonyl urea or diethyl-barbituric acid $(C_2H_5)_2C[CO\ NH]_2CO$. It is prepared by condensing diethylmalonic ester with urea in the presence of sodium ethylate, or by acting with ethyl iodide on the silver salt of malonyl urea; it forms a white crystalline powder, which is odourless, and has a slightly bitter taste. Its introduction followed the investigations of Emil Fischer and J. v. Merling on the pharmacological properties of certain open and closed ureides. Led thereto by the impression that hypnotic action appears to be largely dependent on the presence of ethyl groups, they prepared diethylacetyl urea, diethylmalonyl urea, and dipropylmalonyl urea. All three were found to be hypnotics: the first was about equal in power to sulphonal, whilst the third was four times as powerful, but its use was attended by prolonged after-effects. Veronal was found to be midway. It is best given in cachets (10 to 15 grains). As it does not affect the circulatory or respiratory systems, or temperature, it can be employed in many diseased conditions of the heart and lungs as well as in mental disturbances, acute alcoholism, morphinomania and kidney disease. If taken during a prolonged period it seems to lose its effect. A soluble salt of veronal has been introduced under the name of medinal. Although the toxicity of veronal is low, the unreasonable consumption by persons suffering from insomnia has led to many deaths. (*See* BARBITURIC ACID.)

VERONICA, ST. According to legend, Veronica was a pious woman of Jerusalem, who gave Jesus her kerchief to wipe the drops of agony from His brow. After using the napkin He handed it back with the image of His face miraculously impressed upon it. Other legends identify her with the woman who had an issue of blood. Eusebius tells in his *Historia Ecclesiastica* (vii. 18) how outside this woman's house, at Caesarea Philippi, there stood two figures, one a supplicating woman, the other that of a man representing Christ. It was said that the group had been set up in recognition of the miraculous cure. In the West this woman was identified with Martha of Bethany; in the East she was called Berenike, or Beronike. Towards the 6th century the legend of the woman with the issue of blood became merged in the legend of Pilate, as is shown in the writings known in the middle ages as *Cura sanitatis Tiberii* and *Vindicta Salvatoris*. According to the former of these accounts Veronica caused a portrait of the Saviour to be painted. The emperor Tiberius, when sick, commanded the woman to bring the portrait to him, worshipped Christ and was cured. The legend continued to gather accretions, and a miraculous origin came to be assigned to the image. According to the legends in France, Veronica was married to Zaccheus, who had been converted by Christ, and went with him to Quiercy, where he became a hermit. She then joined Martial in his apostolic preaching. In the Bordeaux district Veronica is said to have brought relics of the Virgin to Sonlac, where she died and was buried. In the 12th century the image began to be identified with one at Rome, and in the popular speech the image, too, was called Veronica. It is interesting to note that the fanciful derivation of the same Veronica from the words *Vera icon* (εἰκών) "true image" —dates back to the *Otia Imperialia* (iii. 25) of Gervase of Tilbury (*fl.* 1211), who says: "Est ergo Veronica pictura Domini vera."

VERRALL, ARTHUR WOOLLGAR (1851–1912), British scholar, was born at Brighton on Feb. 5, 1851. Educated at Wellington college and Trinity college, Cambridge, he graduated in 1873, becoming fellow and tutor of his college. He wrote important studies on Horace, Martial, Statius, and a specially valuable one on Propertius. He published editions of many classical *Choephoroe* (1893). In 1895 appeared *Euripides the Rationalist*, followed by *Essays on Four Plays of Euripides* (1905) and on plays, especially the *Medea* (1881), *Agamemnon* (1899) and an edition of the *Bacchae* (1910). He was an original critic, and a frequent contributor to *The Classical Review* and other journals. In Feb. 1911 he was appointed to fill the new King Edward VII. professorship of literature at Cambridge. He died at Cambridge on June 18, 1912.

VERRES, GAIUS (*c.* 120–43 B.C.), Roman magistrate, notorious for his misgovernment of Sicily. It is not known to what *gens* he belonged. He at first supported Marius, but soon went over to Sulla who gave him land at Beneventum, and secured him against punishment for embezzlement. In 80, Verres was quaestor in Asia on the staff of Cn. Cornelius Dolabella, governor of Cilicia. The governor and his subordinate plundered in concert, till in 78 Dolabella had to stand his trial at Rome, and was convicted, mainly on the evidence of Verres, who thus secured a pardon for himself. He was praetor in 74, and was then sent as governor to Sicily, the richest of the Roman provinces. The people were for the most part prosperous and contented, but under Verres the island experienced more misery and desolation than during the time of the first Punic or the recent servile wars. The corn-growers and the revenue collectors were ruined by taxation and the cancelling of contracts; temples and private houses were robbed of their works of art; and the rights of Roman citizens were disregarded. Verres returned to Rome in 70, and in the same year, at the request of the Sicilians, Cicero prosecuted him. Verres

was defended by the most eminent of Roman advocates, Q. Hortensius. The court was composed exclusively of senators, some of whom might have been his personal friends. But the presiding judge, M'. Acilius Glabrio, was not corruptible. Verres tried to get the trial postponed till 69 when his friend Metellus would be the presiding judge, but in August Cicero opened the case. The effect of the first brief speech was so overwhelming that Hortensius refused to reply, and recommended his client to leave the country. He went to Massilia and lived there till 43, when he was proscribed by Antony, the reason alleged being his refusal to surrender some of his art treasures which Antony coveted.

VERRIO, ANTONIO (1639–1707), Italian painter, was born at Lecce, in the Neapolitan province of Terra di Otranto. In 1660 at Naples he executed a large fresco work "Christ Healing the Sick," for the Jesuit College. He subsequently went to France where at Toulouse he painted an altarpiece for the Carmelites. He was invited to England by Charles II. and employed in the decorating of Windsor Castle. Little of his work is now extant. He was a rapid painter, fertile in invention, and best at covering large surfaces in decorative frescoes. Charles II. named him "master gardener," gave him a lodge in Hyde Park and paid him lavishly. He was employed by James II. on Cardinal Wolsey's Tombhouse. He painted James and several of his courtiers in the hospital at Christ Church, London, and also executed a number of decorative frescoes at St. Bartholomew's Hospital. He was later employed by Lord Exeter at Burleigh and painted the large staircase at Hampton Court for King William. He was very successful but his work was often severely criticized by his contemporaries for gaudy colours, bad drawing and senseless composition. He died at Hampton Court on June 17, 1707.

VERRIUS FLACCUS, MARCUS (*c.* 10 B.C.), Roman grammarian and teacher, flourished under Augustus and Tiberius. He was a freedman, and his manumitter has been identified with Verrius Flaccus, an authority on pontifical law; but for chronological reasons the name of Veranius Flaccus, a writer on augury, has been suggested (Teuffel-Schwabe, *Hist. of Roman Lit.* 199, 4). He was summoned to court to bring up Gaius and Lucius, the grandsons of Augustus. He removed there with his whole school, and his salary was greatly increased on the condition that he took no fresh pupils. He died at an advanced age during the reign of Tiberius (Suetonius, *De Grammaticis,* 17), and a statue in his honour was erected at Praeneste, in a marble recess, with inscriptions from his *Fasti.* Flaccus was also a distinguished philologist and antiquarian investigator. For his most important work (*De Verborum Significatu*) *see* FESTUS, SEXTUS. Of the calendar of Roman festivals (*Fasti Praenestini*) engraved on marble and set up in the forum at Praeneste, some fragments were discovered (1771) at some distance from the town itself in a Christian building of later date, and some consular *fasti* in the forum itself (1778). Two new fragments were subsequently added.

Other lost works of Flaccus were: *De Orthographia: De Obscuris Catonis,* an elucidation of obscurities in the writings of the elder Cato; *Saturnus,* dealing with questions of Roman ritual; *Rerum memoria dignarum libri,* an encyclopaedic work much used by Pliny the elder; *Res Etruscae,* probably on augury.

VERROCCHIO, ANDREA DEL (1435–1488), Italian goldsmith, sculptor and painter, was born at Florence. He was the son of Michele di Francesco de' Cioni, and took his name from his master, the goldsmith Giuliano Verrocchi. As a teacher he occupies an important position from the fact that Leonardo da Vinci and Lorenzo di Credi worked for many years in his *bottéga* as pupils and assistants. Only one existing painting can be attributed by Vasari to Verrocchio, the celebrated "Baptism of Christ," originally painted for the monks of Vallombrosa, and now in the Uffizi Florence. The figures of Christ and the Baptist are executed with great vigour, but are rather hard and angular in style. The two angels are of a much more graceful cast; the face of one is of especial beauty, and Vasari asserts that this head was painted by the young Leonardo. Other pictures from Verrocchio's *bottéga* probably exist, as, for example, two in the National Gallery of London formerly attributed to Ant. Pollaiuolo—"Tobias and the Angel" (No. 781) and the very lovely "Madonna and Angels" (No. 296), both very brilliant and jewel-like in colour. This exquisite painting may possibly have been painted from Verrocchio's design by Lorenzo di Credi while he was under the immediate influence of his wonderful fellow-pupil, Da Vinci.

In examining Verrocchio's work as a sculptor we are on surer ground. One of Verrocchio's earliest sculptures is the bronze "David" in the Bargello, Florence (1469). In 1472 he completed the fine tomb of Giovanni and Piero de' Medici, in the first sacristy of San Lorenzo at Florence. This consists of a great porphyry sarcophagus enriched with magnificent acanthus foliage in bronze. Above it is a graceful open bronze grill, made like a network of cordage. The charming bronze putto with dolphin now in the court of the Palazzo Vecchio at Florence was intended for the villa Medici at Careggi. In 1474 Verrocchio began the monument to Cardinal Forteguerra in the cathedral of Pistoia. The kneeling figure of the cardinal was never completed, and now lies in a room of La Sapienza, but the whole design is shown in what is probably Verrocchio's original clay sketch now in the South Kensington. The actual execution of this work as designed by Verrocchio was entrusted to an assistant, the Florentine Lorenzetto. Somewhere between 1475 and 1480 is the terra-cotta relief of the Madonna and Child from S. Maria Nuova, now in the Bargello, a genuine standard work. In 1480 Verrocchio completed one of the reliefs of the magnificent silver altar-frontal of the Florentine baptistery, that representing the "Beheading of St. John." Verrocchio's other works in the precious metals are now lost, but Vasari records that he made many elaborate pieces of plate and jewelry, such as morses for copes, as well as a series of silver statues of the Apostles for the pope's chapel in the Vatican. Between 1478 and 1480 he was occupied in making the bronze group of the "Unbelief of St. Thomas," which still stands in one of the external niches of Or San Michele (Florence). He received 800 florins for these two figures, which are more remarkable for the excellence of their technique than for their sculpturesque beauty. The attitudes are rather rigid and the faces hard in expression. Verrocchio's most imposing work was the colossal bronze equestrian statue of the Venetian general Bartolommeo Colleoni, which stands in the piazza of SS. Giovanni e Paolo at Venice. Verrocchio received the order for this statue in 1485 but had only completed the model when he died in 1488. In spite of his request that the casting should be entrusted to his pupil Lorenzo di Credi, the work was given to Alessandro Leopardi who signed his name on the saddle girth. The statue was gilt and unveiled in 1496[1]. This is one of the noblest equestrian statues in the world. The horse is designed with wonderful nobility and spirit, and the pose of the great general is a marvel of sculpturesque ability. Most remarkable skill is shown by the way in which Verrocchio has exaggerated the strongly marked features of the general, so that nothing of its powerful effect is lost by the lofty position of the head. According to Vasari, Verrocchio was one of the first sculptors who made a practical use of casts from living and dead subjects. He is said also to have produced plastic works in terra-cotta, wood and in wax decorated with colour. As a sculptor his chief pupil was Francesco di Simone. Another pupil was Agnolo di Polo (Paolo), who worked chiefly in terra-cotta.

Verrocchio died in Venice in 1488, and was buried in the church of St. Ambrogio in Florence.

See also Hans Mackowsky, "Verrocchio" (1901), *Künster Monographien,* No. 52; M. Cruttwell, *Verrocchio* (1904); M. Reymond, *Verrocchio* (1906).

VERSAILLES, a town of northern France, capital of the department of Seine-et-Oise, 12 m. by road W.S.W. of Paris, with which it is connected by rail and tram. Pop. (1926) 68,575. Versailles owes its existence to the palace built by Louis XIV. It stands 460 ft. above the sea, and its fresh healthy air and nearness to the capital attract many residents. The three avenues of St. Cloud, Paris and Sceaux converge in the Place d'Armes. Between them stand the former stables of the palace, now occupied by the artillery and engineers. To the south lies the quarter of Satory, the oldest part of Versailles, with the cathedral of St. Louis, and to the north the new quarter, with the church of Notre-Dame.

The Palace.—To the west of the Place d'Armes a gilded iron

[1] *See* Gaye, *Cart. ined.* I., p. 367.

gate and a stone balustrade mark off the great court of the palace. In this court stand statues of Richelieu, Condé, Du Guesclin and other famous Frenchmen. At the highest point there is an equestrian statue in bronze of Louis XIV. To the right and left of this stretch the long wings of the palace, while behind extend the Cour Royale and beyond it the smaller Cour de Marbre, to the north, south and west of which rise the central buildings. To the north the Chapel Court and to the south the Princes Court, with vaulted passages leading to the gardens, separate the side from the central buildings. The palace chapel (1696–1710), the roof of which can be seen from afar rising above the rest of the building, was the last important work of J. Hardouin-Mansart.

The north wing contains galleries and halls of historical pictures and sculptures, and other great apartments, the most famous of which historically is the theatre built under Louis XV. where was held the banquet to the Gardes du Corps, the toasts at which provoked riots that drove Louis XVI. from Versailles. Here the National Assembly met from the 10th of March 1871 till the proclamation of the constitution in 1875, and the Senate from the 8th of March 1876 till the return of the two chambers to Paris in 1879. The central buildings include the former dauphin's apartments and many others on the ground floor and fine state-rooms on the first floor with the great "Galerie des Glaces" (1678) overlooking the park. The hall of Hercules was till 1710 the upper half of the old chapel famed for its associations with Bossuet, Massillon and Bourdaloue. The queen's apartments and the rooms of Louis XIV. are on this floor. The Oeil de Boeuf, named from its oval window, was the anteroom where the courtiers waited till the king rose. It leads to the bedroom in which Louis XIV. died, after using it from 1701, and which Louis XV. occupied from 1722 to 1738. In the south wing of the palace, on the ground-floor, is the Gallery of the Republic and the First Empire. In the south wing is also the room where the Chamber of Deputies met from 1876 till 1879, and where the Congress has since sat to revise the constitution voted at Versailles in 1875 and to elect the president of the republic. The first floor is almost entirely occupied by the Battle Gallery. In the window openings are the names of soldiers killed while fighting for France, with the names of the battles in which they fell, and there are more than eighty busts of princes, admirals, constables, marshals and celebrated warriors who met a similar death. Another room is given up to exhibits connected with the events of 1830 and the accession of Louis Philippe.

The Gardens.—The gardens of Versailles were planned by André Le Nôtre. The ground falls away on every side from a terrace adorned with ornamental basins, statues and bronze groups. Westwards from the palace extends a broad avenue, planted with large trees, and having along its centre the grass of the "Tapis Vert"; it is continued by the Grand Canal, 200 ft. wide and 1 m. long. On the south of the terrace two splendid staircases lead past the Orangery to the Swiss Lake, beyond which is the wood of Satory. On the north an avenue, with twenty-two groups of three children, each group holding a marble basin from which a jet of water rises, slopes gently down to the Basin of Neptune, remarkable for its fine sculptures and abundant water. The Orangery (built in 1685 by Mansart) is the finest piece of architecture at Versailles; the central gallery is 508 ft. long and 42 wide, and each of the side galleries is 375 ft. long. There are 1,200 orange trees, one of which is said to date from 1421, and 300 other kinds of trees.

The alleys of the parks are ornamented with statues, vases and regularly cut yews, and bordered by hedges surrounding the shrubberies. The Grand Canal under Louis XIV. was covered with Venetian gondolas and other boats. Around the Tapis Vert are numerous groves, the most remarkable being the Ballroom or Rockery, with a waterfall; the Queen's Shrubbery, the scene of the intrigue of the diamond necklace; that of the Colonnade, the King's Shrubbery, the Grove of Apollo, and the basin of Enceladus.

Among the chief attractions of Versailles are the fountains and waterworks made by Louis XIV. in imitation of those he had seen at Fouquet's château of Vaux. Owing to the scarcity of water at Versailles, the works at Marly-le-Roi were constructed in order to bring water from the Seine; but part of the supply thus obtained was diverted to the newly erected château of Marly. Vast sums of money were spent and many lives lost in an attempt to bring water from the Eure, but the work was stopped by the war of 1688. At last the waters of the plateau between Versailles and Rambouillet were collected and led by channels (total length 98 m.) to the gardens, the soil of which covers innumerable pipes, vaults and aqueducts.

The Trianons.—Beyond the present park, but within that of Louis XIV., are the two Trianons. The Grand Trianon was originally erected as a retreat for Louis XIV. in 1670, but in 1687 Mansart built a new palace on its site. Louis XV., after establishing a botanic garden, made Gabriel build in 1766 the small pavilion of the Petit Trianon. It was a favourite residence of Marie Antoinette, who had a garden laid out in the English style, with rustic villas in which the ladies of the court led a mimic peasant-life. The Grand Trianon contains a museum of state carriages, old harness, etc.

The Town.—The church of Notre-Dame, built by Mansart, and the cathedral of St. Louis, built by his grandson, are uninteresting. The celebrated tennis-court (Jeu de Paume) is now used as a museum. The palace of the prefecture, built during the Second Empire, was a residence of the president of the republic from 1871 to 1879. The military hospital formerly accommodated 2,000 people in the service of the palace. A school of horticulture was founded in 1874, attached to an excellent garden, near the Swiss Lake.

Versailles is the seat of a bishop, a prefect and a court of assizes, and has tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce and a branch of the Bank of France, and, among its educational establishments, lycées and training colleges for both sexes and a technical school. It is an important garrison town and has a school of military engineering and artillery. Distilling, boot and shoe making, and market-gardening are carried on.

History.—Louis XIII. often hunted in the woods of Versailles, and built a small pavilion at the corner of what is now the rue de la Pompe and the avenue of St. Cloud. In 1627 he entrusted Jacques Lemercier with the plan of a château. In 1661 Louis Levau made some additions which were further developed by him in 1668. In 1678 Mansart took over the work, the Galerie des Glaces, the chapel and the two wings being due to him. In 1682 Louis XIV. took up his residence in the château. Till his time the town was represented by a few houses to the south of the present Place d'Armes; but land was given to the lords of the court and new houses sprang up, chiefly in the north quarter. Under Louis XV. the parish of St. Louis was formed to the south for the increasing population, and new streets were built to the north on the meadows of Clagny. Under Louis XVI. the town extended to the east and received a municipality; in 1802 it gave its name to a bishopric. In 1783 the armistice preliminary to the treaty of peace between Great Britain and the United States was signed at Versailles. The states-general met here on the 5th of May 1789, and on the 20th of June took the solemn oath in the Tennis Court by which they bound themselves not to separate till they had given France a constitution. Napoleon neglected, and Louis XVIII. and Charles X. merely kept up, Versailles, but Louis Philippe made great alterations, some of which are being altered back to the original designs in a restoration recently undertaken, partly with the help of a large gift from the United States of America. In 1870 and 1871 the town was the headquarters of the German army besieging Paris, and in the Galerie des Glaces William I. of Prussia was crowned German emperor in 1871. After the peace Versailles was the seat of the French National Assembly while the commune was triumphant in Paris, and of the two chambers till 1879, being declared the official capital of France. After the World War the treaty between the Allied Powers and Germany was signed in the Galerie des Glaces.

See A. P. Gille, *Versailles et les deux Trianons*, with illustrations by M. Lambert (Tours, 1899, 1900); P. de Nolhac, *La Création de Versailles* (Versailles, 1901); J. E. Farmer, *Versailles and the Court under Louis XIV.* (New York, 1905).

VERSAILLES, TREATY OF, the treaty of peace that marked the close of the World War, signed by the representatives of the Allied Powers and of Germany on June 28, 1919, and brought into force by exchange of ratifications on Jan. 10, 1920. It was intended originally that it should be only one part of a general and inclusive treaty, comprising settlement with Austrians, Hungarians, Bulgars and Turks, as well as Germans. In such case it would have been strictly comparable to the Treaty of Vienna in 1815, which was, in fact, an "omnibus treaty." But the delays in dealing with these peoples, particularly Hungarians and Turks, not only separated the German treaty from the others, but caused it to be the first to be signed and the first to come into force, just as it was the first in importance.

I. NEGOTIATIONS BEFORE THE ARMISTICE

It is important, therefore, at the outset to understand the implications of the correspondence conducted between the German Government and President Wilson during Oct. and Nov. 1918, when the former was asking for peace. The governing document of the series is the reply of President Wilson to the German Government of Nov. 5, which embodied the result of the decisions of the principal Allied and Associated Governments as a whole (*i.e.*, France, Great Britain, Italy and the United States).

In that document they offered to make peace on the basis of President Wilson's speech on Jan. 8, 1918, which embodied the "Fourteen Points" (*q.v.;* excluding only point 2 relating to the freedom of the seas). In addition, they promised to make peace by "the principles of settlement embodied in his subsequent addresses," *i.e.*, speeches up to Nov. 5, 1918.

So we may say that the Allies offered to make peace on the general basis of President Wilson's speeches in 1918, *minus* his point about "freedom of the seas," and *plus* a definition of loss and damage. The Germans sent no reply to this offer in writing, but in fact accepted it by communicating with Marshal Foch and asking for an armistice. The course of the negotiations is related in the article PARIS, CONFERENCE OF, and all that can be done here is to indicate the character of the treaty itself and its apparent meaning as deduced from its clauses. It is at once the largest and the most complicated of modern treaties, and the best way to analyse it would seem to be to take its 15 parts separately.

II. ANALYSIS OF THE TREATY

Part I. The Covenant.—Part I. deals with the Covenant of the League of Nations (*see* COVENANT). It may be here remarked that the Covenant unites all its members in a league guaranteeing their territorial independence and integrity. The entrance of Germany into the League was deprecated at the time by some of the Allies and only became a certainty after the signature of the agreements of Locarno on Dec. 1, 1925, and their ratification in 1926. The most important powers granted to the League are the supervision of mandated territories (art. 22), whereby the future government of the German colonies, after having been assigned to various mandatory Powers, is subject to supervision by the Permanent Mandates' Commission. This is appointed by the League, and it inspects the annual reports of the mandatory Powers on the territory committed to their charge.

Similarly, the racial and religious Minorities' Treaties have been placed under the guardianship of the League, but their supervision here, though real, is not so effective as over territories under the mandates. Ultimately the supervision of disarmament, as provided in the German treaty, is to fall into the hands of the League, and this has finally been accomplished by the dissolution of the inter-Allied naval and military commissions and their supersession by the League at the end of 1925. The international control of health and disease is provided for in article 25 and has been actually much extended since. Article 23 provides for international co-operation in labour questions (*see* below, Part XIII.).

The most binding obligation of the League is found in articles 12–16, by which members bind themselves not to go to war in disregard of its covenants until three months of arbitration or inquiry by the council have elapsed. It is provided under article 8 that the League shall formulate plans for reduction of national armaments, and it took the lead in the disarmament conference opened in 1926.

The actual machinery, through which the League functions, consists at the outset of a council of nine, of whom five must be France, Great Britain, Italy, Japan and the United States. As the latter declined to accede, five out of the original nine seats were left to be filled by smaller states, whose representatives are elected by the Assembly of the League. Germany has, since 1926, entered the League and occupied a permanent seat on the Council. The Assembly consists of representatives of all member states, and is an annual international Parliament. Two institutions connected with, but actually separated from the League are the Permanent Court of International Justice (provided for under art. 14 and actually functioning since 1921), and the International Labour Office and annual conference (art. 23–4). The League also, as will be described below, is the governor of two important pieces of territory, the Saar basin and the free city of Danzig.

Parts II. and III. Territorial Dispositions.—(*a*) *Western Frontiers.*—Germany lost territory in the south, north and east as a result of the War, whilst other arrangements tended to weaken her influence beyond her own borders. Belgium, for example, ceased by article 31 to be a neutralised state, and has since entered into a military alliance with France. She has also acquired by cession from Germany the frontier districts of Moresnet, Eupen and Malmedy (art. 32–4); Luxembourg similarly ceases to be a neutralised state (art. 40–1), and has since entered into an economic union with Belgium. By articles 42–4 the whole left bank of the Rhine and the right bank to the west of a line drawn 50km. to the east of the Rhine, has been demilitarised forever. Fortifications are to be dismantled there, and no permanent works for manoeuvre or mobilisation are to be permitted.

By articles 45–50 the Saar basin forms an area under the control of an international commission and of the League, and its coal-mines are ceded to France. At the end of 15 years a plebiscite will be taken, whereby the inhabitants will vote as to their preference (*a*) for the existing international régime, (*b*) for union with France, (*c*) for union with Germany. Finally, and most important of all, by articles 51–79, Alsace and Lorraine are ceded by Germany to France. The latter thus gains nearly 2,000,000 inhabitants, great strategic advantages and over three-fourths of the German-produced iron with other valuable minerals.

(*b*) *Northern Frontier.*—Toward the north Germany consented (art. 115) to demolish the fortifications of Heligoland and to demilitarise it, but she retains its territorial sovereignty. She has lost the northern part of Schleswig to Denmark. By articles 109–14 it was provided that there should be a plebiscite in two zones. Of these, the northern voted for incorporation with Denmark and the southern, or Flensburg, zone elected for Germany. Denmark thus received that plebiscite which Bismarck had promised her but which he never gave (Art. III., Treaty of Nikolsburg, July 26, 1866).

(*c*) *Eastern Frontier.*—By articles 87–93 it was provided that there should be a plebiscite in Upper Silesia. This has resulted (1921) in a decision in which the southern half of the area—including valuable mines—passed to Poland, the upper half returning to Germany. Two other such plebiscites were provided for in East Prussia in the Allenstein and Marienwerder districts respectively, both of which went in favour of Germany. By the boundaries as drawn, a large part of the Posen and Bromberg area goes to the New Polish Republic. In addition, a Polish corridor is run to the sea between East Prussia and Brandenburg ending in the free city of Danzig. The latter is administered by the League but its foreign relations are controlled by Poland. Finally, the city and hinterland of Memel, ceded to the Principal Allies in the treaty, was handed over to Lithuania in 1924. About 3,500,000 former inhabitants of Germany are ceded to Poland or Lithuania in the east, of which rather less than one-third are German. Altogether, the total number of inhabitants ceded to the various Powers under the German Treaty falls not far short of 6,000,000. And this loss is probably a good deal less serious than the economic injury suffered by Germany in the loss of most of her iron and other minerals.

Part IV. German Rights and Interests Outside Germany.—By articles 119–27, Germany ceded all her oversea colonies to the Principal Allied Powers. She thus lost in Africa the Cameroons (divided between France and the British empire as mandatories); Togoland (to Great Britain as mandatory); Southwest Africa (to the Union of South Africa as mandatory); East Africa (to Great Britain and to Belgium as mandatories). These territories included some 18,000 Germans and between 12,000,000 and 13,000,000 natives. In the Pacific she lost the Marshall Isles (ceded to Japan as mandatory); Samoa (to New Zealand as mandatory); New Guinea (to Australia as mandatory); Nauru Island (to the British empire as mandatory). She also renounced outright to Japan (art. 156–8) the peninsula of Shantung, a province Japan returned to China in 1921. In addition to all these cessions of territory, Germany lost all her state property, movable and immovable, in her colonies. She was further obliged to cancel all her valuable treaty rights, capitulations and concessions with countries like China, Liberia, Siam, Egypt and Morocco. An absolutely clean sweep was made of her transmarine possessions, properties, powers and rights. By article 438 even the property and stations of German missionaries are to be handed over to trustees, and the individual missionaries controlled or expelled from the mandated territories, at the will of the mandatory. The course of time will show how far the general disabilities inflicted on German oversea undertakings will cripple the transmarine state enterprise of Germany in future, and hamper her private traders and steamship lines, as well as her missionaries.

Part V. Military, Naval and Air Clauses.—The aim of these clauses was similar in all cases, to destroy the existing German fortifications and the *matériel* of war, and to maintain Germany permanently in an absolutely weak and crippled condition, so far as armaments went. The maximum of the German army in future was to be 100,000 men, with stores of ammunition, guns, etc., in strict proportion. Beyond this figure all existing munitions, etc., were to be surrendered and destroyed and munition manufacture henceforth restricted. Germany consented to abolish conscription and to adopt a system of long-period voluntary enlistment of at least 12 years for the men, and of 25 for the officers. Military training outside the army was forbidden and the existence of a large general staff prohibited.

The naval clauses were almost equally drastic, and the German fleet was henceforth restricted to six battleships of the "Deutschland" type, six light cruisers, 12 destroyers, 12 torpedo boats (art. 181), in short, to a flotilla for coast defence, with the important proviso that submarines were absolutely forbidden. No new ships above 10,000 tons are to be built for replacement purposes. A voluntary long-period recruitment for the navy, on the lines of that of the army, was provided. A complete demolition of naval works and fortifications within 50km. of the coast was insisted on. The air clauses (art. 198–202) were the most drastic of all, for they absolutely prohibited naval or military air forces, and arranged for the total destruction of all military or naval air *matériel*. Inter-Allied commissions of control were provided for all these arms of the service, and their work was finally concluded in 1925. But the German armaments are still subject to supervision and inspection by the League.

Part VI. Prisoners of War and Graves.—This section is common to all the treaties and provides for the return of prisoners of war and for the upkeep and maintenance of graves. It calls for no special remark.

Part VII. Penalties.—This is the most disputable of all parts of the German treaty, as it is the only one that has remained wholly a dead letter. It provides (art. 227) for the trial of William II., "formerly German Emperor, for a supreme offence against international morality and the sanctity of treaties." An international tribunal of five, with one member nominated by each of the Principal Allies, was to try this high-placed offender. The statement of the procedure to be adopted, and of the punishment to be inflicted, was judiciously vague. The project never came to anything because the Netherlands Government, in whose territory the ex-Kaiser had taken refuge, refused to surrender him in accordance with the Allied request.

Articles 228–30 provided for the punishment before military tribunals of the allies of Germans "accused of having committed acts in violation of the laws and customs of war." Eventually a list of over 100 such criminals was drawn up, and their extradition demanded from Germany. Finally, about a dozen of them were tried in Germany itself by Germans and, though only a few were convicted, the Allied Governments decided to drop the matter, for extradition was impossible without fighting. In 1925 Field-Marshal Hindenburg, himself a "war criminal," was elected President of the Republic without any formal Allied protest.

Part VIII. Reparation.—This is among the most celebrated and important of the sections of the treaty, and it was affected more than any other by outside and popular influences. The payments demanded were called "reparation" rather than indemnity. Article 232 defined (in connection with an annex) the categories of loss and damage under which Germany was liable. Among these was included pensions to civilians. This seems clearly contrary to the definition given in the memo. of Nov. 5, 1918, which has been quoted above. It would appear from the doubtful manner in which this question is handled in the covering letter and *reply* of June 16 that the Allies themselves were uneasy upon this point.

The remainder of Part VIII. is concerned with the ways and means of paying reparation, and a body, known as the Reparation Commission, was set up with very extensive powers. It appears that D. Lloyd George intended these powers to be used for the purpose of greatly reducing the ultimate liabilities of Germany, but the absence of the United States from the commission and the French influence upon it, together with English popular opinion, defeated this idea. The later course of reparation cannot detain us here, but the original proposals were greatly modified in execution. Mr. Keynes estimated at the time that about £2,000,000,000 was all that could be got out of Germany, and it is pretty certain that £3,000,000,000, or at most £4,000,000,000, represented the utmost they could have paid. The institution of the Dawes Scheme in 1924 put an end to the original reparation clauses.

The payments in kind provided for in article 236, and in various annexes, were based on sounder ground. They included, among other things, "the ton for ton, and class for class" replacement of Allied merchant shipping by German vessels. Great Britain obtained most under this head; France most by deliveries of coal and coal derivatives; Belgium by livestock.

Part IX. The Financial Clauses.—This section is largely technical, dealing with order of priority, with the meeting of special debts from special assets, currency questions, etc. It is closely connected with the "Reparation Chapter."

Part X. Economic Clauses.—The first section of this consists of articles 264–75, which deals with commercial relations, shipping and unfair competition, commercial treaties, etc. Much was attempted at the conference in the way of promoting internationalisation of rivers and canals and transport. It was even proposed to make raw materials free of tariffs throughout the world. But in the end the only practical gain was that the Allied Powers secured a "most favoured nation treatment" from Germany for five years, and adjusted various commercial treaties for this purpose.

Sections III.–VIII. (articles 296–311) provide for the regulation of enemy property, debts, contracts, etc. In the liquidation of German property in foreign countries the principle was adopted of giving the Allies power to confiscate the private property of German individuals in an allied country, and of crediting the sums obtained to the amount paid as reparation by the German National Government. In other words, the private property of German individuals held anywhere abroad was as liable to confiscation for reparation purposes, as if it had been German state property confiscated in a ceded colony. The German *Observations* to the Allies seem to admit that German private property held abroad could not be expected to escape altogether.

The Allies, in their *Reply* of June 16, pointed out that they had had, as a result of the War, to take over foreign investments from their nationals, thus infringing on their private rights. They added: "the time has arrived when Germany must do what she has forced her opponents to do." It is quite true that, though private property was invariably respected in former wars, the ad-

vance of socialistic ideas and the conditions of modern warfare cause difficulty in applying strictly the doctrines of total immunity of private property.

Part XI. Aerial Navigation.—This merely arranges for full liberty of passage and facilities for Allied airships flying over Germany up till Jan. 1, 1923.

Part XII. Ports, Waterways and Railways.—This is an important section, though a highly technical one. The aim was to secure international control over rivers which flowed through more than one country. This was a very extraordinary development from the doctrine laid down as to international rivers at Vienna in 1815. It was, however, affected by the desire to provide access to the sea for countries like Switzerland and Czechoslovakia. These were land-locked, though they are the source of rivers which end in the sea. International commissions were set up to control the Rhine, Oder, Elbe, Niemen and Danube. The result is that Germany is in a minority in the control of three rivers regarded as typically German, the Rhine, Oder and Elbe. The Kiel canal is in effect internationalised to give freedom of access to all vessels of whatever country in peace and in war but, subject to this condition, is under German administration. Access to the sea is secured by providing free zones for Czechoslovakia in the harbours of Hamburg and Stettin. As regards international transport by rail, the clauses were mostly of a temporary nature; and were subsequently more defined by an international transport conference held at Barcelona in 1921 under the auspices of the League.

Part XIII. Labour.—This section marks the beginning of an attempt to build up an elaborate fabric of international Labour machinery, to provide for periodic international discussion, and to arrange for the representation both of employers and of working men. Three Labour representatives took part in its construction, Samuel Gompers of the United States, George N. Barnes of Great Britain, and Albert Thomas of France, the last-named becoming the permanent head of the International Labour Office. This is established at Geneva side by side, but not identical, with the League Secretariat. It is, in fact, the instrument set up to carry out article 23*a* of the Covenant by which the members undertook "to endeavour to secure and maintain fair and humane conditions for men, women and children, both in their own countries and in all countries to which their commercial and industrial relations extend." Though an integral part of the League, its character and organs are autonomous, which is not the case with the machinery set up to deal with health and transit questions. In the allocation of its finance the League has control, but not over the organs, of international Labour. The Labour Office is controlled by the governing body of 24 persons, of whom 12 represent Governments; six are elected by employers' delegates to the conference and six by workers' delegates to the conference.

The general conference, or Labour parliament, which has to meet once every year, consists of over 200 members, and is constituted as follows: Every member of the League is entitled to four representatives, of whom the state government nominates two, while a third is elected by the employers and a fourth by the workers of the state concerned. The conference has met annually, but has met with grave difficulties in the application of universal rules and standards. (*See* INTERNATIONAL LABOUR ORGANIZATION.)

Part XIV. Guarantees.—Provision was made in the military clauses (*see* above) for the demilitarisation of the left bank of the Rhine. But a military occupation of Allied troops is also provided for. By article 428 the whole of this area, together with bridgeheads across the Rhine, is to be occupied for 15 years from the coming into force of the treaty (Jan. 10, 1920). But it is provided in article 429 that there shall be a successive Allied evacuation of the three zones and bridgeheads into which the area is divided. That of Cologne was to be evacuated in five years, that of Coblenz in 10 and of Mainz in 15. Those evacuations are not, however, to take place unless Germany faithfully carries out the provisions of the treaty as a whole. The Cologne evacuation was delayed from Jan. to Dec. 1925 on this account.

But the meanings of articles 429 and 430 appears to be that the Allies are only permitted to continue occupation if German conduct proves unsatisfactory. There does not seem any justification under the treaty for the action taken by the Allies as a whole, including Great Britain, in 1921, when areas in Germany beyond the bridgeheads were occupied. Still less would there appear to be any justification for the occupation of the German district of the Ruhr by the French and Belgians in Jan. 1923. This was not approved of at the time by the British Government, and was subsequently declared by them to be in their opinion illegal in a note to the French Government (Aug. 1923). As a guarantee for the settlement of the eastern frontier of Germany, as fixed at the peace, article 433 abrogates the Brest-Litovsk treaties (*q.v.*) between Germany and Soviet Russia and binds all German troops to evacuate territory beyond their new frontier.

Part XV. Miscellaneous Provisions.—This consists of a number of miscellaneous and technical matters which were accidentally omitted elsewhere. In so far as they are of any importance they are mentioned in connection with their appropriate subject above.

III. SUMMARY

The German treaty appears, when its various items are assembled together, to have been crushing and severe to a high degree. This result was partly due to the fact that the separate parts of the treaty were worked out by the different committees, and its cumulative effect not recognized when they were assembled together. It is due, however, more particularly to the fact that popular pressure was very great both on President Wilson, Lloyd George and Clemenceau not to make a lenient peace.

At the beginning of June Lloyd George again showed a tendency to moderation, but now Wilson had made up his mind and all efforts were useless. Clemenceau was considered by some French organs not to have sufficiently supported the interests of France, and he could hardly have been more moderate, even had he so desired. The representatives of the British dominions were generally in favour of severity, with the conspicuous exceptions of Generals Botha and Smuts, who strongly urged moderation. The chief defects of the peace, the procedure against the Kaiser and the War criminals and the inclusion of pensions to civilians in reparation, must be considered concessions to popular feeling rather than due to the deliberate judgment of the peace negotiators. The first two have been abandoned and the last greatly modified. The territorial concessions were carefully considered and may, with some effort, be brought within the bounds of "the Fourteen Points" and of the Wilsonian principles. As regards permanent maintenance of the new frontiers, the British Government has guaranteed these in the west by the Locarno Treaty, but they are evidently not prepared to give any special guarantees for the existing eastern frontiers of Germany, though France has promised to support Poland and Czechoslovakia against Germany, if need arise.

The "guarantees" section of the Peace treaty was carried out by the evacuation of the Cologne area and by the tacit abandonment of policies like the invasion and occupation of the Ruhr. The Property section of the treaty has been, in great part, modified or abandoned. No great diplomatic instrument has ever been so speedily modified, revised or altered, whether by tacit consent or by deliberate design. Two parts of the treaty alone have expanded and developed, the institutions set up by the international Labour organization and by the League. (H. W. V. T.)

Texts. The Treaty of Peace, ed. with notes by H. W. V. Temperley, with *Introduction* by Lord R. Cecil (1920).

VERSE, the name given to an assemblage of words so placed together as to produce a metrical effect. The art of making, and the science of analysing, such verses is known as versification. According to Max Müller, there is an analogy between *versus* and the Sanskrit term, *vritta,* which is the name given by the ancient grammarians of India to the rule determining the value of the quantity in Vedic poetry. A verse is a series of rhythmical syllables, divided by pauses, and destined to occupy a single line.

Greek Metre.—The chief principle in ancient verse was quantity, *i.e.,* the amount of time involved in expressing a syllable. Accordingly, the two basal types which lie at the foundation of classical metre are "longs" and "shorts." The convention was that a long syllable was equal to two short ones: accordingly there was a real truth in calling the succession of such "feet" metre, for the length, or weight, of the syllables forming them could be, and was, measured. In Greek verse, there might be an *ictus* (stress), which fell upon the long syllable, but it could only be a regulating element, and accent was always a secondary element in the construction of Greek metre. There are naturally only two movements, the quick and the slow. Thus we have the anapest (⏑⏑–) and the dactyl (–⏑⏑), which are equal, and differ only as regards the position of their parts. After these follow two feet which must be considered as in their essence non-metrical as it is only in combination with others that they can become metrical. These are the spondee (––) and the pyrrhic (⏑⏑). Of more essential character are the iambic (⏑–) and the trochee (–⏑). Besides these definite types, the ingenuity of formalists has invented an almost infinite number of other "feet." It is, perhaps, necessary to mention some of the principal of these, although they are, in the majority of cases, purely arbitrary. In the rapid measures we find the tribrach (⏑⏑⏑), the molossus (–––), the amphibrach (⏑–⏑), the amphimacer (–⏑–), the bacchius (⏑––) and the antibacchius (––⏑). There is a foot of four syllables, the choriamb (–⏑⏑–) and one of five, the dochmiac (⏑––⏑–).

Of the metres of the ancients, by far the most often employed, and no doubt the oldest, was the dactylic hexameter, a combination of six feet, five successive dactyls interchangeable except in the fifth foot with spondees and a spondee or trochee:—

This was known to the ancients as "epic" verse, in contrast to the various lyrical measures. The poetry of Homer is the typical example of the use of the epic hexameter, and the character of the Homeric saga led to the fashion by which the dactylic hexameter, whatever its subject, was styled "heroic metre." The earliest epics, doubtless, were chanted to the accompaniment of a stringed instrument, marking the pulsation of the verse ἔπη.

We pass, by a natural transition, to the pentameter, which was used with the hexameter, to produce the effect which was early called elegiac, and its form shows the appropriateness of this custom:—

"Cynthia | prima fu- | it, || Cynthia | finis e- | rit."

A hexameter, full of energy and exaltation, followed by a descending and melancholy pentameter, had an immediate tendency to take a complete form, and this is the origin of the stanza. Such a distich was called an elegy, ἐλεγεῖον, as specially suitable to an ἔλεγος or lamentation. It is difficult to say with certainty whether the distich so composed was essential as an accompaniment to flute-music in the earliest times, or how soon there came to be written purely literary elegies towards which the melody stood in a secondary or ornamental relation.

Iambic metre was, next to the dactylic hexameter, the form of verse most frequently employed by the poets of Greek antiquity. It was not far removed from prose; it gave a writer opportunity for expressing popular thoughts in a manner which simple men could appreciate, being close to their own unsophisticated speech. In particular, it presented itself as a heaven-made instrument for the talent of Euripides.

It was not, however, until the invention of the lyric proper, whether individual to the poet, or choral, that the full richness of possible rhythms became obvious to the Greeks. The lyric inspiration came originally from the island of Lesbos, and it passed down through the Asiatic archipelago before it reached the mainland of Greece. The Lesbians cultivated an ode-poetry, the enchanting beauty of which can still be realized in measure from what remains to us of the writings of Sappho and Alcaeus. There is a stanza known as the Sapphic and another known as the Alcaic.

The name of Stesichorus of Himera points to the belief of antiquity that he was the earliest poet who gave form to the choral song; he must have been called the "choir-setter" because he arranged and wrote for choirs semi-epic verse of a new kind, "made up of halves of the epic hexameter, interspersed with short variations—epitrites, anapaests or mere syncopae—just enough to break the dactylic swing, to make the verse lyrical" (Gilbert Murray). But it appears to be to Arion that the artistic form of the dithyramb is due. Pindar gathered the various inventions together, and exercised his genius upon them all.

After the happy event of the Persian War, Athens became the centre of literary activity in Greece, and here the great school of drama developed itself, using for its vehicle, in dialogue, monologue and chorus, nearly all the metres which earlier ages and distant provinces had invented. The verse-form which the dramatists preferred to use was almost exclusively the iambic trimeter, a form which adapted itself equally well to tragedy and to comedy. Aeschylus employed for his choruses a great number of lyric measures, which Sophocles and Euripides reduced and regulated. With the age of the dramatists the creative power of the Greeks in versification came to an end, and the revival of poetic enthusiasm in the Alexandrian age brought with it no talent for fresh metrical inventions.

Latin Metre.—Very little is known about the verse-forms of the original inhabitants of Italy, before the introduction of Greek influences. The earliest use of poetry as a national art in Italy is to be judged by inscriptions in what is called the Saturnian metre. The introduction of Greek dramatic metre marks the start of regular poetry among the Latins, which was due, not to men of Roman birth, but to poets of Greek extraction or inhabiting the Greek-speaking provinces of Italy. These writers, bearing the stamp of a widely recognized cultivation, threw the old national verse back into oblivion. Latin verse, then, began in a free but loyal modification of the principles of Greek verse. Plautus was particularly ambitious and skilful in this work, and, aided by a native genius for metre, he laid down the basis of Latin dramatic versification. Terence was a feebler and at the same time a more timid metrist. In satire, the iambic and trochaic measures were carefully adapted by Ennius and Lucilius. The dactylic hexameter followed, and Ennius, in all matters of verse a daring innovator, directly imitated in his *Annales* the epic measure of the Greeks. To him also is attributed the introduction of the elegiac distich. The dactylic hexameter was forthwith adopted as the leading metre of the Roman poets, and the basis upon which all future versification was to be erected was firmly laid down before the death of Ennius in 169 B.C. Lucilius followed, but perhaps with some tendency to retrogression, for the Latin critics seem to have looked upon his metre as wanting both in melody and elasticity. Lucretius, on the other hand, made a further advance on the labours of Ennius, in his study of the hexameter. Lest, however, this great form of verse should take too exclusive a place in the imagination of the Romans, a younger generation began to imitate the lyrical measures of the Greeks with remarkable success. These poets left the rigid school of Ennius, and sought to emulate the Alexandrians of their own age: we see the result in the lyric measures used so gracefully and with such brilliant ease by Catullus. The versification of the Romans reached its highest point of polish in the Augustan age, in the writings of Tibullus, Propertius, Virgil and Ovid. Horace in his odes and epodes was not content with the soft Alexandrian models, but aimed at achieving more vigorous effects by an imitation of the older Greek models.

Modern Versification.—The main distinction between

classical and modern versification consists in the substitution of stress for quantity on the basis of metre, corresponding to a change of enunciation which set in in the late classical period. A syllable, in modern verse, is heavy or light, according as it is stressed or unstressed.

The prosodies of Provence, France, Italy and Spain were derived from popular accentual Latin verse by a slow and intangible transition. Versification, deprived of all the regulated principles of rhythmical art, received in return the ornament of rhyme, without which the weak rhythm itself would practically have disappeared. A new species of rhythm, depending on the varieties of mood, was introduced, and stanzaic forms of great elaboration and beauty were invented. The normal line is of ten or eight syllables: the alexandrine of 12 appears later. In Provençal and early French the position of the caesura in each line was fixed by strict rules; in Italian these were relaxed. Dante, in the *De Vulgari Eloquentia,* gives very minute, although somewhat obscure, accounts of the essence and invention of stanzaic form (*cobla* in Provençal), in which the Romance poetries excelled from the first. The stanza was a group of lines formed on a regular and recurrent arrangement of rhymes. It was natural that the poets of Provence should carry to an extreme the invention of stanzaic forms, for their language was extravagantly rich in rhymes. They invented complicated poetic structures of stanza within stanza, and the *canzo* as written by the great troubadours is a marvel of ingenuity such as could scarcely be repeated in any other language.

In French poetry, successive masters corrected the national versification and drew closer round it the network of rules and principles. Immutable rules were laid down by Malherbe, and by Boileau in his *Art Poétique* (1674), and for more than a century they were implicitly followed by all writers of verse. It was the genius of Victor Hugo which first enfranchised the prosody of France, not by rebelling against the rules, but by widening their scope in all directions, and by asserting that, in spite of its limitations, French verse was a living thing.

In very early times the inhabitants of the Germanic countries developed a prosodical system which owed nothing whatever to classical sources. The finest examples of this Teutonic verse are found in Icelandic and in Anglo-Saxon. The line consisted of two sections, each containing two strongly stressed syllables, and of these four syllables three (or at least two) were alliterated. In all ancient Teutonic verse three severe and consistent rules can be observed, viz., that the section, the strong accentuation, and above all the alliteration must be preserved. We find this to be the case in High and Low German, Icelandic, Anglo-Saxon, and in the revived alliterative English poetry of the 14th century, such as "Piers Plowman."

English Metre.—The first writer in whom there has been discovered a distinct rebellion against the methods of Anglo-Saxon versification is St. Godric, who died in 1170. Only three brief fragments of his poetry have been preserved, but there is no doubt that they show, for the first time, a regular composition in feet. A quotation will show the value of St. Godric's invention:—

"Saintë | Nicholaes, | Godes | druth,
Tymbre us | fairë | sconë | hus,
At thy | burth, | at thy | bare,
Saintë | Nicholaes, | bring uswel thare."

From this difficult stanza down to the metres of modern English the transition seems gradual and direct, while the tradition of Anglo-Saxon alliterative prosody is abruptly broken. There is still more definition of feet in the *Poema Morale* (*c.* 1200). The *Ormulum,* which belongs to the early part of the 13th century, is monotonously regular. A further advance was made about 50 years later in *Genesis and Exodus,* of which Saintsbury has said that "it contains more of the kernel of English prosody, properly so called, than any [other] single poem before Spenser." The phenomenon which we meet with in all these earliest attempts at purely English verse is the unconscious determination of writers, who had no views about prosody, to work the varying stresses of English with the kind of regularity which they heard in French and Latin.

Between 1210 and 1340 not one English poem of importance is known to have been written in the old alliterative measure of the Anglo-Saxons. But at the latter date there set in a singular reaction in favour of alliteration, a movement which culminated, after producing some beautiful romances, in the satires of Langland. Those writers, and they were many, who preserved foot-scansion and rhyme, during this alliterative reaction, became ever closer students of contemporary French verse, and in the favourite octosyllabic metre "the uncompromising adoption of the French, or syllabically uniform, system is the first thing noticeable" (Saintsbury). This tendency of Middle English metre culminates in the work of John Gower, which is singularly polished in its rhyming octosyllabics, although unquestionably nerveless still, and inelastic.

It is, however, to Chaucer that we turn for far greater contributions to English verse. He it was who first, with full consciousness of power as an artist, adopted the use of elaborate stanzas, always in following of the French; he it was who first gained freedom of sound by a variation of pause, and by an alternation of trochaic and iambic movement. It is the lack of these arts which keeps Gower and his predecessors so stiff. In particular Chaucer, in his first period, invented rime-royal, a stanzaic form (in seven decasyllabic lines, rhymed *a b a b b c c*), peculiarly English in character, which was dominant in our literature for more than 200 years; it was used in the long romance of *Troilus and Creseide,* where English metre for the first time displays its beauty to the full. It seems to have been originally called riding-rhyme, the name by which Gascoigne describes it (1575).

Throughout the 15th and early 16th centuries there began to arise the popular ballads. The introduction of the loose, elastic ballad-quatrain, with its melodious tendency to refrain, was a matter of great importance in the metamorphosis of British verse. The degenerate forms employed by the English 15th-century poets in attempting more regular prosody were in some measure corrected by the greater exactitude of the Scotch writers, particularly of Dunbar, who was by far the most accomplished metrist between Chaucer and Spenser. But Wyatt (1503–42) was the great pioneer. He introduced, from France and Italy, the prosodical principles of the Renaissance—order and coherency, concentration and definition of sound—and that although his own powers in metre were far from being highly developed. He and his more gifted disciple Surrey introduced into English verse the sonnet (not of the pure Italian type, but as a quatorzain with a final couplet) as well as other short lyric forms. To Surrey, moreover, we owe the introduction from Italian of blank verse.

With the heroic couplet, with blank verse, and with a variety of short lyric stanzaic measures, the equipment of British verse might now be said to be complete. For the moment, however, towards the middle of the 16th century, all these excellent metres seemed to be abandoned in favour of an awkward couplet of 14 feet. It was to break up this nerveless measure that the remarkable reforms of the close of the century were made, and the discoveries of Wyatt and Surrey were brought, long after their deaths, into general practice. In drama, the doggerel of an earlier age retired before a blank verse, which was at first entirely pedestrian and mechanical, but struck out variety and music in the hands of Marlowe and Shakespeare. But the central magician was Spenser, in whom there arose a master of pure verse whose range and skill were greater than those of any previous writer of English, and before whom Chaucer himself must withdraw. His great work was that of solidification and emancipation, but he also created a noble form which bears his name, that Spenserian stanza of nine lines closing with an alexandrine, which lends itself in the hands of great poets, and great poets only, to magnificent narrative effects.

It was at this moment that a final attempt was made to disestablish the whole scheme of English metre, and to substitute for it unrhymed classic measures. In the year 1579 this heresy was powerful at Cambridge, and a vigorous attempt was made to include Spenser himself among its votaries. It failed, and with this failure it may be said that all the essential questions connected with English poetry were settled. (E. G.; X.)

VERTEBRATA, one of the main subdivisions or phyla of the animal kingdom, including such familiar animal types as mammals (including man), birds, reptiles, amphibians, fish, along with such less familiar types as lampreys and hagfish (Cyclostomata, *q.v.*). The name is not precisely equivalent to Chordata: the latter name is used to include in addition to typical vertebrates, the Tunicata (*q.v.*), which are universally accepted as degenerate relations of the vertebrates, and also certain other types such as *Balanoglossus* (*q.v.*) and *Pterobranchia* (*q.v.*) whose genetic affinity with the Vertebrata is more doubtful. The phylum is marked off from all others by a plan of bodily structure peculiar to itself, including (1) an axial supporting skeleton traversing the body longitudinally in the mesial plane, (2) a muscular system consisting primarily of longitudinal muscle-fibres situated to right and left of the axial skeleton, and (3) the concentration of the central nervous system and the main blood-vessels in longitudinal trunks in the region of the mesial plane, the nervous system dorsal to, and the great vessels, as well as the other main organs of the body, ventral to the axial skeleton.

The axial skeleton in its primitive condition, as seen in one of the lower types or as a temporary phase in the embryos of the higher, consists of a stiff rod, the notochord, cellular in nature, its stiffness due to the distension of its constituent cells by fluid secreted in their interior. In the more typical vertebrates this continuous notochord gives place to a jointed chain of rigid vertebrae, giving increased flexibility combined with more efficient support.

The muscular system shows the peculiarity that the longitudinal fibres composing it are limited in length to that of a single mesoderm segment, so that the system consists of a series of paired blocks or myotomes, each composed of a mass of longitudinal fibres. The physiological significance of this arrangement is that contraction of the myotomes in turn from the head end backwards produces waves of lateral flexure which, driven back along the body and acting against the resistance of the external medium, bring about forward movement of the body as a whole. The construction of the body for such eel-like movement is perhaps the most fundamental feature of vertebrates and it is in accordance with it that the important longitudinal conducting organs of the body, such as central nervous system and main blood vessels, whose functions would be seriously interfered with by compression, are situated mesially.

The adaptation of the vertebrate to forward movement in a definite direction carries with it correlated modifications in structure of the terminal portions of the body. In front, special paired sense-organs are developed for the reception of impressions from the outer world—chemical (olfactory organs), or optical (eyes; peculiar in that they are myelonic, *i.e.*, developed out of the side of the tubular nerve cord) or mechanical (otocyst). There follows in the neighbourhood of these sense-organs a concentration of the special nerve-centres, accommodated by expansion of the central nervous system to form the brain. The mouth too is situated near the anterior end, and the alimentary canal (pharynx) immediately behind the buccal cavity shows characteristic perforation of its side-walls by a series of visceral clefts whose vascular walls form respiratory organs (gills). In compensation for the resulting weakening of the pharyngeal wall, the mass of tissue between adjacent clefts ("visceral arch") develops in its interior a skeletal hoop of cartilage or bone. These skeletal arches become modified in detail in various ways and, in the case of the anterior one, these modifications form the jaws that support the margins of the mouth-opening. The mouth-opening of the primitive vertebrate appears to have been situated on the ventral side of the head under a forwardly projecting, overhanging lobe, a position which it still retains in the shark-like fishes to-day. The anal opening similarly was possibly situated close to the hinder end of the body, but there is a characteristic tendency for it to become displaced forwards along the ventral side of the body, reaching its maximum in some of the teleostean fishes, where the anus is jugular.

The Vertebrata in general possess two pairs of appendages or limbs—pectoral and pelvic—both liable to great modifications in adaptation to particular habits. The earliest known vertebrates (early ostracoderms) possessed no true limbs, and this limblessness is shared by the cyclostomes. These facts have led many authorities to believe that the vertebrates were originally without limbs. But it must be remembered that with the development of a specially elongated form of body, the limbs tend to disappear (many reptiles such as serpents and certain lizards: and the Apoda amongst Amphibia) and this disappearance may be so complete as to leave no vestige even in the embryo.

The advancement of knowledge entails greater caution in accepting dogmatic conclusions as to the evolutionary history of the Vertebrata than was customary a few years ago. It is clear that the normal jawed vertebrates (Gnathostomata) of to-day fall naturally into two distinct sets: (1) Fish, constructed for swimming and (2) Tetrapods adapted for movement upon a solid substratum.

The former fall into a number of subsidiary groups: Elasmobranchii with Holocephali; Crossopterygii; Actinopterygii, including a few more archaic types (sturgeons, gar-pike, bowfins) together with the vast assemblage of modern bony fishes or Teleostei; and the Dipnoi or lungfish. Each of these groups represents a terminal twig of the evolutionary tree.

Existing tetrapods also fall into well-marked groups—amphibians, reptiles, birds and mammals. Here again evolutionary conclusions must be limited to broad general principles. On the whole the amphibians are the most archaic while the birds are the most highly evolved. The mammals hold their dominating position not in virtue of high organization in general but rather in virtue of their special development of brain.

In earlier days it was also customary to debate the claims of various groups of invertebrates to represent the ancestral type from which the vertebrates originated. Here again the advance of knowledge has indicated the need for greater caution.

In the opinion of the writer of this article our present-day knowledge of the facts of vertebrate morphology forbids our going farther than to suggest that amongst the post-coelenterate phases of vertebrate evolution was a stage having "features in common" with annelids. It should be mentioned however that at the present time many zoologists are inclined to regard the echinoderms, and still more *Balanoglossus* and its allies, as being related to the ancestral stock of the vertebrates. (*See* FISHES, SELACHIANS, AMPHIBIA, REPTILES, BIRD, ORNITHOLOGY, MAMMALIA, etc.) (J. G. K.)

VERTEBRATE EMBRYOLOGY. The science of embryology (*q.v.*) had its first beginnings in the study of the Vertebrata (*q.v.*), the group that includes those forms of life whose eggs and breeding habits naturally first attracted attention, and even to-day the mass of known embryological detail relating to vertebrates far exceeds that relating to any other phylum. Further there is no phylum of the animal kingdom which shows in so varying degrees the modifying influence of such factors as amount of yolk in the egg, external environmental conditions, etc.

The Zygote.—The vertebrate, like most animals, begins its existence as a single cell, the *zygote* or fertilized egg, formed by the fusion of two gametes, derived one from each parent. The zygote possesses in itself all the specific peculiarities of the complete individual of its species. To human observation, however, the zygotes of different animals do not exhibit any of the peculiarities differentiating the adults. Such peculiarities as they do pre-

sent are in such comparatively trivial characters as size, shape, colour. Otherwise each zygote is to all appearance simply a typical cell with cytoplasm and nucleus. The superficial differences have to do mainly with adaptive features enabling the young individual to remain for a more or less prolonged period within the shelter of an egg-shell. This is rendered possible in the first instance by the zygote possessing in its cytoplasm a store of *yolk*—highly concentrated food-material—which provides it with subsistence. The greater the amount of this yolk-capital stored away in the zygote, the greater its size: there is a rough proportion between size of egg and quantity of yolk. Thus in *Amphioxus* the zygote has a very minute trace of yolk in its cytoplasm and its diameter is about 0·1 mm.: in the extinct bird *Aepyornis* of Madagascar, judging from the size of the shell, the zygote may have been as much as 160 mm. in diameter.

In the Mammalia of the most ancient type (Monotremata, *q.v.*), which still lay their eggs, these are large and richly yolked (*Echidna* 3·5 mm., *Ornithorhynchus* 2·5 mm.), and the young pass through the early development within the egg-shell.

In the ordinary modern mammal, on the other hand, the egg is not laid in the ordinary sense. The zygote is retained within the uterus and there proceeds with its development, absorbing such nourishment as it requires from the mother. The store of yolk, no longer necessary, has disappeared and the zygote has reverted to the small size of from 0·1 mm. to 0·3 mm. in diameter.

Peculiarities of colour are often due to the yolk, *e.g.*, orange-yellow in the case of birds, salmon-pink in *Lepidosiren*, green in *Amia*. Yolk is not however the only cause of coloration of the vertebrate zygote. Particularly among the Amphibia, where the egg develops under conditions of exposure to the harmful influence of daylight, the superficial layer of protoplasm shows the peculiar "upset" of its metabolism which results in dark brown or black melanin pigment, thus producing a protective, light-proof shelter over the deeper protoplasm. This is well seen in the black eggs of the ordinary frogs and toads.

It will be borne in mind that the technical term zygote expresses the unicellular stage arising from the fusion of the two gametes. As the male gamete or spermatozoon is of quite insignificant bulk as compared with the macrogamete (unfertilized egg), the obvious features described for the zygote—such as size and colour—have been taken over by it from the macrogamete. The provision of a supply of capital in the form of yolk upon which the individual can subsist during its early stages is correlated with the fact that during these early stages it lives within the shelter of more or less elaborate protective envelopes. Such are seen in simple form in an ordinary frog, where the egg during its passage down the oviduct is coated with a thin layer of secretion possessing the quality of swelling enormously in bulk when placed in contact with water, the result being the familiar frog-spawn, where each egg lies in the centre of a sphere of clear jelly composed of the greatly swollen layer of oviducal secretion.

The zygote is moored in the centre of the albumen by the axial strand of albumen of a denser, tougher consistency—the "chalaza." If the egg-shell is rolled over, the chalaza, while keeping the zygote at its proper distance from the poles of the shell, allows it to rotate about the long axis of the shell, itself twisting in the process. Consequently the apical pole of the zygote, with its germinal disc less heavily weighted by yolk, always keeps uppermost next the warm body of the incubating hen even when the shell is turned over.

Segmentation.—The first visible phase in development is the *segmentation* or *cleavage*, by which the unicellular zygote resolves itself into the mass of cells constituting the embryo. As in other cases (*see* EMBRYOLOGY), the character of the segmentation is greatly influenced by the relative amount of the yolk and still more by its distribution within the zygote. Thus in the ordinary mammal, where there is practically no yolk, the zygote simply divides into two equal blastomeres, each of these again into two equal daughter-cells and so on.

Gastrulation.—In the Vertebrata, as in so many other cases, the process of segmentation, resulting in a blastula or hollow sphere of cells, is succeeded by *gastrulation*, resulting in the formation of a more or less cup-shaped gastrula, composed of two layers of cells—ectoderm and endoderm—surrounding a cavity, the archenteron, with a wide opening to the exterior the primitive mouth or protostoma.

Gastrulation is seen amongst vertebrates in its most primitive form in *Amphioxus* where the abapical hemisphere of the blastula, marked by its larger cells, becomes first flattened and then involuted (invaginated) into the interior of the apical hemisphere. The widely open protostoma becomes gradually narrowed through one lip of the gastrula, shown by later development to be the anterior lip, growing actively backwards so as gradually to cover in the cavity or archenteron, except at its hind-end where the persisting part of the protostoma remains as a small pore—the blastopore. The study of subsequent stages shows that the portion of the embryo formed by this process of backgrowth, *i.e.*, the roof of the archenteron, becomes the dorsal side of the embryo. It should be noted that there are two distinct processes at work: (1) the process of involution or invagination in which one wall of the blastula becomes inverted into the other, and (2) the process of overgrowth by which the archenteron becomes roofed in.

The modifications in gastrulation accompanying increase in the amount of yolk are well seen in amphibians or dipnoans, where the relative amount of yolk is intermediate between that of *Amphioxus* and that in meroblastic eggs. Here again segmentation results in the formation of a blastula but, owing to the far greater amount of yolk stored in the abapical cells, the abapical wall of the blastula is so thick that by no possibility could it be involuted into the interior, as it was in *Amphioxus*. The result is that, to arrive at the stage corresponding to the end of gastrulation in *Amphioxus*, a somewhat different route is followed. Involution begins but makes little headway: overgrowth however takes place actively, the anterior lip of the gastrula growing backwards and roofing in the archenteron just as in *Amphioxus*. A new process however now makes its appearance, for the layer of small-celled ectoderm spreads gradually over the surface of the egg by a process of delamination or splitting off from the large underlying cells. In this way the whole of the large-celled yolky cells come to be completely covered in and the stage corresponding to that of *Amphioxus* with the small blastopore is reached.

In the Amniota below mammals the egg is of similar large dimensions. In the reptiles, it is still possible to recognize distinctly the processes of involution and overgrowth, but they are clearly diminishing in importance and the archenteron to which they give rise is of little moment in the later development. In various reptiles the blastopore has been seen to take on eventually the form of a longitudinal slit, the side lips of which eventually undergo fusion over the greater part of its extent, and the line of fusion remaining marked by a kind of seam or scar along which the outer layer of cells or ectoderm is continuous with the underlying cells. This line along which such continuity exists is termed the primitive streak. In the birds, all obvious involution and overgrowth have disappeared, but there still appears as a conspicuous structure during early stages the primitive streak which reptilian embryology shows to be a last vestige of a blastopore.

In the ordinary Mammalia the early stages of development are, as has already been indicated, greatly modified. The modification is associated with two main causative factors: (1) the loss of the yolk, which is present in the more archaic vertebrates and (2) the development of the egg in a strictly confined space, owing to the presence of the shell-like tightly-fitting zona pellucida, followed, in some mammals, by being imbedded in the substance of the uterine wall. In the relatively primitive Indian tree-shrew *Tupaia*, this confinement of the blastula leads the apical part of its wall, where growth is most active, to dip down for a time into the cavity, and it would appear that this temporary involution of the apical pole in *Tupaia* gives the clue to one of the most puzzling peculiarities in the early development of the typical Mammalia. In such mammals segmentation results in a solid sphere of cells, into the interior of which fluid is secreted by the activity of the outer layer to produce a thin-walled *blastocyst*, distended with fluid and carrying at its apical pole, projecting into the cavity, an

"inner mass" of cells, which later on flattens out and constitutes the most important formative portion of the blastocyst wall. The appearances in *Tupaia* clearly suggest that the inner mass of the ordinary mammal simply represents the actively growing apical portion of the blastocyst wall which had to find space for itself by bulging into the interior of the blastocyst, owing to the blastocyst being unable to expand as a whole.

Mesoderm.—Gastrulation leads to the establishment of the two primary cell-layers, ectoderm and endoderm, but in the vertebrate as in other coelomate animals, these constitute but a small fraction of the total mass of the body: by far the greater part is mesodermal in nature. In *Amphioxus* the mesoderm is represented for a time by a series of coelenteric pouches of endoderm down each side of the body. Each of these becomes isolated, so that they form a series of closed compartments on each side. These are the primitive mesoderm segments, and their cavities are the coelomic compartments. At this stage the mesoderm of *Amphioxus* is comparable in certain ways with that of an annelid worm, but in its further development a striking and highly characteristic difference makes its appearance. In an annelid the coelomic compartments becoming distended with coelomic fluid form the wide body-cavity: their outer and inner walls provide the muscular layer of body-wall and enteric wall respectively: their headward and tailward walls applied to those of their neighbours form the coelomic septa: the portions of their mesial walls, where not separated by interposed alimentary canal, form the dorsal and ventral mesenteries.

The difference seen in *Amphioxus* and in other vertebrates is that each mesoderm segment becomes divided into a dorsal and a ventral portion, which differ markedly in their further development. The dorsal, separated from the corresponding structures of the other side of the body by the interposed spinal cord and notochord, becomes a muscle segment or myotome: its portion of coelome, the myocoele, becomes obliterated by the apposition of inner and outer walls. The ventral portion of the mesoderm segment occupies the space between the endoderm and the body-wall: its portion of coelome forms the splanchnocoele or body-cavity. This ventral portion of the mesoderm—the so-called lateral mesoderm of typical vertebrates—develops two striking differences from the dorsal portion: it loses entirely its original segmentation, the splanchnocoele becoming continuous from end to end, and its outer wall no longer produces muscle. Thus while in the annelid the whole extent of the lateral wall of the body is provided directly with a lining of muscle, in *Amphioxus* this applies only to the dorsal portion. With further development however the myotome extends in a ventral direction, insinuating itself between the splanchnocoele and the ectoderm, and in this way the ventral portion of the body-wall in *Amphioxus*, and other vertebrates, becomes secondarily muscularized.

In the Amniota where, in correlation with the thinness of the blastoderm, the mesoderm segment is flattened out into a sheet of cells, this mesial or paraxial source of mesoderm becomes apparently the chief one, and the mesoderm presents the appearance of growing out from the primitive streak region.

Commonly included with the typical mesoderm is the *mesenchyme*. This is a collective term to embrace cells which, assuming an amoeboid character, creep away from their point of origin in the embryo, wandering through its body, multiplying by fission and behaving as if they were independent organisms. Some of these retain their amoeboid wandering character and constitute the leucocytes: others become erythrocytes or red blood-corpuscles: others become chromatophores: others settle down and form the packing tissue or connective tissue which forms the general framework of the body.

The Skin.—The skin of vertebrates is formed by the ectoderm, with a backing of tough connective tissue traversed in all directions by fine fibres and constituting the dermis. In all members of the group above *Amphioxus* the epidermis, by cell-multiplication, loses its original condition of being only one cell thick. In fish numerous epidermal cells become glandular and secrete slime. From the lungfish upwards, local aggregations of these cells form definite flask-shaped glands, opening by minute pores on the body-surface. These epidermal glands undergo specialization in various directions—salivary glands, poison glands, sweat glands, milk glands, etc. In terrestrial vertebrates the superficial ectoderm cells become converted into keratin, forming a horny layer which obstructs evaporation, and these horny cells are shed from time to time as loose scurf, as coherent flakes, or as a continuous slough (*e.g.*, snakes). In reptiles they form a hard layer, covering underlying bony plates in tortoise-shell or the surface of the head in reptiles generally, or forming, with a dense backing of connective tissue, the scales of ordinary reptiles. Innumerable special developments of the horny layer occur, some of which will be found described in other articles: such are claws, feathers, hair, hoofs, rhinoceros horn, whalebone, etc.

The Nervous System, concerned with the relations of the individual to the outer world, develops, as might be expected, from the ectoderm. Normally its first rudiment in the embryo consists of a thickening of the ectoderm along the dorsal surface—the medullary plate. As development proceeds the edges of this curl upwards as the neural folds and these arching in towards one another, convert the originally flat plate first into a groove and later, by fusion of its edges in the mesial plane, into a closed neural tube. Of this, the portion in the head region becomes greatly enlarged to form the brain, while the remainder gives rise to the spinal cord. The brain was formerly described as differentiating in the form of three dilatations of the neural tube one behind the other, the so-called primary brain vesicles, giving rise to fore-, mid-, and hind-brain. Modern advances in comparative embryology show that this is not accurate. In most of the more primitive holoblastic vertebrates the brain first becomes differentiated into an anterior cerebrum and a posterior rhombencephalon, demarcated from one another by an upward fold of the brain floor. Of these the former becomes later differentiated into the thalamencephalon in front and the mesencephalon behind. The cerebral hemispheres, which in the higher mammals assume great importance, seem to arise primitively as paired outward bulgings of the side-wall of the brain towards its front end—related to the sense of smell. The main part of the thalamencephalon undergoes thickening of its side-walls (optic thalamus) while its roof becomes for the most part degenerate, forming a thin membrane in intimate contact with a network of blood-vessels (choroid plexus) lying immediately outside it. At its hind end an outgrowth—the pineal body—develops which may remain a simple club-shaped or tubular structure, but in several cases becomes differentiated into two portions, the anterior of which (parapineal) develops into an eye (*Sphenodon*, various lizards).

In front of the fold of the brain-floor already alluded to, the floor of the thalamencephalon dips down as the infundibulum, and this becomes in the course of development closely associated with an independent structure—the pituitary body. In the more typical vertebrates the two become inextricably involved with one another and it is customary to speak of the nervous part of the pituitary body. The pituitary ingrowth of the ectoderm is typically a hollow pocket and in the surviving crossopterygians it retains this form through life, forming a gland which opens into the buccal cavity. In those vertebrates in which yolk is present at the site of its formation, the pituitary ingrowth is, as in other such cases, solid, developing its cavity secondarily.

The organs of special sense arise as localized developments of the ectoderm. In the case of the olfactory organ and the auditory organ, the rudiment shows first as a localized thickening of the ectoderm, which then, through extension in area, becomes involuted below the surface of the skin as a saucer-like depression. Finally, the opening to the exterior becoming gradually constricted, the organ assumes the form of a more or less completely closed vesicle. In the case of the olfactory organ the closure is never complete, the function, that of chemical testing of the surrounding medium, necessitating free communication between its cavity, in the lining of which the sensory cells develop, and the outside. In the majority of vertebrates however partial closure takes place, to divide the opening into two—one at each end of the organ—and so render possible the drawing in of a current of the external medium through the organ. The first vertebrates that

have this power of "sniffing" are the lungfishes and the origin of the arrangement which makes this possible is well seen in *Protopterus*, where the opening of the olfactory organ narrows, except at its two ends, so as to form a slit. The edges of the slit then undergo fusion and the original single opening is now represented by two separate openings a considerable distance apart. As the anterior boundary of the buccal cavity becomes delimited, one, the anterior or external naris, is left outside and the other, posterior or internal naris, is enclosed within the buccal cavity, perforating its roof. In terrestrial vertebrates in general the olfactory organ becomes similarly provided with external and internal nares, though the process of development shows various modifications in detail.

The early stages of development of the otocyst or rudiment of the auditory organ, are similar to those of the olfactory organ, but the reduction of the external opening goes further: in fact in all vertebrates except elasmobranchs, it becomes completely closed. The peculiar feature which distinguishes the vertebrate is that the usually pyriform otocyst of early stages undergoes a complicated process of modelling, whereby its wall comes to project into three hollow ridges situated in planes perpendicular to one another. The basal or attached portion of each of these becoming obliterated except at its two ends, the ridge is converted into an arched tube—the semicircular canal—opening at each end into the cavity of the otocyst and filled, like the rest of the otocyst, with watery endolymph. In all except the most archaic vertebrates, the otocyst undergoes a still further process of modelling whereby its lower portion (saccule), which develops a special pocket-like outgrowth devoted to the sense of hearing, becomes more or less completely constricted off from the upper portion or utricle, carrying the semicircular canals.

The vertebrate eye differs from the other sense-organs in that its main portion—that containing the actual sensory cells—is developed, not from the external ectoderm, but from the involuted portion of the ectoderm which forms the brain. In a typical case, as in a bird embryo, the optic rudiment consists in its earliest stage simply of the lateral portion of the wall of the thalamencephalon, which here extends outwards on each side so as to give the brain a T-shape. As development proceeds the optic rudiment becomes narrowed at its base to form the optic stalk, which later will become the optic nerve. The distal dilated portion gives rise to the retina, while the region of external ectoderm in contact with its outer end gives rise to the lens. In a typical case, *e.g.*, a bird, the lens is at first simply a slight thickening of the ectoderm, but this soon sinks inwards to form a saucer-shaped depression of the surface, which, by a gradual narrowing of its opening, becomes converted into a closed vesicle. The deep wall of this becomes greatly thickened, its individual cells becoming tall and columnar, and gradually takes on the form of a biconvex lens, the outer wall forming a thin layer of epithelium covering its outer surface. As development goes on the cells of the lens become keratinized and transparent

Meanwhile the original optic rudiment is undergoing differentiation. Its distal portion next the lens becomes involuted within the proximal portion, so that the whole rudiment now takes the form of a double-walled optic cup the mouth of which is blocked by the lens. The inner wall of the cup increases much in thickness and gradually assumes the immense complexity characteristic of the functional retina, of which the most striking peculiarity is that the visual cells are situated on its deep face, the sensory rods facing not towards the lens but away from it—so that rays of light have to traverse the whole thickness of the retina, which is therefore necessarily transparent. On the other hand, the nerve-fibres which pass from the retina to the brain emerge from the retina on its face next the lens, instead of from its deep face as one would expect. This extraordinary reversal of the vertebral retina is at once explained by the method of its development, the deep surface carrying the rods having been originally, before the involution of the brain-rudiment took place, part of the outer surface of the head.

The outer layer of the optic cup undergoes none of the complicated histogenesis seen in the retina. It persists as a single layer of polygonal cells which show their sensitiveness to light by the deposition of granules of dark melanin pigment in their cytoplasm, and in the fully developed condition by characteristic reactions to light stimulus. They constitute what is termed the pigment-layer of the retina.

The ectodermal lens and retina, which constitute the essential optical part of the eye, become ensheathed during development by a thick coating of connective tissue or mesenchyme. This, in its outer layers, becomes condensed into the tough protective wall of the eyeball, the part between the lens and the surface of the head becoming clear and transparent (cornea) while the remainder becomes white and opaque (sclerotic). Between the sclerotic and the pigment layer of the retina there is a rich development of blood-spaces and of dark melanin, which gives its characteristic appearance to the choroid.

The peripheral nerves, i.e., the bundles of nerve fibres which serve as pathways for the nerve impulses, have provided one of the most contentious chapters in vertebrate embryology. A common observation in studying sections of early embryos is that of nerve-trunks springing from the central nervous system and apparently terminating in a free end. Such appearances naturally suggest the view—associated especially with the name of the German anatomist His—that the nerve-fibre actually develops in the embryo as an outgrowth from a nerve-cell, at first ending freely and growing gradually through the intervening connective tissue till it establishes secondarily continuity with its end-organ. This outgrowth view of the mode of development of nerve fibres has in its favour by far the greater volume of observations, including, in recent years, very interesting observations by Harrison and others of an experimental kind. (*See* NERVOUS SYSTEM.)

Alimentary Canal.—The alimentary canal of the vertebrate is seen in its simplest form in the archenteron of the *Amphioxus* embryo. Its wall consists of endoderm, and it possesses a single opening to the exterior—the blastopore. With further development there comes to exist the tubular alimentary canal, in which the layer of endoderm cells forms merely a lining ensheathed by a much thicker mesoderm coat. The wall of the alimentary canal in this more complex definitive state is spoken of as the splanchnopleure or gut-wall, in contradistinction to the somatopleure or external wall of the body. The common error should be avoided of restricting these terms to the mesodermal constituent of the gut and body-wall. The alimentary canal of the vertebrate is in its early stages closed anteriorly, the mouth being a secondary perforation. As in many other animals, the portion of external surface in the region of the mouth becomes involuted to form the lining of the buccal cavity, so that the protective and glandular functions of the skin extend inwards into the first portion of the alimentary canal. The buccal cavity of the vertebrate is therefore morphologically a stomodaeum. For a time, in many vertebrate embryos, the stomodaeal involution remains isolated from the rest of the alimentary canal by a thin partition, covered on its buccal face by ectoderm, on its enteric face by endoderm. This partition eventually ruptures and disappears, although in *Amphioxus* it remains distinctly visible as the velum, perforated in its centre by a circular opening.

The most important features to note in the buccal cavity of the vertebrate are the organs in its lining which have been brought in from their original position on the outer surface of the head. Amongst these are glands which become of special importance in terrestrial vertebrates, where their watery secretion serves to keep moist the buccal lining and in certain cases play a preliminary part in the digestive process, as the salivary glands. Still more conspicuous however are the placoid scales, which, in the primitive elasmobranch scattered all over the outer surface of the body, are also recognizable in the buccal lining. Around the margin of the jaw a series of these placoid scales become specially enlarged, forming the teeth of the adult. The embryology of the elasmobranch then demonstrates that the teeth of vertebrates are vestiges of the placoid scales on the surface of the body.

The buccal cavity is continued into the pharynx, characterized in all vertebrates by the development of (1) the gill-clefts and (2) the thyroid. The gill-clefts, normally six in number, arise as

pocket-like extensions of the pharyngeal wall (visceral pouches), which at their tips undergo fusion with the external ectoderm and open to the exterior, the original visceral pouch becoming thus converted into a visceral cleft, lined with endoderm except towards its outer end, where the lining is ectodermal. The cleft-lining, in view of its respiratory function, undergoes increase of area by growing out into folds (respiratory lamellae) and develops a rich blood-supply.

Comparative embryology shows interesting differences in the details of development of the gill-clefts, and in their ultimate fate. A common variation is that the individual cleft is at first solid and only secondarily becomes hollow: this is the case where the pharynx is in its early stages solid and yolk-laden (teleostean, fish, lungfish, amphibians).

Visceral cleft I. develops in all gnathostomes characteristic differences from the others. In elasmobranchs its respiratory lamellae are reduced to the vestigial pseudobranch on its anterior wall, its function being, as in crossopterygians and sturgeons, that of a mere passage for the water of respiration. In Dipnoi its outer ectodermal end forms a sensory organ (organ of Pinkus) embedded in the side of the head. In these and in all terrestrial vertebrates, it has lost its communication with the exterior. In anurous amphibians and in all amniotes it expands towards its outer end into a wide tympanic cavity lying immediately under the skin so as to allow a wide flat area of the latter to vibrate freely (tympanic membrane or ear-drum). The pharyngeal portion of the cleft remains as the narrow Eustachian tube, providing a means of keeping the air-pressure equal on the two sides of the ear-drum.

While the presence of pharyngeal visceral clefts constitutes one of the most striking vertebrate characteristics, the evidence of comparative anatomy clearly indicates that the series of clefts is undergoing a gradual process of reduction. This is shown by the diminishing number of clefts present in the series *Amphioxus*—cyclostomes (up to 14 in *Bdellostoma*)—Gnathostomata. Embryology shows us this process of reduction actually at work. In various elasmobranch embryos vestigial pouches appear behind those which actually develop into clefts. In teleosts the vestigial spiracular rudiment flattens out while its pseudobranch remains visible on the inner surface of the operculum, thus appearing in the adult as if it belonged to visceral cleft II. The operculum of fishes above elasmobranchs is simply the exaggerated valvular flap formed by the outer edge of visceral arch II. (hyoid) which grows back to cover the visceral clefts further back in the series.

The thyroid, an equally characteristic development of the vertebrate pharynx, arises as a mid-ventral downgrowth of the pharyngeal floor about the level of the hyoid arch. This rudiment, arising either as a hollow pouch or as a solid structure which develops a cavity secondarily, soon becomes isolated from the pharynx as a closed vesicle, and this in turn becomes subdivided up into a multitude of little spherical sacs of endoderm separated by mesenchyme, in which there arises a rich network of blood-spaces. The endodermal epithelium is glandular, producing a clear colloid secretion which distends the numerous rounded vesicles. In its later development the thyroid differs in different vertebrates. It may, as in teleostean fishes, become diffuse and no longer recognizable as a compact organ, while in tetrapods it retains its compact form but becomes more or less completely separated into a right and left lobe.

The clue to the evolutionary history of the thyroid is given by the embryology of the lamprey (*Petromyzon*), in the larva of which it is recognizable as an endostyle, an organ known also in *Amphioxus* and Tunicates.

The Lung, a characteristic feature in the main groups of Vertebrata above the elasmobranchs, arises normally from a rudiment very similar to that of the thyroid, only situated further back, about the hinder limit of the pharynx. Normally unpaired at first, the rudiment soon divides into right and left branches. In simple urodeles each lung remains a thin-walled membranous sac, but in other tetrapods increase in area of the endodermal respiratory lining is brought about by its bulging out into more and more complicated recesses, culminating in large reptiles and in mammals in a spongy texture. In birds, the endoderm-lined cavities of the lung become converted into fine tubular channels (air-capillaries) interwoven with the blood-capillaries and constituting the most highly evolved respiratory organ known. To enable it to function, a bellows-like arrangement is formed by pocket-like outgrowths of the lung-wall which become greatly dilated and constitute the air-sacs. Portions of these grow out into the substance of the bones, replacing the bone-marrow, while others extending in among the muscles of flight provide a mechanism whereby air is automatically passed in and out through the air-capillaries during flight. In *Polypterus*, the most archaic teleostome, the left lung lags behind in development, while the right grows actively and in its posterior portion takes up a medio-dorsal position. This is related to the hydrostatic function of the air-filled lung and is of great interest as indicating, when taken in conjunction with the development of the lung of Dipnoi, that the air-bladder of the modern teleostean fish is simply the persistent right lung, the left having completely disappeared.

The post-pharyngeal portion of the alimentary canal forms the digestive tube and in different vertebrates undergoes varying degrees of differentiation into distinct parts. The more archaic gnathostomes — elasmobranchs, crossopterygians, Dipnoi — are characterized by having a very short straight intestine provided with a spiral valve, and embryology shows that this is preceded by a stage in which the endodermal tube is relatively elongated and coiled into a tight corkscrew spiral, the turns of the spiral being later cemented together and hidden in an enveloping sheath of connective tissue.

The great glands of the intestine arise in the embryo as pocket-like diverticula of its wall. The pancreas is peculiar in that it arises normally from three distinct diverticula—a pair situated ventrally in the neighbourhood of the bile-duct, and the third dorsal. The pancreas of the adult is formed by the fusion of these three rudiments and it may retain (birds) all three openings to the intestine, *i.e.*, three distinct pancreatic ducts.

Coelomic Organs.—The dorsal portions of the mesoderm segments or myotomes form the primitive muscular equipment of the vertebrate. In *Lepidosiren* both lateral and mesial walls of the myotome undoubtedly become converted into myoblasts or muscle cells, but in most vertebrates the phenomena are obscure and many hold that only the mesial wall gives rise to muscle, the outer breaking up into mesenchyme. In *Lepidosiren* the early myoblast has the form of a typical myo-epithelial cell continued into the central nervous system by a protoplasmic tail and it is seen that the so-called end-plate of the motor nerve is simply a portion of the muscle fibre which retains its original protoplasmic condition.

The Myotomes form the foundation of the whole system of voluntary muscles. In fish they remain conspicuous through life. In elasmobranch embryos it is possible to observe the musculature of the limbs sprouting out from the lower ends of certain myotomes. In the higher vertebrates the myotomes are conspicuous in the embryo, but in the adult they are no longer recognizable.

The Splanchnocoele or body-cavity becomes normally subdivided into a smaller pericardiac and a larger peritoneal cavity. In some of the more archaic vertebrates, *e.g.*, elasmobranchs, the two cavities remain continuous through a narrow pericardio-peritoneal canal.

The loss of the primitive coelomic segmentation has brought with it characteristic modifications in the development of the archinephros or series of nephridial tubes.

Incidentally it should be noted that confusion is apt to arise owing to the term nephridium having come to be used in two different senses. The term was invented by E. Ray Lankester (1877) as the equivalent of renal or kidney tubule. It is in this original sense that it is used here. Many writers however, following E. S. Goodrich, separate off renal tubules possessing an open funnel (coelomostome) at their inner end under the separate name coelomoduct.

It is a normal characteristic of the embryo of metamerically segmented animals that the head end, with its special nerve centres and sense-organs, develops first, the process of develop-

ment spreading slowly tailwards, and this principle applies to the nephridial tubes as to other organs. The disappearance of the coelomic septa in the Vertebrata has however eliminated the necessity of each segment having its independent pair of drainage tubes. There has accordingly come about a loss of the serial regularity in the development of the nephridial tubes and these tend to develop in three successive batches, known as pronephros, mesonephros and metanephros. Of these the pronephros is the functional kidney in the early stages of those vertebrates in which these stages are free-living (larval). Where, on the other hand, early development is embryonic, it no longer becomes a functional organ, the excretory products presumably passing away by diffusion from the extensive network of blood-vessels on the surface of the yolk. The pronephros is purely larval: eventually it atrophies, a pair of its nephrostomes however persisting in greatly enlarged form as the ostia or internal openings of the oviducts. The excretory function is now carried out by the series of tubules extending back to the region of the cloaca and termed the opisthonephros. In the fishes and amphibians, this constitutes the kidney of the adult, though already in many of these, *e.g.*, elasmobranchs and urodeles, there is seen a tendency for the excretory function to become concentrated in the hind portion of the opisthonephros, its front portion remaining small and serving for the transmission of the spermatozoa. This condition foreshadows that of the Amniota in which the opisthonephros has become completely divided into mesonephros and metanephros. The former, representing the greater part of the opisthonephros, acts as the functional kidney during embryonic life but later becomes purely reproductive, forming the epididymis attached to the testis. The metanephros—the extreme hind end of the opisthonephros, in which the tubules become greatly increased in size and number—alone forms the kidney of the adult amniote.

The renal organs of vertebrates present many other features of embryological interest. In various of the more archaic types the rudiments of the first pronephric tubules, in the form of little outgrowths of the somatic endoderm, bend backwards at their outer ends and become joined together, forming in this way the rudiment of a longitudinal duct (archinephric duct) which gradually extends back, receiving the successive tubules which undergo fusion with it, and eventually opens into the cloaca. This opening of the tubules into a longitudinal duct instead of directly to the exterior constitutes one of the striking differences between the Vertebrata and the Annelida.

In elasmobranch fishes the archinephric duct becomes split longitudinally into two—a Müllerian duct, into which opens the persistent pronephric nephrostome, and a Wolffian duct, into which open the tubules of the opisthonephros. Functionally, the former becomes the oviduct. In the Amniota the functional tubules of the metanephros open into a third duct—the ureter—while the Wolffian duct now functions exclusively as a vas deferens or male genital duct.

As regards the evolutionary history of these ducts, the known facts of embryology support the view that (1) the archinephric duct came into existence through the external opening of each tubule becoming shifted back so as to open into its successor, (2) the Müllerian and Wolffian ducts became separated by a process of splitting, and (3) the ureter arose from the collecting tube or trunk portion of the large tree-like mass of tubules constituting the metanephros and formed by the enlargement and branching of the last tubule of the opisthonephros.

Finally a noteworthy feature of the renal organs of vertebrates is that the portion of coelome in proximity to the nephrostome tends to become isolated as a small spherical chamber, the Malpighian body: a small portion of the lining of this, in which the power of secreting watery coelomic fluid has become specially concentrated, bulges into the cavity of the Malpighian body as the spherical glomerulus containing an arterial network supplied from the dorsal aorta. The separation of Malpighian body from the main splanchnocoele becomes more and more pronounced as the evolution of the renal organs proceeds.

The Gonad—ovary or testis—is, as in other groups, a development of the coelomic epithelium. Situated just ventral to the segmented portion of the mesoderm, it shows in a few cases distinct traces of segmentation in early stages of its development. In the female, the reproductive cells (eggs or macrogametes) are still shed into the splanchnocoele, finding an exit through the Müllerian ducts. In the male, however, the fertile portion of coelomic epithelium (testis) becomes shut off as an isolated chamber into the cavity of which the reproductive cells (spermatozoa or microgametes) are shed. They eventually reach the vas deferens by way of fine tubular channels (vasa efferentia), which arise in the embryo as outgrowths from the wall of certain of the Malpighian bodies.

The mesenchyme cells, distributing themselves through the body of the embryo, settle down into spongy connective tissue which forms a support and backing to the various developments of ectoderm and endoderm. As development proceeds, special tracts take on special characters—fatty tissue, tendon, ligament and so on—but there are two developments of the mesenchyme which are of special importance. One of these is characterized by its strands becoming hollow vessels in which fluid circulates, the other by its strands becoming rigid and constituting a skeletal or supporting framework to the body.

The Vascular System may be regarded as a development of the intercellular chinks containing the watery "internal medium" or lymph which bathes the surface of all the living cells of the body. The precise mode of origin of the individual vessel appears to differ in different cases. In a particularly clear case, that of the dorsal aorta of *Polypterus*, the lumen of the vessel makes its appearance within a multinucleate protoplasmic strand as fluid vacuoles, which gradually coalesce and form a continuous cavity filled with clear watery fluid. In some cases the main vessels are laid down and circulation begins while the contents are still solely fluid, but soon the fluid becomes peopled by cells which become gradually differentiated, some as erythrocytes, others as leucocytes of various kinds. The origin of these corpuscles varies: in some cases they may be seen to be budded off by the wall of the vessel: in other cases the vascular rudiment at a particular point forms a solid mass of cells (blood-island), the inner of which become separated by fluid to form corpuscles while those on the surface remain in continuity to form the endothelial wall of the vessel.

The detailed study of the later development of the blood-system shows that it provides one of the most interesting chapters in vertebrate embryology. The fundamental plan is seen to be that of two main longitudinal blood vessels, one ventral to the alimentary canal, in which the blood runs forwards, and one dorsal (dorsal aorta), in which the blood streams in a tailward direction, these two longitudinal vessels being connected by a series of hoop-like aortic arches, situated between the gill-clefts, in which the blood passes from the ventral vessel to the dorsal. The vertebrate heart consists of the portion of the ventral vessel immediately behind the pharynx, in which contraction of the vessel wall, elsewhere comparatively inconspicuous, becomes greatly exaggerated and occurs rhythmically throughout life.

The heart or cardiac tube is that part of the ventral vessel which is contained within the pericardiac chamber. At first straight, its rapid increase in length, combined with the fact that it is fixed at each end where it traverses the pericardiac wall, causes it to assume a characteristic S-shaped curvature. As may be well seen in the embryo of a fowl during the third day of incubation, waves of contraction pass forwards along the cardiac tube, propelling the blood in its interior forwards towards the aortic arches. As development proceeds the originally uniform cardiac tube becomes at intervals relatively enlarged to form a series of four dilatations, demarcated from one another by relatively less dilated portions. These four dilatations become the sinus venosus, atrium, ventricle and conus arteriosus. With this morphological change in diameter comes a physiological change in that the originally uniform wave of contraction becomes replaced by serial contractions of each chamber in turn. As development proceeds further, the four chambers become compacted together and the original tubular shape of the heart is completely lost. The pumping activity of the heart becoming more and more concentrated in the ventricle, the muscular wall of this part becomes

much more highly developed than that of the others.

To secure that the blood stream flows in the proper direction a valvular apparatus becomes developed in the interior of the heart and this, in its earliest stages, takes the form of longitudinal ridge-like thickenings of the inner layer of the heart-wall. These are best seen in the conus arteriosus, where they are normally four in number and where they are jammed together when the conus contracts, obliterating its cavity and so preventing any backward suction when the ventricle dilates. These endocardiac ridges, dependent for their efficiency upon physiological activity, become in such relatively archaic vertebrates as elasmobranchs and ganoids converted into a purely mechanical apparatus which works automatically, each ridge becoming segmented into a row of valves shaped like watch-pockets, with their openings directed towards the head. These flatten against the wall when the blood streams forwards, but open out and occlude the cavity by their edges coming in contact the moment the blood tends to regurgitate. In the air-breathing vertebrates from lungfish upwards, the conus with its valvular apparatus undergoes an extraordinarily interesting series of evolutionary changes. In the lungfish the conus is relatively long and is bent into a characteristic Z-form. Along its interior run the four endocardiac ridges. Two of these, the right and the left, project as thin blade-like structures more than halfway across the lumen, their free edges overlapping so that they subdivide the cavity into two portions, one dorsal and one ventral. The two cavities are continued forwards into the ventral aorta by a horizontal partition which extends as far forwards as the level of aortic arch V. where it merges into the roof of the ventral aorta. Aortic arches V. and VI. take origin from the dorsal or pulmonary cavity, while the remaining aortic arches spring from the continuation forwards of the ventral cavity. The atrio-ventricular portion of the heart also has its cavity divided, in this case by a vertical septum projecting forwards from its posterior wall. This septum is incomplete, not extending completely across the atrio-ventricular cavity except when the wall of this part of the heart is contracted. Owing to the peculiar flexure of the conus, its incomplete septum—horizontal at its front end—becomes at its ventricular end vertical and in line with the atrio-ventricular septum. The result is that, in the contracted condition of the ventricle, the right half of its cavity is continuous with the right half of the cavity of the conus and this cavity, owing to the peculiar flexure, ends off at its headward end by being dorsal, *i.e.* continuous with the pulmonary cavity of the ventral aorta. Correspondingly the left ventricular cavity is continued through the conus to the ventral or systemic cavity of the ventral aorta.

In the tetrapods the conus develops similar endocardiac ridges to those seen in lungfish, but the conus has now greatly shrunken in length, with the result, owing to its ends being fixed, that the Z-flexure is drawn out and replaced by a spiral twist. Further, in the Amniota, the two prominent ridges, which in the lungfish merely overlap, undergo complete fusion, so that the cavity of the conus, as of the ventral aorta, becomes divided completely into pulmonary and systemic cavities, continuous respectively with the right and left ventricles, which also become completely separated during development. In the higher Amniota the septum so formed in the conus becomes itself split, so that the conus comes to be represented by two separate vessels, pulmonary and systemic, spirally twisted round one another.

Of all features in the development of the blood system of vertebrates, perhaps the most interesting is that the great arteries of the higher amniotes repeat in the course of their development the series of aortic arches between the visceral clefts. Although the bird or human being will never use its gill-clefts for breathing, yet it shows for a time the typical piscine arrangement of aortic arches. As development proceeds, large tracts of this primitive scheme disappear while others persist and become straightened out into the great arteries of the adult.

The venous system of the vertebrate shows also many features of interest in its embryology. Perhaps the most important of these is that the venous system of the higher vertebrates shows for a time in the embryo the same main trunks—duct of Cuvier, anterior and posterior cardinal veins—as those of an adult fish. The main new development in the venous system of tetrapods, the inferior or posterior vena cava, presents the striking peculiarity that it has a double origin in the embryo, its anterior portion being associated with the liver and its posterior portion with the posterior cardinal veins. This points to the posterior vena cava having originated in evolution from an arrangement similar to that of modern dipnoans, where the anterior end of the opisthonephros is fused with the tip of the liver, thus rendering possible the direct passage of blood from kidneys to heart through the liver substance.

The Skeletal System of the vertebrate is shown by embryology to present three evolutionary phases: (1) notochordal, (2) cartilaginous, (3) bony. The notochord arises as a rod of cells split off from the endoderm along the mid-dorsal line. The notochordal cells, except the superficial layer, become greatly vacuolated and their turgidity gives stiffness to the notochord as a whole. The superficial layer of cells (notochordal epithelium) produces a cuticular primary sheath and later, internal to this, a thicker secondary sheath. In craniate vertebrates a further step in skeletal development is the modification of patches of connective tissue to form cartilage. In the trunk region these appear first as the paired rudiments of neural and haemal arches, two pairs of each in the lower types within the length of a single muscle segment. In two of the more archaic groups, Elasmobranchii and Dipnoi, cartilage cells from the arch-rudiment burrow through the primary sheath and colonize the secondary sheath of the notochord. The notochord thus becomes enclosed in a cylinder of cartilage, which in the elasmobranch becomes segmented into vertebral centra, each carrying two pairs of neural and of haemal arches. In other vertebrates this invasion of the secondary sheath by cartilage cells does not take place, and the centra arise outside the primary sheath by expansion of the bases of the arches. In the head region traces of cartilaginous vertebrae can be traced in various archaic vertebrates as far forwards as the tip of the infundibulum, the hinder region of the cranium representing a part of the axial skeleton in which the vertebral segmentation has disappeared and the neural canal become greatly enlarged in correlation with the expansion of the central nervous system to form the brain. As regards the pre-chordal or trabecular portion of the cranium, embryology does not provide any definite evidence as to its relation to the trunk skeleton. The olfactory organ and the otocyst each becomes enclosed in a capsule of cartilage and these become incorporated in the complete cranium. Apart from the axial skeleton cartilaginous elements make their appearance in relation to the visceral arches (*see* VERTEBRATA) and to the limbs, each showing in their development many details of interest.

The bony skeleton makes its first appearance in the isolated placoid scales of elasmobranchs, some of which, it will be remembered, are carried into the buccal cavity, either remaining of small size or becoming enlarged to form the teeth. In various of the lower vertebrates, especially urodele amphibians, embryology demonstrates that the bones which underly the base of the cartilaginous cranium and reinforce it are formed of originally separate placoid denticles, which become united into a continuous plate by the spreading out and fusion of their basal portions. In some cases only part of the bone may show this dental origin, the denticles having disappeared from the rest. In other cases bones which in Urodeles have this dental origin develop in Anura without showing denticles. Such and many similar facts of embryology have suggested the working hypothesis that the bony skeleton had its evolutionary origin in the primitive dermal equipment of placoid scales.

Adaptations to Environment.—An interesting chapter of vertebrate embryology deals with the environmental conditions amid which the various types of vertebrate pass through their early stages and the ways in which the young vertebrate is adapted to these conditions. In certain cases the environment and the young individual's relations to it present no special peculiarities. The young crossopterygian or lungfish or urodele leads a normal kind of aquatic existence and the strikingly uniform type of larva in these three relatively archaic vertebrates suggests strongly that

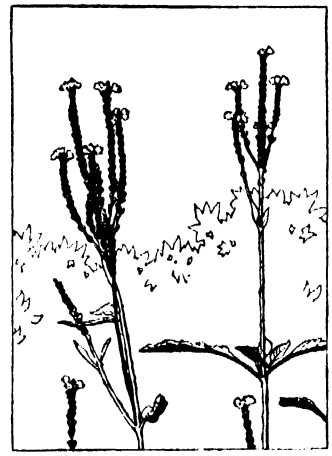
it repeats an early stage of vertebrate evolution. In most vertebrates however, development is either embryonic or secondarily larval. In elasmobranchs, in teleosts and in reptiles and birds, the early stages are passed within the shelter of egg-envelopes and this involves the modifications associated with the storing up of a supply of yolk—modifications which still persist in cases such as the majority of teleosts, where a larval mode of development is re-acquired. Embryonic development is seen in its highest expression in the terrestrial vertebrates and these, in addition to the immense exaggeration of the ventral part of the endoderm to store up yolk (yolk-sac), show two other striking peculiarities: (1) the body of the embryo becomes enclosed in a water-jacket (amnion) in which it floats suspended and is thus protected from the sudden jars incidental to a terrestrial existence, and (2) the allantois—the pouch-like outgrowth from the hinder part of the alimentary canal which in the amphibian functions as a urinary bladder—becomes precociously enlarged and, spreading round the inner surface of the egg-shell, constitutes the breathing organ during a large part of embryonic life. The highest degree of adaptation to the terrestrial existence is reached by the ordinary mammals, in which the egg, instead of being laid at an early stage of development, is retained within the mother's uterus for a prolonged period during which the embryo passes through all the earlier helpless stages of its development. The yolk-sac, amnion and allantois are still present as in the reptiles. But the allantois has developed a new function, that of absorbing nourishment from the uterine wall, and in correlation with this, the supply of yolk, which in the reptilian egg was so conspicuous, has now disappeared practically entirely. The yolk-sac still retains its old features but it now contains merely lymph. And, correlated with this in turn, the mammalian macrogamete or zygote has shrunk to a size comparable with that of *Amphioxus*. Whereas the unsegmented egg of an ostrich measures as much as 85 mm. in diameter that of man has reverted to as little as 0·25 mm.

BIBLIOGRAPHY.—J. Graham Kerr, *A Text-book of Embryology*, vol. ii.: "Vertebrata with the exception of Mammalia" (London, 1919); this book gives an account of the general principles of Vertebrate Embryology based on the study of the lower vertebrates and includes the results of modern investigations upon the embryology of some of the more primitive types. Includes a guide to the bibliography of the subject and to its practical technique; A. Brachet, *Traité d'Embryologie des Vertébrés* (Paris, 1921), a good modern text-book on Embryology of Vertebrates, including the Mammalia; contains bibliography.

(J. G. K.)

VERTICAL, the direction of the line of action of gravity, as determined by the plumb-line. *The angle of the vertical* is the angle between the direction of the plumb-line and the direction towards the earth's centre (*see* EARTH, FIGURE OF THE).

VERTIGO: *see* MÉNIERE'S DISEASE; SEASICKNESS.



VERTUE, GEORGE (1684–1756), English engraver and antiquary, was born in St. Martin's-in-the-Fields, London, in 1684. At the age of 13 he was apprenticed to an heraldic engraver, a Frenchman, who failed in three or four years. Vertue then studied drawing at home, and afterwards worked for seven years as an engraver under Michael Vandergucht. His plate of Archbishop Tillotson, after Kneller, commissioned by Lord Somers, established his reputation as an engraver; and he was soon in an excellent practice, engraving portraits after Dahl, Richardson, Jervas and Gibson. In portraiture alone he executed over 500 plates. In 1717 he was made engraver to the Society of Antiquaries. He died on July 24, 1756, and was buried in Westminster Abbey.

Vertue's forty volumes of memoranda on the history of British art were purchased by Horace Walpole, and form the basis of that author's *Anecdotes of Painting in England*, including an account of Vertue's life and a catalogue of his engravings.

VERTUMNUS, in Roman cult, the god of the changing year (Lat. *vortumnus*, changing) with its seasons, its flowers and its fruits, probably of Italian origin. In legend, he has the power of assuming any shape he pleases, which enables him to win the love of Pomona (*q.v.*). His shrine and statue (*see* the description in Propertius iv. 2) were in the Vicus Tuscus, and from his connexion with this busy street he was regarded as having a special interest in trade and barter. At another sanctuary on the slope of the Aventine, sacrifice was offered to him every year on Aug. 13.

VERULAMIUM, a Romano-British town situated in the territory of the Catuvellauni, close to the modern St. Albans (Hertfordshire). Before the Roman conquest it was the capital of Tasciovanus, Prince of the Catuvellauni, who issued coins inscribed with the name of the place, and of his son, Cunobelin; afterwards it received the dignity of a *municipium* (implying municipal status and Roman citizenship). Tacitus tells us that the town was burnt by Boadicea (*q.v.*), in A.D. 60 or 61, but it again rose to prosperity. The visit of Germanus to the tomb of S. Alban shows that it was still inhabited in 429. Its site is still easily recognizable. Its walls of flint rubble survive in stately fragments, and enclose an area of 200 acres. Of the internal buildings little is known. A theatre was excavated in 1847, and parts of the forum were opened by Mr. William Page in 1898; both indicate a civilized and cultivated town. The complete uncovering of the site was planned in 1910 but abandoned. (*Royal Comm. on Hist. Monuments, Inventory of Herts.* [1910], pp. 3, 190; *Victoria County Hist. Herts.* IV. [1914].)

VERVAIN (*Verbena officinalis*), a plant of the family Verbenaceae (*q.v.*), native to Europe and Asia, common in the south of England, and naturalized across the continent of North America. It is a smooth slender annual, 1 to 3 ft. high, with opposite, deeply incised leaves and numerous very slender spikes of purplish or white flowers. To the vervain, which was held in superstitious veneration by the ancient peoples of Great Britain, were ascribed remarkable medicinal virtues, which, however, are now wholly discredited. In the United States the name vervain is applied to several native species of *Verbena*, as the white vervain (*V. urticifolia*), the blue vervain (*V. hastata*), the hoary vervain (*V. stricta*), the bracted vervain (*V. bracteosa*), and the spreading vervain (*V. prostrata*). Most of these inter-hybridize.

BY COURTESY OF THE WILD FLOWER PRESERVATION SOCIETY

BLUE VERVAIN (VERBENA HASTATA)

VERVET, a Central and South African monkey, *Cercopithecus pygerythrus*. It is allied to the grivet (*q.v.*), but distinguished by the presence of a rusty patch at the root of the tail and by the black chin, hands, and feet.

VERVIERS, a town, province of Liége, Belgium, on the main line from Liége to Aix-la-Chapelle and Cologne. Pop. (1925) 41,663. It is on the Vesdre, which flows into the Ourthe a few miles before its junction with the Meuse; and the water of that river is supposed to be especially good for dyeing purposes.

VERWEY, ALBERT (1865–), Dutch man of letters, was one of the leading figures of the revival of Dutch literature, called "The movement of 1880." He helped to found and from 1884–89 was one of the editors of the *Nieuwe Gids;* from 1894–1904 of the *Tweemaandelijksch Tijdschrift* and *De XXe Eeuw*, and from 1905–19 of *De Beweging*. In 1924 Verwey was appointed professor of Dutch literature in the University of Leyden. His anthology with commentaries of *Nederlandsche Dichters behalve Vondel* (1893, etc.) and his essay on *Potgieter* and his circle, *Het Testament van Potgieter* (1908) are works of lasting value. Verwey, who held an honorary doctor's degree from the University of Groningen, translated into Dutch Shelley's *A Defence of Poetry*, Sidney's *An Apology for Poetry* (1891) and Shelley's *Alastor* (1922). In 1885 he issued an article on *The Sonnet and the Sonnets of Shakespeare.*

He has published several volumes including *Inleiding tot de nieuwe Nederlandsche dicht Kunst, 1880–1900* (1914); *Proza* (1911 etc.); *De Maker* (1924) and *Rondom mijn Werk, 1890–1923* (1925).

See M. Uyldert, *Albert Verwey* (1908).

VESICA PISCIS, in architecture, the term given to a pointed oval panel formed by two equal intersecting circular

curves; a common form given to a panel in which the figure of Christ is represented. It is employed in mediaeval seals, especially those of bishops and monastic establishments. (*See* also MANDORLA.)

VESNIC, MILENKO (1862–1921), Serbian diplomatist, was born as a Turkish subject in what was then the Sanjak of Novi Pazar, on Feb. 13, 1862, but made his way to Belgrade, where he was educated. After studying law he took his doctorate in Munich. He entered the Serbian diplomatic service in 1891, but soon left it for journalism and teaching. In 1893 he entered Parliament and was for a short time Minister of Education in the Gruijic Cabinet. In 1899 he and other Radical leaders were falsely charged with complicity in the attempt on King Milan's life, and Vesnic was sentenced to two years' imprisonment. After a year he was pardoned, resumed his professorship, and in 1901 became Minister in Rome. In 1904 he was appointed Minister in Paris, a post which he held, with short intervals of political work, until his death. He was one of the delegates sent by King Peter to negotiate the peace of London in 1913, and in 1919 was delegate of the new Yugoslav State at the Peace Conference. In 1920 Vesnic, who remained a Radical, became the head of a coalition cabinet. He died in Paris on May 15, 1921.

VESOUL, a town of eastern France, capital of the department of Haute-Saône, 236 m. E.S.E. of Paris on the Eastern railway to Belfort. Pop. (1926) 9,614. Vesoul is of ancient origin, but in existing records is first mentioned in the 9th century. Originally a fief of the church of Besançon, it passed to the house of Burgundy, becoming, in the 13th century, capital of the bailiwick of Amont. The castle was destroyed in the 17th century. The town suffered much during the wars of religion and the Thirty Years' War. Vesoul belonged temporarily to France after the death of Charles the Bold, duke of Burgundy; was returned to the empire when Charles VIII., king of France, broke off his marriage with the daughter of Maximilian, king of the Romans; and again became part of France under Louis XIV. after the peace of Nijmwegen in 1678. Vesoul stands between the river Durgeon and the isolated vine-clad hill of La Motte (1,263 ft.), crowned by a votive chapel which in 1855 replaced the old fortification. The 13th and 15th century walls of the town still exist on its northern side.

VESPASIAN, in full TITUS FLAVIUS VESPASIANUS, Roman emperor A.D. 70–79, was born on Nov. 18, A.D. 9, in the Sabine country near Reate. His father was a tax-collector and money-lender on a small scale; his mother was the sister of a senator. After having served with the army in Thrace and been quaestor in Crete and Cyrene, Vespasian rose to be aedile and praetor, having meanwhile married Flavia Domitilla, the daughter of a Roman knight, by whom he had two sons, Titus and Domitian, afterwards emperors. Having already served in Germany, in the years 43 and 44, in the reign of Claudius, he distinguished himself in command of the 2nd legion in Britain under Aulus Plautius. He reduced Vectis (isle of Wight) and penetrated to the borders of Somersetshire. In 51 he was for a brief space consul; in 63 he went as governor to Africa, where, according to Tacitus (ii. 97), his rule was "infamous and odious"; according to Suetonius (*Vesp.* 4), "upright and highly honourable." He went with Nero's suite to Greece, and in 66 was appointed to conduct the war in Judaea.

On the first of July, 69, while he was at Caesarea, he was proclaimed emperor, first by the army in Egypt, and then by his troops in Judaea. The legions of the East at once took the customary oath of allegiance. Nevertheless, Vitellius, the occupant of the throne, had on his side the veteran legions of Gaul and Germany, Rome's best troops. But the feeling in Vespasian's favour quickly gathered strength, and the armies of Moesia, Pannonia and Illyricum soon declared for him, and made him in fact master of half of the Roman world. They entered Italy on the north-east under the leadership of Antonius Primus, defeated the army of Vitellius at Bedriacum (or Betriacum), sacked Cremona and advanced on Rome, which they entered after furious fighting, in which the Capitol was destroyed by fire. The new emperor received the tidings of his rival's defeat and death at Alexandria, whence he at once forwarded supplies of corn to Rome, which were urgently needed, along with an edict or a declaration of policy, in which he gave assurance of an entire reversal of the laws of Nero, especially those relating to treason.

Leaving the war in Judaea to his son Titus, he arrived at Rome in 70. He at once devoted his energies to repairing the evils caused by civil war. He restored discipline in the army, which under Vitellius had become utterly demoralized, and, with the co-operation of the senate, put the government and the finances on a sound footing. He renewed old taxes and instituted new, increased the tribute of the provinces, and kept a watchful eye upon the treasury officials. By his own example of simplicity of life, he put to shame the luxury and extravagance of the Roman nobles and initiated in many respects a marked improvement in the general tone of society. By taking over the censorship, the last of the republican magistracies, he gained complete control over the entry to the senate. He altered the constitution of the praetorian guard, in which only Italians, formed into nine cohorts, were enrolled, while Italians seem to have been excluded from the legions; he tended to assimilate the auxiliaries to the legions in personnel. The time-expired men, when they went back to their homes, he made use of to promote the urbanization and Romanization of the more backward and unorganized provinces. In 70 a formidable rising in Gaul, headed by Claudius Civilis, was suppressed and the German frontier made secure; the Jewish War was brought to a close by Titus's capture of Jerusalem, and in the following year, after the joint triumph of Vespasian and Titus, the temple of Janus was closed, and the Roman world had rest for the remaining nine years of Vespasian's reign. In 78 Agricola went to Britain, and both extended and consolidated the Roman dominion in that province, pushing his arms into North Wales and the Isle of Anglesey. In the following year Vespasian died, on June 23.

The "avarice" of Tacitus and Suetonius seems to have been an enlightened economy, which, in the disordered state of the Roman finances, was an absolute necessity. Vespasian could be liberal when he chose, as Quintilian's pension shows. Pliny's great work, the *Natural History*, was written during Vespasian's reign and dedicated to his son Titus. Of the philosophers who encouraged conspiracy by republican theorizing only one, Helvidius Priscus, was put to death, and he had affronted the emperor by studied insults. "I will not kill a dog that barks at me," were words honestly expressing the temper of Vespasian.

Much money was spent on public works and the restoration and beautifying of Rome—a new forum, the splendid temple of peace, the public baths and the vast Colosseum being begun under Vespasian. The roads and aqueducts were repaired, and the limits of the *pomerium* extended.

The most important of his changes in the provinces was the reorganization of the eastern provinces, whereby Judaea became a province of its own, Syria absorbed the vassal kingdom of Commagene and had its legionary forces strengthened and centred at Samosata, and Cappadocia and lesser Armenia were absorbed in Galatia, whose governor also was given legionary troops to hold the upper river, stationed at Melitene; second to this comes the annexation of the *agri decumates*, the first step to cutting out the salient in the Rhine-Danube frontier. Mention may be made of his extension of Latin rights to Baetica.

To the last Vespasian was a blunt soldier, with strength of character, and with a steady purpose to establish good order and secure the prosperity and welfare of his subjects. In his habits he was punctual and regular, transacting his business early in the morning, and enjoying his siesta after a drive. He was free in his conversation, and his humour was apt to take the form of rather coarse jokes. There is something very characteristic in the exclamation he is said to have uttered in his last illness, "An emperor ought to die standing."

Henderson, *Civil War and Rebellion in the Roman Empire,* A.D. 69-70 (1908); *Five Roman Emperors* (1927); M. I. Rostovtseff, *Social and Economic History of the Roman Empire* (1926).

VESPERS, in the Roman Catholic liturgy, the seventh of the eight "hours" which make up the daily office. (*See* BREVIARY.)

VESPERS, SICILIAN, the revolution of the Sicilians against Angevin domination, so called because it broke out at the hour of Vespers on Easter Tuesday 1282. The government of Charles I. of Anjou (*q.v.*) was highly oppressive, and the people of Sicily were strongly attached to the house of Hohenstaufen. The actual outbreak was a purely unpremeditated popular movement. Charles at that time was making preparations for an attack on the East Roman empire, and heavily taxing the Sicilians in order to meet his expenses. Peter III. king of Aragon, wishing to assert the claims to Sicily which he possessed in right of his wife Constanza daughter of Manfred (*q.v.*), was negotiating with the enemies of Charles, when the people of Sicily, goaded beyond endurance, rose unexpectedly against their rulers. On March 31, 1282 a riot broke out in a church near Palermo, in consequence, according to tradition, of the insults of a French soldier towards a Sicilian woman, and a general massacre of the French began. The rising spread to the city, where a republic was proclaimed, and then through the rest of the island; thousands of French men, women and children were butchered (there may be some exaggeration in the wholesale character of the slaughter), and by the end of April the whole of Sicily was in the hands of the rebels. Charles at once led an expedition against the Sicilians and besieged Messina. The island was saved from re-conquest by the intervention of Peter of Aragon, but this intervention changed the character of the movement, and the free communes which had been proclaimed throughout the island had to submit to royal authority and a revived feudalism. Peter, having reached Palermo in Sept. 1282, accepted the Sicilian crown, and declared war on Charles. *See* SICILY; NAPLES.

BIBLIOGRAPHY.—The standard work on the subject is Michele Amari's *Guerra del Vespro* (2 vols. 8th ed., Florence, 1876), which is based on a study of the original authorities, but is too strongly prejudiced against the French; *cf.* L. Cadier's *Essai sur l'administration du royaume de Sicile par Charles I. et Charles II. d'Anjou* (fasc. 59 of the *Bibliothèque des écoles françaises de Rome et d'Athènes*, 1891). *See* also A. de Saint-Priest, *Histoire de la conquête de Naples par Charles d'Anjou* (1847–49); A. Cappelli's preface to the "Leggenda di Messer Giovanni da Procida," in *Miscellanea di opuscoli inediti o rari dei secoli XIV. XV.* (Turin, 1861); F. Lanzani, *Storia dei communi d'Italia*, lib. v. ch. 3 (Milan, 1882).

VESPUCCI, AMERIGO (1451–1512), merchant and adventurer, who gave his name of *Amerigo* to the new world as *America*, was born at Florence on March 9, 1451. His father, Nastagio (Anastasio) Vespucci, was a notary, and his uncle, Fra Giorgio Antonio Vespucci, to whom he owed his education, was a scholarly Dominican and a friend of Savonarola. Amerigo was placed as a clerk in the great commercial house of the Medici, then the ruling family in Florence. A letter of Dec. 30, 1492, shows that he was then in Seville; and till Jan. 12, 1496, he seems to have usually resided in Spain, especially at Seville and Cadiz, probably as an agent of the Medici. In December 1495, on the death of a Florentine merchant, Juanoto Berardi, established at Seville, who had fitted out the second expedition of Columbus in 1493, and had also undertaken to fit out 12 ships for the king of Spain (April 9, 1495), Vespucci was commissioned to complete the contract. As Ferdinand recalled the monopoly conceded to Columbus (this order of April 10, 1495, was cancelled on June 2, 1497), "private" exploring now had an opportunity, and adventurers of all kinds were able to leave Spain for the West. Vespucci claims to have sailed with one of these "free-lance" expeditions from Cadiz on May 10, 1497. Touching at Grand Canary on the way, the four vessels he accompanied, going 37 days on a west-south-west course, and making 1,000 leagues, are said to have reached a supposed continental coast in 16° N., 70° W. from Grand Canary (June 16, 1497). This should have brought them into the Pacific. They sailed along the coast, says Vespucci, for 80 leagues to the province of Parias (or Lariab), and then 870 leagues more, always to the north-west, to the "finest harbour in the world," which from this description should be in British Columbia or thereabouts, thence 100 leagues more to north and north-east, to the islands of the people called "Iti," from which they returned to Spain, reaching Cadiz in October 1498. Still following Vespucci's own statement, he, in May 1499, started on a second voyage in a fleet of three ships under Alonzo de Ojeda (Hojeda). Sailing south-west over 500 leagues they crossed the ocean in 44 days, finding land in 5° S. Thence, encountering various adventures, they worked up to 15° N., and returned to Spain by way of Antiglia (Española, San Domingo), reaching Cadiz in Sept. 1500.

Entering the service of Dom Manuel of Portugal, Vespucci claims to have taken part in a third American expedition, which left Lisbon in May 1501. Vespucci has given two accounts of this alleged third voyage, differing in many details, especially dates and distances. From Portugal he declares that he sailed to Bezeguiche (Cape Verde), and thence south-west for 700 leagues, reaching the American coast in 5° S. on the 7th (or 17th) of August. Thence eastward for 300 (150) leagues, and south and west to 52° S. (or 73° 30′; in his own words, "13° from the antarctic pole," *i.e.*, well into the antarctic continent). He returned, he adds, by Sierra Leone (June 10), and the Azores (end of July), to Lisbon (Sept. 7, 1502). His second Portuguese (and fourth and last American) voyage, as alleged by him, was destined for Malacca, which he supposed to be in 33° S. (really in 2° 14′ N.). Starting from Lisbon on May 10, 1503, with a fleet of six ships, and reaching Bahia by way of Fernando Noromha (?), Vespucci declares that he built a fort at a harbour in 18° S., and thence returned to Lisbon (June 18, 1504). In Feb. 1505, being again in Spain, he visited Christopher Columbus, who entrusted to him a letter for his son Diego. On April 24, 1505, Vespucci received Spanish letters of naturalization; and in 1508 was appointed *piloto mayor* or chief pilot of Spain, an office which he held till his death, at Seville, on Feb. 22, 1512.

If his own account had been trustworthy, it would have followed that Vespucci reached the mainland of America eight days before John Cabot (June 16 against June 24, 1497). But Vespucci's own statement of his exploring achievements hardly carries conviction. This statement is contained (i.) in his letter written from Lisbon (March or April 1503) to Lorenzo Piero Francesco di Medici, the head of the firm under which his business career had been mostly spent, describing the alleged Portuguese voyage of March 1501–Sept. 1502. The original Italian text is lost, but we possess the Latin translation by "Jocundus interpreter," perhaps the Giocondo who brought his invitation to Portugal in 1501. This letter was printed (in some nine editions) soon after it was written, the first two issues (*Mundus Novus* and *Epistola Albericii de Novo Mundo*), without place or date, appearing before 1504, the third, of 1504 (*Mundus Novus*), at Augsburg. Two very early Paris editions are also known, and one Strasbourg (*De Ora Antarctica*) 1505, edited by E. Ringmann. It was also included in the *Paesi novamente retrovati* of 1507 (Vicenza) under the title of *Novo Mondo da Alb. Vesputio.* The connection of the new world with Vespucci, thus expressed, is derived from the argument of this first letter, that it was right to call Amerigo's discovery a new world, because it had not been seen before by any one. This prepared the way for the American name soon given to the continent. (ii.) In Vespucci's letter, also written from Portugal (September 1504), and probably addressed to his old schoolfellow Piero Soderini, gonfaloniere of Florence 1502–12. From the Italian original (of which four printed copies still exist, without place or date, but probably before 1507) a French version was made, and from the latter a Latin translation, published at St. Dié in Lorraine in April 1507, and immediately made use of in the *Cosmographiae Introductio* (St. Dié, 1507) of Martin Waldseemüller (Hylacomylus), professor of cosmography in St. Dié university. Here we have perhaps the first suggestion in a printed book that the newly discovered fourth part of the world should be called "America, because Americus discovered it."

Since Alexander von Humboldt discussed the subject in his *Examen critique de l'historie de la géographie du nouveau continent* (1837), vol. iv., the general weight of opinion (in spite of F. A. de Varnhagen, *Amerigo Vespucci, son caractère, ses écrits . . . sa vie . . .*, Lima, 1865, and other pro-Vespuccian works) has been that Vespucci did not make the 1497 voyage, and that he had no share in the first discovery of the American continent.

VESTA, the Roman hearth-goddess. The name is etymologically identical with Hestia (*q.v.*), but the Roman cult is nearer the primitive conditions. In an early community fire was hard to make, and therefore it was desirable that at least one fire should be kept always burning. This duty would naturally devolve upon the chief or king, and the actual maintenance of the fire would usually fall to his young daughters, since slaves, if he had any, would hardly be trusted with a duty considered holy, he and his sons would be out most of the day, and his wife would be busy with housework. Much of the actual preparation of food would also fall upon the daughters, as soon as they were old enough, for a Roman housewife in early days might not grind corn or cook food for her husband (Plutarch, *quaest. Rom.*, 85). Hence we get, in early historical times, besides the private cult of Vesta and the *di penates* (*q.v.*) in every household, a public cult of a sacred royal hearth, never allowed to go out, tended by girls (Virgines Vestales) whose service begins when they are from six to ten years old (Gellius, i. 12, 1), and lasts originally for five years (Dion. Hal., i. 76, 3), *i.e.*, till they are old enough for marriage, or at least bethrothal. The earliest cult of this kind was supposed to be that at Lavinium; the most famous was at Rome.

In Republican times, the *pontifex maximus* took the place of the king for many sacred purposes. The Vestals, whose number was six, and whose term of service had now been lengthened to 30 years, were in his charge, being freed from the *potestas* of their own fathers. They must, when chosen, be of the required age, free-born of free-born and respectable parents (although later, daughters of freedmen were eligible), having both parents alive (*patrimae et matrimae*), and free from physical and mental defects. The *pontifex* took the candidate by the hand, pronouncing a formula of admission to the sacred office; her hair was cut and the cuttings hung on a certain tree; she was dressed in an ancient costume, identical with that of a bride. From this it does not follow that she was the wife of either fire-god or king (Klausen, Frazer, Wissowa), but rather that the bride's dress was that of a virgin. If a Vestal let the fire go out she was beaten. On such occasions, and also apparently once a year, when it was solemnly extinguished and re-lighted at the New Year (March 1), the fire was re-kindled by friction of wood (the use of a burning-glass, Plut., *Numa.* 9, if Roman at all, is certainly a late innovation). If found guilty of unchastity, she was subjected to an ordeal which amounted to a horrible form of capital punishment; she was shut up with a little food in an underground cell, which was covered over with earth. The Vestals' duties, besides the tending of the fire, comprised the fetching of water from a sacred spring (Vesta would have no water from the city mains), the preparation of sacred food-stuffs (*muries*, or brine, and *mola salsa*, coarse meal mixed with salt) for ritual purposes; also the custody of various holy objects, said to include the Palladium (*q.v.*) in the *penus Vestae* or store-chamber of the shrine of Vesta, which was so holy that no one but a Vestal might enter it. They took part in ceremonies of various kinds, besides Vesta's own elaborate daily ritual. Further, the privileges accorded to the Vestals, and especially those which were extended to their senior, the Virgo Maxima, were those of princesses.

The shrine of Vesta stood in the Forum, near the Regia, or palace of the kings. It was not technically a *templum* but a round structure, a stone imitation of the primitive "bee-hive" hut. When Augustus became *pontifex maximus*, he built a second shrine of Vesta on the Palatine and handed over the Regia to the Vestals. They also had for their quarters the splendid Atrium Vestae, between the shrine and the Velia. Their cult continued in great honour throughout the empire, until the abolition of pagan worship by the Christian emperors. Gratian confiscated the Atrium Vestae in 382. Considerable ruins of both it and the shrine are still to be seen; the former contains numerous statues (all late) of Vestals. The shrine contained no statue, the eternal fire serving instead. Images of Vesta of any kind are rare; when shown in art she is represented as a woman fully draped, sometimes accompanied by an ass.

Her festival, the Vestalia, was on June 9; thereafter, until June 15, the shrine was closed for the annual ceremonial cleansing. This period was deemed highly unlucky.

Allied deities were the very old pair of fire-gods, Cacus and Caca, probably belonging to the Palatine settlement, and the later Fornax, spirit of the baker's oven (hence Vesta's association with the ass, which turns the mill; bakers in early Rome were also millers).

Frazer, *Golden Bough*, ii., p. 195 ff.; H. J. Rose, *Primitive Culture in Italy*, p. 81 ff., and in *Mnemosyne* (1925), p. 410 ff. (H. J. R.)

VESTERÅS or WESTERÅS, a town and bishop's see of Sweden, capital of the district (*län*) of Vestmanland, on a northern bay of Lake Mälar, 60 m. N.W. by W. of Stockholm by rail. Pop. (1928), 29,160. The original name of the town was Vestra Aros ("western mouth"), in distinction from Östra Aros, the former name of Uppsala. Several national diets were held in Vesterås, the most notable being those of 1527, when Gustavus Vasa formally introduced the Reformation into Sweden, and 1544, when he had the Swedish throne declared hereditary in his family. Its Gothic cathedral, rebuilt by Birger Jarl on an earlier site, and consecrated in 1271, was restored in 1850–60, and again in 1896–98. The episcopal library contains the valuable collection of books which Oxenstjerna, the chancellor of Gustavus Adolphus, brought away from Mainz near the end of the Thirty Years' War. A castle overlooking the town was captured by Gustavus Vasa and rebuilt by him, and again in the 17th century, and remains the seat of the provincial Government.

VESTINI, an ancient Sabine tribe which occupied the eastern and northern bank of the Aternus in central Italy. It entered into the Roman alliance, retaining its own independence, in 304 B.C., and issuing coins of its own in the following century. A northerly section round Amiternum near the passes into Sabine country probably received the Caerite franchise soon after. The local dialect, which belongs to the north Oscan group, survived certainly to the middle of the 2nd century B.C. (*see* the inscriptions cited below) and probably until the Social War. The oldest Latin inscriptions of the district are *C.I.L.* ix. 3,521, from Furfo with Sullan alphabet, and 3,574, which cannot be earlier than 100 B.C. (*see* LATIN LANGUAGE). The Latin first spoken by the Vestini was not that of Rome, but that of their neighbours the Marsi and Aequi (*qq.v.*). The inscription of Scoppito shows that at the time at which it was written the upper Aternus valley must be counted Vestine, not Sabine, in point of dialect.

VESTMENTS, ceremonial garments worn by priests and others in performing the offices of religion. Ecclesiastical vestments, to which this article is confined, are the special articles of costume worn by the officers of the Christian Church "at all times of their ministration," as distinct from the "clerical costume" worn in everyday life. Ecclesiastical vestments may be divided into two categories: (1) liturgical, (2) non-liturgical. Liturgical vestments are again divided, under the completed rules of the Catholic Church, into three classes: (1) Those worn only at the celebration of mass—chasuble, maniple, pontifical shoes and

gloves, *pallium;* (2) those never worn at mass, but at other liturgical functions—surplice and cope; (3) those used at both—alb, amice, stole, dalmatic, tunicle. Non-liturgical vestments are those —*e.g.*, cappa magna, rochet—which have no sacred character, have come into use from motives of convenience or as ensigns of dignity, and are worn at secular as well as ecclesiastical functions.

Origin of Ecclesiastical Vestments.—The liturgical vestments of the church are not, as was once supposed, borrowed from the sacerdotal ornaments of the Jewish ritual, but were developed out of the articles of dress worn by all and sundry under the Roman empire.

Thus in the 37th of the so-called "canons of Hippolytus" we read: "As often as the bishops would partake of the Mysteries, the presbyters and deacons shall gather round him clad in white, quite particularly clean clothes, more beautiful than those of the rest of the people."

When, in the year 258, St. Cyprian was led to martyrdom, he wore (*see* Braun, *Die liturgische Gewandung*, 1907, p. 65) an under tunic (*linea*), an upper tunic (*tunica dalmatica*) and mantle (*lacerna, byrrus*). This was the ordinary type of the civil costume of the time. The *tunica*, a loose sack-like tunic with a hole for the head, was the innermost garment worn by all classes of Roman citizens under the republic and empire. The tunica was originally of white wool, but in the 3rd century it began to be made of linen, and from the 4th century was always of linen. About the 6th century the long *tunica alba* (white tunic) went out of fashion in civil life, but it was retained in the services of the Church and developed into the various forms of the liturgical alb (*q.v.*) and surplice (*q.v.*). The *tunica dalmatica* was a long, sleeved upper tunic, originating, as its name implies, in Dalmatia, and first becoming fashionable at Rome in the 2nd century; it is the origin of the liturgical dalmatic and tunicle (*see* DALMATIC). Another over-dress of the Romans was the *paenula*, a cloak akin to the *poncho* of the modern Spaniards and Spanish Americans, *i.e.*, a large piece of stuff with a hole for the head to go through, hanging in ample folds round the body. This was originally worn only by slaves, soldiers and other people of low degree; in the 3rd century, however, it was adopted by fashionable people as a convenient riding or travelling cloak; and finally, by the sumptuary law decreed by the emperor Theodosius in 382, it was prescribed as the proper everyday dress of senators, instead of the military chlamys, the toga being reserved for state occasions. This was the origin of the principal liturgical vestment, the chasuble (*q.v.*).

FROM BRAUN, "DIE LITURGISCHE GEWANDUNG IM OCCIDENT UND ORIENT" (HERDEN, FREIBURG IM BREISGAU)

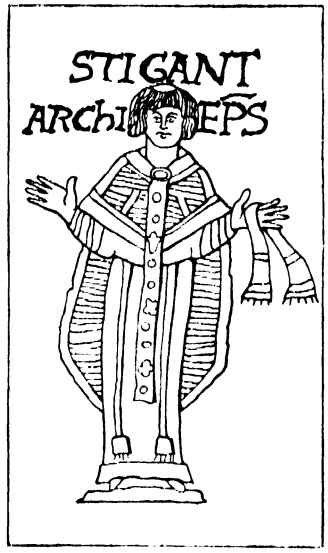
FIG. 1.—VESTMENTS OF POPE HONORIUS (D. 638), FROM A MOSAIC IN S. AGNESE IN ROME

As late as the 6th century these garments were common both to the clergy and laity, and, so far as their character was concerned, were used both in the liturgy and in everyday life. Meanwhile, however, a certain development had taken place. By the 4th century the garments worn at liturgical functions had been separated from those in ordinary use, though still identical in form. It is in the 4th century, too, that the first distinctive vestment makes its appearance, the *omophorion* worn by all bishops in the East; in the 5th century we find this in use at Rome under the name of *pallium* (*q.v.*), as the distinctive ornament of the pope (*see* fig. 1). About the same time the *orarium*, or stole (*q.v.*), becomes fixed in liturgical use. The main development and definition of the ecclesiastical vestments, however, took place between the 6th and 9th centuries. The secular fashions altered with changes of taste; but the Church retained the dress with the other traditions of the Roman empire. At Rome, especially, where the popes had succeeded to a share of the power and pretensions of the Caesars of the West, the accumulation of ecclesiastical vestments symbolized a very special dignity: in the second quarter of the 9th century the pope, when fully vested, wore a *camisia* girdled (*see* ROCHET), an alb (*linea*) girdled, an amice (*anagolaium*), a tunicle (*dalmatica minor*), a dalmatic (*dalmatica major*), stole (*orarium*), chasuble (*planeta*) and pallium. With the exception of the pallium, this was also the costume of the Roman deacons. By this time, moreover, the liturgical character of the vestments was so completely established that they were no longer worn instead of, but over, the ordinary dress.

Hitherto the example of the Roman Church had exercised no exclusive determining influence on ritual development even in the West. The popes had, from time to time, sent the pallium or the dalmatic—specifically Roman vestments—as gifts of honour to various distinguished prelates; Britain, converted by a Roman mission, had adopted the Roman use, and English missionaries had carried this into the newly Christianized parts of Germany; but the great Churches of Spain and Gaul preserved their own traditions in vestments as in other matters. From the 9th century onwards, however, after the revival of the Roman empire by Charlemagne, this was changed; everywhere in the West the Roman use ousted the regional uses.

The process of assimilation, however, was by no means one-sided. If Spain and Gaul borrowed from Rome, they also exercised a reciprocal influence on the Roman use; it is interesting to note, in this connection, that of the names of the liturgical vestments a very large proportion are not of Roman origin, and that the non-Roman names tended to supersede the Roman in Rome itself. Apart from the archiepiscopal pallium, the Churches of Spain and Gaul had need to borrow from Rome only the dalmatic, maniple and liturgical shoes.

The period between the 9th and the 13th centuries is that of the final development of the liturgical vestments in the West. In the 9th century appeared the pontifical gloves; in the 10th, the mitre; in the 11th, the use of liturgical shoes and stockings was reserved for cardinals and bishops. By the 12th century, mitre and gloves were worn by all bishops.



In an age when, with the feudal organization of society, even everyday costume was becoming a uniform, symbolizing the exact status of the wearer, it was natural that in the Church the official vestments should undergo a similar process. With this process, which was practically completed in the 11th century, doctrinal developments had little or nothing to do, though from the 9th century onwards liturgiologists were busy expounding the mystic symbolism of garments which hitherto had for the most part no symbolism whatever. Yet in view of later controversies, the changes made during this period, notably in the vestments connected with the mass, are not without significance. Hitherto the chasuble had been worn indifferently by all ministers at the eucharist, even by the acolytes; it had been worn also at processions and other non-liturgical functions; it was now exalted into the mass vestment *par excellence*. New vestments took the place, on less solemn occasions, of those hallowed by association with the holy sacrifice; thus the processional cope (*q.v.*) appeared in the 11th century and the surplice (*q.v.*) in the 12th. A change, too, came over the general character of vestments. Up to the 9th century these had been very plain; what splendour they had was due to their material and the ample folds of their draperies. But from this time onwards they tend to become more and more elaborately decorated with embroidery and jeweller's work (see, *e.g.*, the articles CHASUBLE and COPE).

Very significant, too, is the parting of the ways in the development of liturgical vestments in the East and West. During the first centuries both branches of the Church had used vestments substantially the same, developed from common originals; the alb, chasuble, stole and pallium were the equivalents of the *stichárion, phenailion, orárion* and *omophorion*. While, however, between the 9th and 13th centuries, the Western Church was adding largely to her store of vestments, that of the East increased her list by but three, the *encheirion, epimanikia* (*see* MANIPLE) and the *sakkos* (*see* DALMATIC).

In the Western Church, though considerable alterations continued to be made in the shape and decoration of the liturgical vestments, and in this respect various Churches developed different traditions, the definition of their use was established by the close of the 13th century and still continues in force. Before discussing the changes made in the Reformed Churches, due to the doctrinal developments of the 16th century, we may therefore give here a list of the vestments now worn by the various orders of clergy in the Roman Catholic Church and the Oriental Churches.

Roman Catholic Church.—As the sacrifice of the mass is the central mystery of the Catholic faith, the vestments worn by the priest when celebrating mass are the most important. The cassock (*q.v.*), which must always be worn under the vestments, is not itself a liturgical garment. Over this the priest, robing for mass, puts on the amice, alb, girdle (*cingulum*), maniple, stole and chasuble. Taking the other orders downwards: deacons wear amice, alb, girdle, maniple, stole and dalmatic; subdeacons, amice, alb, girdle, maniple and tunicle; the vestment proper to the minor orders, formerly the alb, is now the surplice or cotta. (The stole and maniple alone are symbolical of order, *i.e.*, of the relation to the sacrifice of the mass.) Bishops, as belonging to the order of priesthood with completed powers, wear the same vestments as the priests, with the addition of the pectoral cross, the pontifical gloves and ring; liturgical sandals and stockings; a tunicle and dalmatic worn over the stole and under the chasuble, and the mitre (*see* fig. 3). Archbishops, on solemn occasions, wear the pallium over the chasuble (*see* fig. 2). Bishops also carry a pastoral staff (*q.v.*) as a symbol of their pastoral office. Finally, the pope, when celebrating mass, wears the same vestments as an ordinary bishop, with addition of the subcinctorium (*see* ALB), and *orale* or *fanone* (*see* AMICE). It should be noted that the *liturgical* head-dress of the pope is the mitre, not the tiara, which is the symbol of his supreme office and jurisdiction (*see* TIARA).

Of the liturgical vestments not immediately or exclusively associated with the sacrifice of the mass the most conspicuous are the cope and surplice. The biretta, too, though not in its origin or in some of its uses a liturgical vestment, has developed a distinctly liturgical character (*see* BIRETTA). Besides the strictly liturgical vestments there are also numerous articles of costume worn at choir services, in processions, or on ceremonial occasions in everyday life, which have no sacral character; such are the almuce (*q.v.*), the *cappa* and *mozzetta* (*see* COPE), the rochet (*q.v.*), the *pileolus*, a skull-cap, worn also sometimes under mitre and tiara. These are generally ensigns of dignity; their form and use vary in different churches, and they often represent special privileges conferred by the popes, *e.g.*, the *cappa* of the Lateran basilica worn by the canons of Westminster cathedral, or the almuce worn, by concession of Pope Pius IX., by the members of the Sistine choir.

FROM FOWKE, "BAYEUX TAPESTRY" (BELL & SONS)

FIG. 2.—VESTMENTS OF STIGAND, ARCHBISHOP OF CANTERBURY (1052–1070); FROM THE BAYEUX TAPESTRY

Oriental Churches.—As already stated, the vestments of the great historical Churches of the East are derived from the same Graeco-Roman originals as those of the West, but in contradistinction to the latter they have remained practically stereotyped, both in character and number, for a thousand years; in the East, however, even more than in the West the tendency to gorgeous ornamentation has prevailed.

An Orthodox bishop, vested for the holy liturgy, wears over his cassock: (1) the *sticharion* or alb (*q.v.*); (2) the *epitrachelion* or stole (*q.v.*); (3) the *zone*, a narrow stuff girdle clasped behind, which holds together the two vestments above named; (4) the *epimanikia*, liturgical cuffs, corresponding, possibly, to the pontifical gloves of the West; (5) the *epigonation*, a stiff lozenge-shaped piece of stuff hanging at the right side by a piece of riband from the girdle or attached to the *sakkos*, the equivalent of the Western maniple (*q.v.*); (6) the *sakkos*, like the Western dalmatic (*q.v.*), worn instead of the *phainolion*, or chasuble; (7) the *omophorion*, the equivalent of the Western pallium (*q.v.*). Besides these, the bishop wears a pectoral cross (*engkolpion*) and a medal containing a relic (*panagia*). He also has a mitre (*q.v.*), and carries a crozier (*dikanikion*), a rather short staff ending in two curved branches with serpents' heads, with a cross between them.

FROM BRAUN, "DIE LITURGISCHE GEWANDUNG IM OCCIDENT UND ORIENT" (HERDER, FREIBURG IM BREISGAU)

FIG. 3.—VESTMENTS OF THE MONUMENTAL FIGURE OF BISHOP JOHANNES OF LÜBECK (D. 1350) IN LÜBECK CATHEDRAL, GERMANY

The vestments of a priest are the sticharion, epitrachelion, girdle, epimanikia and phainolion (*see* CHASUBLE). He wears all these vestments only at the celebration of the eucharist and on other very solemn occasions; at other ministrations he wears only the epitrachelion and phainolion over his cassock. A dignitary in priest's orders is distinguished by wearing the epigonation; and in Russia the use of the mitre is sometimes conceded to distinguished priests by the tsar. The deacon wears the sticharion, without a girdle, the epimanikia, and the orarion (*see* STOLE) hanging over his left shoulder. The lesser orders wear a shorter sticharion and an orarion wound round it.

On less solemn occasions bishops wear the *mandyas*, a cope-like garment fastened at the lower corners as well as at the neck, and the *kalimaukion*, a tall, brimless hat, with a veil hanging down behind, and in place of the *dikanikion* they carry a short staff with an ivory cross-piece.

The Liturgical Colours.—In another respect the vestments of the Eastern differ from those of the Western Church. In the East there is no sequence of liturgical colours; the vestments are usually white or red, and stiff with gold embroidery. In the West the custom, long universal, of marking the seasons of the ecclesiastical year and the more prominent fasts and festivals by the colour of the vestments of clergy and altar, dates, approximately, from the 12th century, certain rules being laid down by Pope Innocent III., *c.* 1200, which are still those of the Roman Church.

According to the rubric of the Roman Missal (*tit.* xviii.) the liturgical colours are five: white, red, green, violet, black. The following is a list of the occasions to which the various colours are appropriated:—

White.—Christmas to octave of Epiphany, Trinity Sunday, all festivals of Christ (except those of the Passion), of the Blessed Virgin, the Holy Angels and Confessors, holy virgins and women (not martyrs), nativity of St. John the Baptist, festivals of the chains of St. Peter and of his see (*cathedra Petri*), Conversion of St. Paul, All Saints, consecration of churches and altars, anniversary of election and coronation of popes, and of election and consecration of bishops. White is also worn during the octaves of these festivals, on ordinary days (for which no special colour is provided) between Easter and Whitsuntide, at certain special masses connected with the saints falling under the above category and at bridal masses. White is also the colour proper to sacramental processions, and generally to all devotions connected with the exposition of the Blessed Sacrament. At baptisms the priest wears a violet stole during the first part of the service, *i.e.*, the exorcization, then changes it for a white one. White is worn at the funerals of children.

Red.—Saturday before Whit Sunday, Whit Sunday and its

octave; all festivals in commemoration of the sufferings of Christ, *i.e.*, festival of the instruments of the Passion, of the Precious Blood, of the invention and elevation of the Cross; all festivals of apostles, except those above noted; festivals of martyrs; masses for a papal election; the Feast of the Holy Innocents, when it falls on a Sunday (violet if on a week-day), and its octave (always red). In England red vestments are worn at the mass (of the Holy Spirit) attended by the Roman Catholic judges and barristers at the opening of term, the so-called "Red Mass."

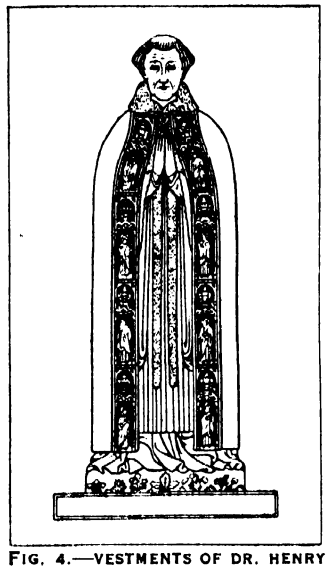


FIG. 4.—VESTMENTS OF DR. HENRY SEVER (D. 1471), FROM A BRASS IN THE CHAPEL OF MERTON COLLEGE, OXFORD, SHOWING SURPLICE, ALMUCE, AND COPE

Green.—From the octave of Epiphany to Septuagesima, and between Trinity and Advent, except festivals and their octaves and Ember days.

Violet.—Advent; the days between Septuagesima and Maundy Thursday; vigils that fall on fast days, and Ember days, except the vigil before Whit Sunday (red) and the Ember days in Whitsun week (red). Violet vestments are also worn on days of intercession, at votive masses of the Passion, at certain other masses of a pronouncedly intercessory and penitential character, at intercessory processions, at the blessing of candles on Candlemas Day, and at the blessing of the baptismal water. A violet stole is worn by the priest when giving absolution after confession, and when administering extreme unction.

Black.—Masses for the dead and funeral ceremonies of adults; the mass of the presanctified on Good Friday.

In the Anglican Church, where the liturgical colours have been revived, these generally follow the Roman use. Some churches, however, have adopted the colours of the use of Salisbury (Sarum), which was in force before the Reformation throughout the province of Canterbury.

Benediction of Vestments.—In the Roman Catholic Church the amice, alb, girdle, stole, maniple, chasuble must be solemnly blessed by the bishop or his delegate, the prayers and other forms to be observed being set forth in the *Pontificale* (*see* BENEDICTION). Other vestments—*e.g.*, dalmatic, tunicle, surplice—are sometimes blessed when used in connection with the sacrifice of the mass, but there is no definite rule on the subject.

Mystic Meaning of Vestments.—The origin of the vestments was in course of time forgotten, and they began to develop a symbolic meaning. The earliest record of any attempt to interpret this symbolism that we possess is, so far as the West is concerned, the short exposition in the *Explicatio Missae* of Germanus, bishop of Paris (d. 576), the earliest of any elaboration that of Hrabanus Maurus (d. 856). From the latter's time onward a host of liturgists took up the theme, arguing from the form, the material, the colour and the fashion of wearing the various garments to symbolical interpretations almost as numerous as the interpreters themselves. We cannot even outline here the process of selection by which the symbolic meanings now stereotyped in the Roman Pontifical were arrived at. They are now formulated in the words used by the bishop when, in ordaining to any office, he places the vestment on the ordinand with the appropriate words, *e.g.*, "Take the amice, which signifies discipline in speech," while other interpretations survive in the prayers offered by the priest when vesting, *e.g.*, with the amice, "Place on my head the helmet of salvation," etc.

Protestant Churches.—In the Protestant Churches the custom as to vestments differs widely, corresponding to a similar divergence in tradition and teaching. At the Reformation two tendencies became apparent. Luther and his followers regarded vestments as among the *adiaphora*, and in the Churches which afterwards came to be known as "Lutheran" many of the traditional vestments were retained. Calvin, on the other hand, laid stress on the principle of the utmost simplicity in public worship; at Geneva the traditional vestments were absolutely abolished, and the Genevan model was followed by the Calvinistic or "Reformed" Churches throughout Europe. The Church of England, in which the Lutheran and Calvinistic points of view struggled for the mastery, a struggle which resulted in a compromise, is separately dealt with below. At the present day the Lutheran Churches of Denmark and Scandinavia retain the use of alb and chasuble in the celebration of the eucharist (stole, amice, girdle and maniple were disused after the Reformation), and for bishops the cope and mitre. The surplice is not used, the ministers conducting the ordinary services and preaching in a black gown, of the 16th century type, with white bands or ruff. In Germany the Evangelical Church (outcome of a compromise between Lutherans and Reformed) has, in general, now discarded the old vestments. In isolated instances (*e.g.*, at Leipzig) the surplice is still worn; but the pastors now usually wear a barret cap, a black gown of the type worn by Luther himself, and white bands. In Prussia the superintendents now wear pectoral crosses (instituted by the emperor William II.). In the "Reformed" Churches the minister wears the black "Geneva" gown with bands. It is to be noted, however, that this use has been largely discontinued in the modern "Free" Churches. On the other hand, some of these have in recent times adopted the surplice, and in one at least (the "Irvingite" or Catholic Apostolic Church) the traditional Catholic vestments have been largely revived.

Anglican Church.—In the matter of the vestments the Reformation in England passed through several stages. Under Henry VIII. no alterations were made. In the first Prayer Book of Edward VI. (1549) the Lutheran example seems to have been followed: the priest at Holy Communion is directed to wear "a white alb plain with a vestment or cope," while the assisting priests or deacons are to wear "albs with tunicles." Elsewhere there are directions for the wearing of surplice and hood at choir services in cathedrals and collegiate churches, and bishops are directed to wear, besides a rochet, a surplice or alb, and a cope or vestment, with a pastoral staff borne either by themselves or their chaplains. Of the amice, girdle, maniple and stole there is no word; and, in view of the practice of the "Lutheran" Churches, it appears that these vestments were to be disused.

FIG. 5.—VESTMENTS OF CRANLEY, ARCHBISHOP OF DUBLIN (D. 1417), FROM A BRASS IN NEW COLLEGE CHAPEL, OXFORD, SHOWING MITRE, AMICE, CHASUBLE, MANIPLE, DALMATIC, TUNICLE, STOLE, ALB, GLOVES AND CALIGAE, AND WEARING THE PALLIUM OVER THE CHASUBLE

The intention of the framers of this book, among whom was Bishop Ridley, was to substitute the Holy Communion for the Mass considered as a sacrifice. It was soon found, however, that the conservative clergy took advantage of the retention of so much of the old liturgy to celebrate it as "a verie masse." To guard against this the second Prayer Book of Edward VI., in addition to changing the order of the prayer of consecration, prescribed as the sole vestment of the minister the surplice, which had never been associated with the sacrifice of the mass, but had been for many centuries the vestment proper to the administration of the sacraments (*see* SURPLICE). This book was, of course, suppressed during the reaction of Queen Mary's reign, but in 1559, after the accession of Elizabeth, parliament once more adopted it, and passed the Act of Uniformity, which made its use obligatory on all.

The Ornaments Rubric.—In the Prayer Book of 1559 no

explicit directions were given as to the vestments to be worn. It is probable that the queen, from motives of policy as well as personal tastes, wished to preserve as far as possible the outward forms of the "old religion." However this may be, the Act of Uniformity, prefixed to the new Prayer Book, ended with a section directing that the ornaments of the Church and of the ministers thereof were to be "retained and had in use" as they were "by authority of Parliament in the second year of the reign of King Edward VI., until other order shall be therein taken by the authority of the Queen's Majesty, with the advice of the Commissioners appointed and authorized under the Great Seal of England, or of the Metropolitan." The rubric in the Prayer Book itself, apparently inserted by the Privy Council without the authority of parliament, ran: ". . . the minister at the time of the Communion, and at other times of his administration, shall use etc. . . . according to the Act of Parliament at the beginning of this book." The wording of the "Ornaments rubric" in the Prayer Book as revised in 1662, and still in use, was taken directly from the last section of the Act of Uniformity.

FROM DRUITT, "COSTUME ON BRASSES" (MORING)

FIG. 6.—VESTMENTS OF ANGLICAN PRIEST IN CASSOCK, SURPLICE, AND NARROW BLACK SCARF, FROM A BRASS OF WILLIAM DYÉ (D. 1567) AT WESTERHAM, KENT

This ambiguous procedure lies at the root of the troubles which have since distracted the Church of England. The second year of Edward VI. is now admitted to mean the first Prayer Book, which authorized, not indeed all the Mass vestments, but at least the most conspicuous of them. Yet nothing is historically clearer than the fact that these vestments were not retained. If they continued anywhere in use after 1559, it was not for long.

Whatever the letter of the law under the rubric, the Protestant bishops and the commissioners made short work of such "popish stuff" as chasubles, albs and the like. As for copes, in some places they were ordered to be worn, and were worn at the Holy Communion, while elsewhere they were burned.

The difficulty seems to have been not to suppress the chasuble, of the use of which after 1559 not a single authoritative instance has been adduced, but to save the surplice, which the more zealous Puritans looked on with scarcely less disfavour. At last, in 1565, Queen Elizabeth determined to secure uniformity. The result was the issue in 1566 by the archbishop of the statutory *Advertisements,* which fixed the vestments of the clergy as follows: (1) In the ministration of the Holy Communion in cathedral and collegiate churches, the principal minister to wear a cope, with gospeller and epistoler agreeably; at all other prayers to be said at the Communion table, to use no copes but surplices; (2) the dean and prebendaries to wear surplice and hood; (3) every minister saying public prayers, or ministering the sacraments, to wear "a comely surplice with sleeves." For 300 years these directions (confirmed by the canons of 1603) governed the use of the Church of England in the matter of vestments, though the cope came to be worn only on occasions of high ceremony.

With the growth of the "Oxford" or "Tractarian" movement, from 1830 onward, there came a change. The revival of high sacramental doctrine and of the belief in the Sacrifice of the Mass (which was ingeniously distinguished from the "sacrifices of masses" denounced in the XXXIX. Articles) naturally led to a movement to revive the use of the vestments which symbolized these doctrines. Opposition was naturally aroused; the law was appealed to; and the judicial committee of the Privy Council (*Hebbert* v. *Purchas,* 1870, and *Ridsdale* v. *Clifton,* 1877) decided that the *Advertisements* of 1566 were the "other order" contemplated in Elizabeth's Act of Uniformity, and that from this time the cope and surplice were the only vestments legal in the Church of England. In the course of their judgment their lordships pointed out that the *Advertisements* had been accepted as authoritative by the canons of 1603 (canons 24 and 58), and argued convincingly that the revisers of the Prayer Book in 1662, in restoring the rubric of 1559, had no idea of legalizing any vestments other than those in customary use under the *Advertisements* and the canons.

This judgment was far from settling the question. The "ritualistic" clergy refused to obey it, on the ground that it was not delivered by a spiritual court; and, in the absence of any generally recognized authority, the clergy did what was right in their own eyes, until in place of the old ideal expressed in the Acts of Uniformity, there were almost as many "uses" as parishes, doctrine and the vestments which symbolized it varying through every shade from Rome to Geneva. Thirty years after the Ridsdale judgment the confusion had become so great that it was felt that something must be done to restore at least a semblance of unity, the dominant opinion being that this could best be done by sanctifying with some sort of authority the parochial uses which had grown up. To this end convocation appointed a subcommittee of five bishops to investigate the matter. Their report "On the Ornaments of the Church and its Ministers"—a learned and ingenious document—was presented in 1908. It concluded that under the Ornaments Rubric the vestments prescribed in the first Prayer Book of Edward VI. are permitted, if not enjoined.

FIG. 7.—VESTMENTS OF ARCHBISHOP OF GREEK ORTHODOX CHURCH IN FULL ROBES

This naturally gave a great impetus to the "Anglo-Catholic" movement, which was now favoured by many, if not most, of the bishops; but nothing could be done to give the revived practices legal validity so long as the Church continued to be effectively under the control of Parliament. The situation in this respect was altered by the so-called Enabling Act of 1919, which gave to the Church powers of self-government, measures passed by the Convocations and the newly established Church Assembly being subject only to the veto of parliament. Early in 1927 an alternative Prayer Book, drawn up by a committee of bishops and intended, among other things, to regularize practices of doubtful legality under the old book, was adopted by both Convocations and by the Church Assembly. The rubric in this alternative book (the old Prayer Book still being retained alongside of it) directs that the minister at the Holy Communion is to wear either a surplice with stole or scarf, or "an alb plain with a vestment or cope." The last direction, borrowed from the first Prayer Book of Edward VI., is not explained, and "an alb plain" therefore seems to mean without amice, maniple and girdle, the stole being admitted by implication. The alternative Prayer Book was submitted to Parliament in 1928 but was rejected by the House of Commons.

VESTRIS, LUCIA ELIZABETH (1797–1856), English actress, was born in London in Jan. 1797, the daughter of Gaetano Stefano Bartolozzi (1757–1821) and granddaughter of Francesco

Bartolozzi, the engraver. In 1813 she married Auguste Armand Vestris, who deserted her four years later. Madame Vestris had made her first appearance in Italian opera in the title-rôle of Peter Winter's *Il ratto di Proserpina* at the King's theatre in 1815. She had an immediate success in both London and Paris, where she played Camille to Talma's Horace in *Horace*. Her first hit in English was at Drury Lane in James Cobb's (1756–1818) *Siege of Belgrade* (1820). She was particularly a favourite in "breeches parts," like Cherubino in the *Marriage of Figaro*, and in *Don Giovanni*. In 1831 she became lessee of the Olympic theatre, and began the presentation of a series of burlesques and extravaganzas for which she made this house famous. She married Charles James Mathews (*q.v.*) in 1838, accompanying him to America and aiding him in his subsequent managerial ventures. She died in London on Aug. 8, 1856.

See C. E. Pearce, *Madame Vestris and her Times* (1923).

VESUVIUS, a volcano rising from the eastern margin of the Bay of Naples in Italy, about 7 m. E.S.E. of Naples. The height of the mountain varies from time to time within limits of several hundred feet, but averages about 4,000 ft. above sea-level (in June 1900, 4,275 ft., but after the eruption of 1906 3,668 ft.). Vesuvius consists of two distinct portions. On the northern side a lofty semicircular cliff, reaching a height of 3,714 ft., half encircles the present active cone, and descends in long slopes to the plains. This precipice, Monte Somma, forms the wall of a vastly greater prehistoric crater.

At the beginning of the Christian era, and for many previous centuries, no eruption had been known. Strabo, however, detected the probable volcanic origin of the cone and drew attention to its fire-eaten rocks. The sides of the mountain were richly cultivated, as they are still, the vineyards being of extraordinary fertility. Pompeian wine jars are frequently marked with the name *Vesuvinum* (*vinum*). (The wine is now known as *Lacrima Christi.*) On the barren summit lay a wide flat depression, walled by rugged rock festooned with wild vines. The present crater-wall of Monte Somma is doubtless a relic of that time. It was in this lofty rock-girt hollow that the gladiator Spartacus was besieged by the praetor Claudius Pulcher (73 B.C.): he escaped by twisting ropes of vine branches and descending through unguarded fissures in the crater-rim. A painting discovered when excavating in Pompeii in 1879 represents Vesuvius before the eruption (*Notizie degli scavi,* 1880, pl. vii.).

After centuries of quiescence the volcanic energy began again to manifest itself in a succession of earthquakes, which spread alarm through Campania. For some sixteen years after 63 these convulsions did much damage to the surrounding towns. On Aug. 24, 79, the earthquakes, which had been growing more violent, culminated in a tremendous explosion of Vesuvius. A contemporary account of this event has been preserved in two letters of the younger Pliny (Epist. vi. 16, 20) to the historian Tacitus. He was staying at Misenum with his uncle, the elder Pliny, who was in command of the fleet. The latter set out on the afternoon of the 24th to attempt to rescue people at Herculaneum, but came too late, and went to Stabiae, where he spent the night, and died the following morning, suffocated by the poisonous fumes. Three towns are known to have been destroyed—Herculaneum at the western base of the volcano, Pompeii on the south-east side, and Stabiae, which was situated farther south on the site of the modern Castellamare.

For nearly fifteen hundred years after the catastrophe of 79 Vesuvius remained in a condition of less activity. Occasional eruptions are mentioned, in A.D. 202, 472, 512, 685, 993, 1036, 1049, 1139. At length, after a series of earthquakes lasting for six months and gradually increasing in violence, the volcano burst into renewed paroxysmal activity on Dec. 16, 1631. Though the inhabitants had been warned by the earlier convulsions of the mountain, so swiftly did destruction come upon them that 18,000 are said to have lost their lives.

Since this great convulsion, which emptied the crater, Vesuvius has never again relapsed into a condition of total quiescence. At intervals, varying from a few weeks or months to a few years, it has broken out into eruption, sometimes emitting only steam, dust and scoriae, but frequently also streams of lava. The years 1766–67, 1779, 1794, 1822, 1872, 1906 and 1929 were marked by special activity. The extensive eruption of 1906 completely altered the conformation and aspect of the cone, considerably reducing its height.

The modern cone of the mountain has been built up by successive discharges of lava and fragmentary materials round a vent of eruption, which lies a little south of the centre of the prehistoric crater. The southern segment of the ancient cone, answering to the semicircular wall of Somma on the north side, has been almost concealed, but is still traceable among the younger accumulations. The numerous deep ravines which indented the sides of the prehistoric volcano, and still form a marked feature on the outer slopes of Somma, have on the south side served as channels to guide the currents of lava from the younger cone. On one of the ridges between these radiating valleys an observatory for watching the progress of the volcano was established by the Neapolitan government (1844), and is now a national institution. A continuous record of each phase in the volcanic changes has been taken, and some progress has been made in the study of the phenomena of Vesuvius, and in prognosticating the occurrence and probable intensity of eruptions. The foot of the cone is reached from Naples by electric railway, and thence a wire-rope railway (opened in 1880) carries visitors to within 150 yd. of the mouth of the crater.

VETCH, in botany, the English name for *Vicia sativa,* also known as tares, a leguminous annual herb with trailing or climbing stems, compound leaves with five or six pairs of leaflets, reddish-purple flowers borne singly or in pairs in the leaf-axis, and a silky pod containing four to ten smooth seeds. The wild form, sometimes regarded as a distinct species, *V. angustifolia,* is common in dry soils. There are two races of the cultivated vetch, winter and spring vetches: the former, a hardy form, capable of enduring frost, has smoother, more cylindrical pods with smaller seeds than the summer variety, and gives less bulk of stem and leaves. The spring vetch is a more delicate plant and grows more rapidly and luxuriantly than the winter variety.

The name vetch is applied to other species of the genus *Vicia. Vicia orobus,* bitter vetch, and *V. sylvatica,* wood vetch, are British plants. Another British plant, *Hippocrepis,* is known as horseshoe vetch from the fact of its pod breaking into several horseshoe-shaped joints. *Anthyllis vulneraria* is kidney-vetch, a herb with heads of usually yellow flowers, found on dry banks. *Astragalus,* another genus of Leguminosae, is known as milk-vetch; species of *Coronilla* are known as crown vetch.

Vetches are a very valuable forage crop indigenous to Great Britain. Vetches are well adapted for poor soils. They are generally used in combination with grass and clover, beginning with the first cutting of the latter in May, taking the winter vetches in June, recurring to the Italian rye grass or clover as the second cutting is ready, and afterwards bringing the spring vetches into use. Each crop of vetch can thus be utilized when in its best condition for cattle food. (X.)

Cultivation in the United States.—Vetches are most extensively grown in the Pacific Coast area in the States of Washington, Oregon and California, and in the Great Lakes area in the States of Michigan, Indiana, Ohio and New York. In the latter region hairy vetch (*V. villosa*) is used almost exclusively, while in the former region common vetch (*V. sativa*) is much more frequently planted. Hairy vetch is chiefly grown for green manure and seed crop. Common vetch, while widely grown as a soil-improving crop, is used in western Oregon and Washington for

pasturage, silage, hay, green fodder and seed crop. In general, the cultural practices with vetches are the same as in European countries. Like other legumes, vetches require the presence of certain symbiotic bacteria for their successful development; in planting vetch on lands for the first time such bacteria must be supplied by artificial inoculation.

Besides the hairy and the common vetch, several other species are grown to a limited extent, as the Hungarian vetch (*V. pannonica*) and the purple vetch (*V. atropurpurea*) in the Pacific States, and the monantha vetch (*V. monantha*) in the Gulf States.

(R. McKe.)

CULTIVATION AND TRADE

Vetches have long been esteemed as a supplementary green food for summer feeding, but in recent years they have been extensively cultivated also for the purposes of ensilage. Although a certain proportion of the vetch acreage must be cultivated for seed production, the crop is not commonly grown for its grain, but is generally cut in the flowering or early-seeding stage for the purposes first mentioned. Sometimes, however, vetches are grown in association with rye for early spring grazing—though earliness of growth in spring is not one of the special features of the vetch plant. Grown in association with oats they form a useful mixture for silage, for conversion into hay, or for green fodder.

There are two varieties of the common vetch (*Vicia sativa*), viz., the winter and the summer sorts. The botanical distinctions between the two varieties are not very pronounced, and in practice greater reliance must be placed on the parentage of the seed than on its name. When winter vetches are required, it is important to obtain seed from a crop that had been sown in the autumn.

Vetches are adapted for a very wide range of soils, but yield the greatest bulk of forage on land of the heavier and more moist class. The crop is usually grown without yard manure, but where this is available the vetch can make good use of it. In the absence of dung, a complete mixture of artificial manures should be given where the soil is in poor heart.

Even when intended for seed production, vetches are commonly grown in association with another crop that will afford mechanical support. For ensilage, typical mixtures for autumn sowing are two bushels of tares and ½ bushel of rye per acre; and two bushels of tares, ½ bushel of beans and ½ bushel of winter oats. These are for light and heavy land respectively. On rich land, however, lighter seedings of tares are required to avoid lodging, the difference being made up by increased quantities of beans and oats.

The vetches grown in Great Britain are put to a variety of uses. About 15% of the area is cut for hay, about 60% is cut for green fodder or silage, and about 25% is harvested ripe for the seed. A certain amount of green fodder and hay is sold to horse and cow owners in towns, but this trade declined very sharply with the reduction in the number of horses and of town dairies, and is now very small. Of the seed, only about 5,000 tons per annum are placed on the market, 70% of the produce being used for seed purposes or for feeding to stock on farms. That sold is usually bought for poultry and pigeon mixtures. Imports of vetch seed averaged only 25,000 tons in the five years 1922 to 1926, the bulk coming from the Baltic.

VETERANS' BUREAU: *see* Pensions in United States.

VETERINARY SCIENCE, the branch of knowledge that deals with the anatomy of domesticated animals, their physiology and racial characteristics, their breeding, feeding and hygienic management; the pathology and treatment of their diseases and injuries; the improvement of stock; their relations to man with regard to inter-communicable maladies and to his use of their flesh and products. Here the subject is considered in relation to medicine; other aspects are treated under special headings. (*See* Horse, Dog, etc.; Anthrax, Canine Distemper, Glanders, etc.; Slaughter-House and Abattoirs; and the comparative anatomy sections of separate anatomical articles.)

History.—The veterinary art in its modern development dates from the establishment of the veterinary school of Lyons in 1761. Schools were established in London in 1791; Edinburgh, 1823; Glasgow, 1863; Dublin, 1900; and Liverpool 1904 (transfer of a second Edinburgh school founded in 1873).

The profession was first organized in Great Britain by the foundation in 1844 of the Royal College of Veterinary Surgeons. This body regulates the examinations of students who must be trained in an affiliated veterinary college, appoints examiners, and admits as members of the college all who pass the qualifying examinations. There is thus only one portal into the veterinary profession. The Royal college keeps the statutory register of veterinary surgeons, has power to remove the names of members convicted of misdemeanours or of conduct disgraceful in a professional respect, and to prosecute unregistered persons who use a title stating that they are specially qualified to practise (Veterinary Surgeons Act, 1881). The recognized course of instruction covers a period of four years after the passing of an approved examination in general education, and leads to the diploma of M.R.C.V.S. Possession of this diploma is essential for commissioned rank in the Royal Army Veterinary Corps and for appointment as government veterinary officers in Great Britain and in the Dominions.

The Royal college also grants the postgraduate diploma of fellow, after presentation of a thesis of sufficient merit and the passing of a special examination. The college diploma in veterinary state medicine is awarded after nine months' postgraduate study in epizootiology, veterinary bacteriology, and protozoology, veterinary hygiene and toxicology, chemistry, meat inspection, dairy and milk inspection, administration and reporting. The universities of London, Edinburgh and Liverpool grant degrees in veterinary science (bachelor, master and doctor); the course is usually taken with that for the qualifying diploma but occupies five years. The degree in itself does not confer a licence to practise or entitle to registration. Liverpool university grants a postgraduate diploma in veterinary hygiene, and Manchester university a diploma in veterinary State medicine.

The veterinarian is in Great Britain legally debarred from treating certain diseases, *e.g.*, pleuro-pneumonia of cattle, rinderpest, glanders, epizootic lymphangitis, sheep-pox, rabies and foot and mouth disease. The Diseases of Animals Acts, 1894–1925, and the orders made thereunder provide for notification of the above-named diseases.

The Orders also provide for the notification of anthrax, parasitic mange of horses, sheep-scab, swine fever and certain forms of tuberculosis. Diagnosis of suspected disease by veterinary inspectors is followed by segregation, and destruction of diseased and in-contact animals where necessary with suitable compensation. Many markets and farms, and all ports, are systematically inspected and all importation of animals controlled. The Ministry of Agriculture and Fisheries has a staff of veterinary inspectors for this work and for the investigation of other animal diseases.

Local authorities in Great Britain and Ireland employ veterinary officers, either whole-time or part-time, for meat and milk inspection and to carry out the statutory duties of the authority for the eradication of contagious disease.

Research institutes have been established in London, Cambridge, Edinburgh, Weybridge and elsewhere, for the investigation of animal diseases and for the preparation of vaccines and sera for their prevention or treatment. Similar institutes have been created in many of the Dominions and Colonies.

In the United States courses leading to the degree of Doctor of Veterinary Science require three years and in the best colleges four years, the requirements for admission being a high-school education or its equivalent. Most of the State Universities have veterinary colleges in connection with their schools of agriculture and some of them give a six-year combined course leading to degrees in both agriculture and veterinary medicine. The American Veterinary Medical Association holds a place comparable to that of the Royal College of Veterinary Surgeons in Great Britain and exercises an influence on the setting of standards in the profession. Practitioners must be graduates of an acceptable school to gain admission. Besides the demand for private practice in rural localities, especially in connection with the growing dairy industry, the Bureau of Animal Industries, U.S. Dept. of Agri., employs

about a thousand veterinarians as meat inspectors, quarantine agents, and in extension work. The Veterinary Corps is a division of the Medical Department of the Army. Veterinary graduates are also in demand as State Veterinarians, as teachers and government research workers.

DISEASES OF DOMESTICATED ANIMALS

Reference is made here only to some of the more important disorders other than those described in separate articles which treat of ACTINOMYCOSIS, ANTHRAX, ABORTION, CANINE DISTEMPER, FOOT AND MOUTH DISEASE, GLANDERS, PLEURO-PNEUMONIA, RABIES, RINDERPEST, SWINE FEVER. In the treatment of animal patients the main object is to place them in those conditions which allow nature to operate most freely in restoring health. Fresh air, cleanliness, quiet and comfort, should be secured as far as possible.

The Horse.—*Epizootic Lymphangitis* is a chronic contagious disease, characterized by inflammation of the superficial lymphatic vessels and regional lymphatic glands. Nodular swellings appear which soften and discharge a creamy pus, with formation of ulcers. The eruptions usually appear on the limbs but may occur elsewhere, and are caused by the cryptococcus of Rivolta. Inoculation probably occurs through a wound, and lesions slowly appear. Affected animals are destroyed; they do not react to mallein, and the disease is thus distinguished from glanders.

Strangles is an acute contagious disease in which there is inflammation of the mucous membrane of the upper air passages and suppuration of lymphatic glands, usually the submaxillary, but other glands may be involved. An organism, *streptococcus equi,* is always present in the nasal discharge and in the abscess cavities, and is the probable cause, but a filterable virus has been suggested as the primary causative factor. Formerly common amongst young horses, it is becoming a rare disease under modern conditions. There is fever, catarrh, diminished appetite, languor and sore-throat; the suppurating glands become swollen and painful, and then soften and discharge pus. Recovery usually follows and immunity is acquired. Irregular or atypical forms of the disease occur, and are more dangerous. Infection takes place by inhalation and ingestion and also by inoculation or wound infection, with involvement of the associated lymph glands so that any part of the body may be affected. Widespread abscess formation is sometimes seen, due to pyaemic infection of the blood stream.

Horse-pox (*variola equina*), a rare and benign disease, spreads like cowpox, by contact, and may be transmitted to man. Lesions appear on the skin, in the hollows of the heels, on the back of the limbs, and on mucous membranes, mouth, nose, etc. Isolation, with strict cleanliness, for three weeks is advisable.

Cattle.—*Black-quarter* or *Blackleg* is a specific infection of young cattle, the causal organism being *B. chauveii.* Large crepitant swellings develop in the quarter or other parts; there is high fever, with lameness, and later, marked depression, and death occurs within two days. Immunity can, however, be conferred by vaccination with blackleg aggressin, and the disease can thus be controlled.

Mammitis, or *Garget,* of which there are acute and chronic forms, is due to a streptococcus transmitted usually in the process of milking. In acute cases the udder becomes swollen, hot and painful; in others the course is gradual, with little constitutional disturbance, the incubation period lasting for months. The milk may be scarcely altered or greatly changed and offensive. Tuberculous mastitis is of great importance and is usually chronic. Prevention depends on immediate isolation of affected animals, careful inspection, and cleanliness in housing and milking.

Milk Fever.—An intoxication associated with lactation most frequently met with in recently calved high-grade cows, but the goat, sow, bitch, mare and ewe are also susceptible. Symptoms vary widely, but usually involve the nervous system, causing excitement, spasms, paralysis, coma, and there is often marked disturbance of respiration, circulation and digestion. By inflation of the udder with filtered air or oxygen, as introduced by Schmidt of Kolding, Denmark, the mortality in this once fatal disease has been brought very low. Goats, ewes and mares respond to this treatment equally well.

Jöhne's Disease.—A chronic specific enteritis of cattle, caused by the growth in the intestinal mucous membrane and mesenteric glands of a bacillus discovered by Jöhne. It produces thickening of the bowel and interferes with food absorption; there is diarrhoea and extreme wasting. The course is long, sometimes years, and in such cases the animals are "carriers." Infection is by food contaminated with infected excreta. Early diagnosis is difficult. Suspected animals should be slaughtered; no treatment is effectual in severe cases. Some animals improve, put on weight, and again relapse. Isolation is important.

Cowpox (*variola vaccinia*), is a mild, contagious, eruptive disease of the udder and teats; the eruption at its height, when not altered by attempts at milking, shows a depressed centre, a raised silvery edge, containing lymph, and outside this a pink areola. It is transmissible to man, and affords protection against smallpox. (*See* VACCINATION.) In cows it requires little treatment.

Sheep-pox (*variola ovina*) is the most serious of all the variola of animals. It is highly infectious, and benign and malignant forms are met with. It occurs in France and southern and eastern European countries, but not in America or Australia. It is unlikely to appear in Great Britain. The virus is ultra-visible, and very resistant.

Foot-rot, a specific infectious disease of the feet in sheep, is said to be caused by the bacillus of necrosis, but this is probably a secondary invader. It is a soil disease, rare in hilly or light lands, but common on deep soils. Lameness may be severe, tissue changes marked, and the hoofs deformed. Arsenical footbaths are useful for mass treatment. Infected animals should not be introduced to sound flocks.

Tuberculosis.—An inoculable and infectious disease caused by the bacillus of Koch, of which there are three types, human, bovine and avian. No domestic animal is completely immune, but cattle, pigs and poultry are chiefly affected. In cattle, grape-like masses form in the chest and abdominal cavity, the lymphatic glands become enlarged and caseous, and diseased centres appear in the substance of the organs. The symptoms vary greatly according to the organs attacked. Cattle in apparent health may on post-mortem show extensive invasion. The tuberculin test is efficient in proving the existence of infection, but not its degree, and emaciated, heavily-affected animals may fail to react. Congenital tuberculosis is rare, post-natal infection being the rule. This fact induced Bang to advocate isolation of reactors, with pasteurization of milk, for eliminating tuberculosis from herds. Calmette has introduced a live vaccine (B.C.G.) so modified that although it confers immunity from natural infection it is not pathogenic for animals or men. "Open tuberculosis" is a term applied to advanced cases of the disease affecting the lungs, bowels, womb, and udder, or otherwise discharging bacilli and therefore dangerous, and by the Tuberculosis Order all such cases must be notified. In pigs the glands of the throat and the bones are often diseased, and in the latter case the meat is condemned. The bovine bacillus, found in meat and particularly in milk, is the cause of considerable disease, especially in children.

Poultry Diseases.—The diseases here mentioned are all highly contagious and fatal. In all cases segregation, and rigid disinfection of runs, incubators and fittings are essential.

Bacillary White Diarrhoea is the most important disease of fowls in this country, and responsible for more losses than all other diseases combined. It runs an acute course in chicks and a chronic course in adults. Chicks which survive an outbreak may become "carriers," and on reaching maturity produce eggs containing the causal agent, *B. pullorum.* The disease is mainly introduced by infected eggs, day-old chicks, or adult "carrier" fowls. "Carriers" can be detected by the agglutination test.

Coccidiosis, next in importance, is caused by the protozoan *Eimeria avium,* and attacks chicks from two to eight weeks old. The mortality varies from 20 to 90%, depending on their age.

Fowl Pox, a contagious disease due to a filter-passing virus, is characterized by eruptive lesions on the skin or its appendages, by diphtheritic membranes in the mouth, or by an oculo-nasal dis-

charge. There may be present only one of these lesions, or a combination of them, in the same bird.

Fowl Typhoid, enzootic in Wales and the bordering counties, and the cause of heavy annual losses, is a contagious septicaemia, the symptoms being pallidity of comb and a characteristic greenish yellow diarrhoea. The incubation period is about six days and death may occur within 16 days.

Gapes, due to worms in the wind-pipe causing the bird to gasp for breath, affects mainly young chicks. Gape-worm eggs passed in the bird's faeces contain larvae after ten days' time, and may hatch; infestation is caused by swallowing free larvae or eggs containing larvae. Prevention is by isolation. Turkeys frequently carry the parasite, and should not run with chickens.

Fowl Cholera, very rare in Great Britain, is caused by *B. avisepticus.* It is characterized by profuse diarrhoea and is highly fatal. The intestinal mucous membrane usually shows acute inflammation and small haemorrhages are frequently present in the heart.

Fowl Plague, due to a filter-passing virus, has an incubation period of 24 to 48 hours; treatment is useless.

Parasitology.—The small intestines of colts are frequently infested with *Ascaris equorum,* producing malnutrition and anaemia, but the large intestine is the great worm reservoir for the horse. Here the *strongyles* are found, of which both larvae and adults induce disease. The former taken in with the food, penetrate the mucous membrane, reach certain tissues and blood vessels and finally return to the bowel. *Sclerostoma tetracantha* has a similar cycle except that it does not enter the blood vessels or distant tissues. Its symptoms are emaciation, foetid diarrhoea and weakness. The egg-laying females of *Oxyuris curvula* pass from the bowel to the anal region and produce pruritus. The *botfly* passes its larval stage in the stomach and when the larvae are numerous may cause disease. In sheep and cattle the common fluke *Distoma hepaticum* infests the liver, causing the highly fatal "liver rot." Small *stomach strongyles* produce serious effects in young cattle and lambs, with inflammation and diarrhoea, followed by death from exhaustion. In cattle, sheep and pigs small *thread-worms* induce bronchitis, husk, and pneumonia. None of these parasites multiplies inside the host; eggs and larvae pass to the exterior in the droppings or sputum, undergo certain changes, and return with the food. *Tapeworms* infest the domestic animals, particularly dogs and lambs. The larval *Hydatids,* or bladder-worms, are found in various organs, brain, liver, muscles, etc., causing giddiness and paralysis. Pigs are frequently infested with *Ascaris lumbricoides,* which may cause obstruction when numerous, and may wander into the bile ducts and induce fatal jaundice. External parasites cause disease of the skin, *e.g.,* mange, scab and ring-worm in all domestic animals. Ticks and various flies are responsible for transmitting diseases due to blood parasites, *e.g.,* redwater in cattle (England), Texas fever, equine biliary fever, jaundice in dogs, surra in horses and camels, heartwater in ruminants (South Africa). Much advance has recently been made in the treatment of these diseases by organic compounds of arsenic, antimony, etc.

(F. BU.; F. T. H.)

VETO, generally the right of preventing any act, or its actual prohibition; in public law, the constitutional right of the competent authority, or in republics of the whole people in their primary assembly, to protest against a legislative or administrative act, and to prevent wholly or temporarily, its validation or execution. *See* CONSTITUTION AND CONSTITUTIONAL LAW.

VETTER, a lake of south Sweden, 80 m. long and 18 m. in extreme breadth, 733 sq.m. in area, 390 ft. maximum depth, and an elevation above sea-level of 289 ft. It drains by the Motala river to the Baltic. Its waters are remarkably transparent and blue, its shores picturesque and steep on the east side, where the Omberg (863 ft.) rises abruptly, with furrowed flanks pierced by caves. The lake is subject to sudden storms. Its northern part is crossed from Karlsborg to Motala by the Göta canal route. At the southern end is the important manufacturing town of Jönköping, and 15 m. N. of it the picturesque island of Vising. Vadstena, 8 m. S. of Motala, with a staple industry in lace, has a convent (now a hospital) of St. Bridget (1383), a beautiful monastic church (1395–1424) and a castle of King Gustavus Vasa. At Alvastra, 16 m. S., are ruins of a Cistercian monastery (11th century).

VETULONIA, an ancient town of Etruria, Italy. It lies 1,130 ft. above sea-level, about 10 m. directly N.W. of Grosseto, on the north-east side of the hills which project from the flat Maremma and form the promontory of Castiglione. In Etruscan times there was a bay here. Silius Italicus tells us that it was hence that the Romans took their magisterial insignia (fasces, curule chair, purple toga and brazen trumpets), and it was undoubtedly one of the twelve cities of Etruria. There are remains of the acropolis walls of massive limestone, in almost horizontal course, and also of houses and a street of the Roman period.

The earliest tombs found belong to the Villanovan period (First Benacci to late Second Benacci stage). Next come transitional tombs (in some of which hut-urns are found) surrounded by a ring of stones, and a few graves which are very early Etruscan: and then a group of important palaeo-Etruscan tombs (850–700 B.C.), most of them circle graves, in which objects of very great value and interest have been found. The objects found are in the museum at Florence.

See Randall MacIver, *Villanovans and Early Etruscans* (1924).

VEVEY, a small town in the Swiss canton of Vaud, near the eastern extremity of the Lake of Geneva. In 1920 it had a population of 12,768, of whom 9,634 were French-speaking, while there were 8,692 Protestants, 3,835 Roman Catholics and 74 Jews.

Vevey was a Roman settlement (*Viviscus*) and later formed part of the barony of Vaud, that was held by the counts and dukes of Savoy till 1536, when it was conquered by Bern. In 1798 it was freed from Bernese rule and became part of the canton du Léman (renamed canton de Vaud in 1803) of the Helvetic Republic. Vevey is by rail 12 m. S.E. of Lausanne, and is well served by steamers plying over the Lake of Geneva. It is the second town in point of population in the canton. It stands at the mouth of the Veveyse, and commands fine views of the mountains. The whole of the surrounding country is covered with vineyards. Every twenty years or so the *Fête des Vignerons* is held here by an ancient gild of vinedressers. It was last held in 1927.

VEXILLUM, the name for a small ensign consisting of a square cloth suspended from a cross-piece fixed to a spear [Lat. dim. of *velum,* piece of cloth, sail, awning, or from *vehere, vectum,* to carry]. The *vexillum* was strictly the ensign of the maniple, as *signum* was of the cohort, but the term came to be used for all standards or ensigns other than the eagle (*aquila*) of the legion (*see* FLAG). Caesar (*B.G.* ii. 20) uses the phrase *vexillum proponere* of the red flag hoisted over the general's tent as a signal for the march or battle. The standard-bearer of the maniple was styled *vexillarius,* but by the time of the Empire *vexillum* and *vexillarius* had gained a new significance. Tacitus uses these terms frequently both of a body of soldiers serving apart from the legion under a separate standard and also with the addition of some word implying connection with a legion of those soldiers who, after serving 16 years with the legion, continued their serv-

ice, under their own *vexillum*, with the legion (*see* also COLOURS, MILITARY). The term is also used for the scarf wrapped round a bishop's pastoral staff (*q.v.*). Modern science has adopted the word for the web or vein of a feather of a bird and of the large upper petal of flowers, such as the pea.

VÉZELAY, a village of France, in the department of Yonne, 10 m. W.S.W. of Avallon by road. Its population, which was over 10,000 in the middle ages, was 421 in 1926. The history of Vézelay is bound up with its Benedictine abbey, which was founded in the 9th century under the influence of the abbey of Cluny. The acquisition of the relics of St. Magdalen, soon after its foundation, began to attract crowds of pilgrims, whose presence enriched both the monks and the town which had grown up round the abbey and acknowledged its supremacy. In the 12th century the exactions of the abbot Artaud and the refusal of the monks to grant political independence to the citizens resulted in an insurrection in which the abbey was burnt and the abbot murdered. During the next fifty years three similar revolts occurred, fanned by the counts of Nevers. During the 12th century Vézelay was the scene of the preaching of the second crusade in 1146, and of the assumption of the cross in 1190 by Richard Coeur de Lion and Philip Augustus. The influence of the abbey began to diminish in 1280; its decline was hastened during the wars of religion of the 16th century.

Vézelay stands on a hill on the left bank of the Cure, and still preserves most of its ancient ramparts, notably the Porte Neuve, consisting of two massive towers flanking a gateway. The famous church of La Madeleine dates from the 12th century and was restored by Viollet-le-Duc. It consists of a narthex, with nave and aisles; a triple nave, without triforium, entered from the narthex by three doorways; transepts; and a choir with triforium. The oldest portion of the church is the nave, constructed about 1125. Its groined vaulting is supported on wide, low, semicircular arches, and on piers and columns, the capitals of which are finely carved. The narthex was probably built about 1140. The central entrance, leading from it to the nave, consists of two doorways, divided by a central pier supporting sculptured figures, and is surmounted by a carved tympanum. The choir and transepts are later in date than the rest of the church, which they surpass in height and grace of proportion. They were doubtless built in place of a Romanesque choir damaged in a fire in 1165. A crypt beneath the choir is perhaps the relic of a previous Romanesque church which was destroyed by fire in 1120. The west façade of the Madeleine has three portals; that in the centre is divided by a pier and surmounted by a sculptured tympanum. The upper portion of this front belongs to the 13th century.

VIANDEN, an ancient town in the grand duchy of Luxembourg, on the banks of the Our, close to the Prussian frontier. Pop. about 2,500. It possesses one of the oldest charters in Europe, granted early in the 14th century by Philip, count of Vianden, who was the ancestor of William of Orange. The original name of Vianden was Viennensis or Vienna. The ruins of the ancient castle stand on an eminence of the little town. Its size and importance in its prime may be gauged from the fact that the Knights' Hall could accommodate five hundred men-at-arms. A feature of the chapel is a hexagonal hole in the centre of the floor, opening upon a bare subterranean chamber, which seems to have been constructed by order of the crusader Count Frederick II. on the model of the Church of the Holy Sepulchre.

VIAREGGIO, a maritime town and sea-bathing resort of Tuscany, Italy, in the province of Lucca, on the Mediterranean, 13 m. N.W. of Pisa by rail, 7 ft. above sea-level. Pop. (1921) 25,224 (town), 27,618 (commune). Being sheltered by dense pine-woods on the north, it is frequented as a winter resort, and in summer by some thousands for its sea-bathing. In 1740 the population was only 300, and in 1841, 6,549. The body of Shelley was burned on the shore near Viareggio after his death by drowning in 1822. At Varignano near Viareggio is a large oil refinery.

VIATICUM, a Latin word meaning "provision for a journey" (Gr. τὰ ἐφόδια), is used by early Christian writers to denote anything that gave spiritual comfort to the dying. Ultimately it came to be restricted to the last communion given to the dying. In extreme cases the viaticum may be given to persons not fasting, and the same person may receive it frequently if his illness be prolonged. The ritual administration is that prescribed for the communion of the sick, except in the formula "Accipe, frater (soror), viaticum corporis Domini nostri Jesu Christi, qui te custodiat ab hoste maligno, et perducat in vitam aeternam. Amen." The viaticum is given before extreme unction, a reversal of the mediaeval practice due to the importance of receiving the Eucharist while the mind is still clear.

VIBORG, a town of Denmark, capital of the *amt* (county) of its name, lying in the district of Jutland, on Viborg lake. Pop. (1928), 15,357. The most notable building is the cathedral (1130–69, restored 1864–76). It contains some famous modern paintings by Joachim Skovgaard. The Black Friars' church is of the 13th century, and the museum possesses specimens of the Stone, Bronze and Iron Ages. The Borgevold Park borders the lake on the site of a former castle. The industries embrace distilleries, iron foundries and manufactures of cloth. There is beautiful scenery in the hilly country near Lake Hald, to the south.

VIBORG: *see* VIIPURI.

VIBURNUM, a genus of handsome shrubs (rarely small trees) of the honeysuckle family (Caprifoliaceae, *q.v.*), comprising about 110 species, found in temperate and subtropical regions, especially in eastern Asia and North America, many of which are planted for ornament. They are usually upright rather large shrubs with opposite, simple, medium-sized leaves, and numerous flowers, mostly in large umbel-like clusters, the marginal flowers sometimes enlarged and sterile. The fruit is a drupe, often highly coloured, with a single, usually flattened stone. Two species are native to Great Britain: *V. Lantana* (wayfaring-tree), found widely also in Europe and naturalized in the eastern United States; and *V. Opulus* (guelder-rose), indigenous to Europe and Asia. The common snowball of the gardens is a floral variant of the latter. In the United States and Canada some 15 species occur, several of which are widely distributed. Four species attain the size of trees: *V. Lentago* (nanny-berry), *V. prunifolium* (black haw), *V. rufidulum* (rusty black haw) and *V. obovatum* (small viburnum). Well-known shrubby species are *V. trilobum* (high-bush cranberry), *V. alnifolium* (hobble-bush), *V. dentatum* (arrow-wood), and *V. acerifolium* (dockmackie).

Besides the foregoing many other species are cultivated for their ornamental foliage, flowers and fruit.

VICAR, a title, more especially ecclesiastical, describing various officials acting in some special way for a superior. Cicero uses *vicarius* to describe an under-slave kept by another slave as part of his private property. The *vicarius* was an important official in the reorganized empire of Diocletian. It remained as a title of secular officials in the middle ages, being applied to persons appointed by the Roman emperor to judge cases in distant parts of the empire, or to wield power in certain districts, or, in the absence of the emperor, over all the empire. In the early middle ages the term was applied to representatives of a count administering justice for him in the country or small towns and dealing with unimportant cases, levying taxes, etc. Monasteries and religious houses often employed a vicar to answer to their feudal lords for those of their lands which did not pass into mortmain.

The title of "vicar of Jesus Christ," borne by the popes, was introduced as their special designation during the 8th century, in place of the older style of "vicar of St. Peter" (or *vicarius principis apostolorum*).

All bishops were looked upon as in some sort vicars of the pope, but the title *vicarius sedis apostolicae* came especially to be applied as an alternative to *legatus sedis apostolicae* to describe papal legates to whom in certain places the pope delegated a portion of his authority. Pope Benedict XIV. tells us in his treatise *De synodo dioecesana* that the pope often names vicars-apostolic for the government of a particular diocese because the episcopal see is vacant or, being filled, the titular bishop cannot fulfil his functions. The Roman Catholic Church in England was governed by vicars-apostolic from 1685 until 1850, when Pope Pius IX. re-established the hierarchy. Vicars-apostolic at the present day are nearly always titular bishops taking their titles from places not

acknowledging allegiance to the Roman Catholic Church.

Sometimes the pope appointed a neighbouring bishop as the vicar of a church which happened to be without a pastor. A special vicar was appointed by the pope to superintend the spiritual affairs of Rome and its suburbs, to visit its churches, monasteries, etc., and to correct abuses. It became early a custom for the prebendaries and canons of a cathedral to employ "priest-vicars" or "vicars-choral" as their substitutes when it was their turn as hebdomadary to sing High Mass and conduct divine office. In the English Church these priest-vicars remain in the cathedrals of the old foundations as beneficed clergy on the foundation; in the cathedrals of the new foundation they are paid by the chapters. "Lay vicars" also were and are employed to sing those parts of the office which can be sung by laymen. The incumbent of a parish where the titles are impropriate is entitled vicar.

In the Anglican Church a vicar-general is employed by the archbishop of Canterbury and some other bishops to assist in such matters as ecclesiastical visitations. In the Roman Catholic Church bishops sometimes appoint lesser vicars to exercise a more limited authority over a limited district. They are called "vicars-forane" or rural deans. They are entrusted especially with the surveillance of the parish priests and other priests of their districts, and with matters of ecclesiastical discipline. They are charged especially with the care of sick priests and in case of death with the celebration of their funerals and the charge of their vacant parishes. In canon law priests doing work in place of the parish priest are called vicars. Thus in France the *curé* or head priest in a parish church is assisted by several *vicaires*.

See Du Cange, *Glossarium mediae et infiniae Latinitatis*, ed. L. Favre (Niort, 1883, etc.); Migne, *Encyclopédie théologique*, series i. vol. 10 (Droit Canon); Comte de Mas Latrie, *Trésor de chronologie* (Paris, 1889); and Sir R. J. Phillimore, *Ecclesiastical Law of the Church of England* (2nd ed. 1895).

VICENTE, GIL (*c.* 1465–1536?), sometimes called the Portuguese Shakespeare, was born in the latter part of the reign of King Alphonso V. The first half of his life is vague. He was of humble birth and almost certainly spent his boyhood in some mountain village of the north of Portugal. He was perhaps apprenticed later to his father or uncle, Martim Vicente, goldsmith of Guimarães, and first came to the court at Evora, with many other provincials, on the occasion of the marriage of King João II.'s young son and heir to a daughter of the Catholic king in 1490. His work as goldsmith attracted the attention of Queen Lianor, and after the death of her son in 1491, and her husband four years later and the accession of her brother Manuel, Vicente retained her favour. It was at her request that he contributed (in 1509) a few verses to a poetical contest printed in the *Cancioneiro Geral* (1516). On the evening of June 7, 1502, the day after the birth of King Manuel's heir, the future João III., Vicente with a few others, dressed as herdsmen, entered the queen's chamber and recited a rustic monologue of 114 lines in Spanish. This primitive *Auto da Visitaçam* pleased Queen Lianor, and for the following Christmas Vicente had ready a longer but equally simple *Auto Pastoril Castelhano*.

For the next 34 years he was a kind of poet laureate, accompanying the court from Lisbon to Almeirim, Thomar, Coimbra or Evora and staging his plays to celebrate great events and the solemn occasions of Christmas, Easter and Maundy Thursday. The departure of a Portuguese fleet on the expedition against Azamor in 1513 turned his attention to more national themes, and in the *Exhortação da Guerra* (1513) and *Auto da Fama* (1515), inspired by the splendid victories of Albuquerque in the East, he wrote fervent patriotic verse which still stirs the hearts of his countrymen. Vicente's first wife, Branca Bezerra, may have died at about this time, and it seems that he was a widower when in 1514 he produced the charming *Comedia do Viuvo*.

His career as goldsmith kept pace with his growing success as dramatist. In 1509 he was appointed overseer of works in gold and silver at Thomar and elsewhere; in 1512 he was elected to the Lisbon Guild of Goldsmiths, and in Oct. 1513 he became one of their four representatives on the Lisbon town council. On Feb. 4 of this year he was appointed master of the Lisbon mint, a post which he resigned on Aug. 6, 1517, in favour of Diogo Rodriguez, whose sister Melicia he married, perhaps in the same year. After the death of King Manuel in 1521 and of Queen Lianor four years later, Vicente frequently complains of poverty, but he received various pensions in the new reign; his accomplished daughter Paula won the favour of Princess Maria (1521–77); and he enjoyed the personal friendship of King João III.

On the occasion of the departure by sea of King Manuel's daughter Beatriz to wed the duke of Savoy in Aug. 1521, Vicente's *Cortes de Jupiter* was acted in a large room "adorned with tapestry of gold," a fact chronicled by his friend, the poet Resende. The *Fragoa de Amor* (1524) was also written for a court occasion, the betrothal of King João III. to the sister of the Emperor Charles V. In the *Auto Pastoril Portugues* (1523), the farce *O Juiz da Beira* (1525), the *Tragi-comedia da Serra da Estrella* (1527) and the satirical *O Clerigo da Beira* (1529–30) he returned to the people, to the peasants and shepherds of the Beira mountain country which he knew so intimately.

He devoted himself more and more to the stage and multiplied himself in answer to the critics of Sá de Miranda's school. In 1526 came the *Templo de Apolo*, followed in rapid succession by the biblical play *Sumario da Historia de Deus*, the *Nao de Amores*, the *Divisa da Cidade de Coimbra*, and the *Farsa dos Almocreves*. These last three plays, with the *Serra da Estrella*, were all produced before the court in 1527 at Lisbon and Coimbra. On the other hand the *Auto da Festa* appears to have been acted in a private house at Evora. The elaborate *Auto da Feira* (1528) with its living popular types, contains some exceedingly caustic satire against Rome (personified on the stage): "You remit the sins of the whole world and forget to shrive yourself." It must be remembered that this was not a question of religion but of national politics: the relations of the devout João III. with the Vatican were often as troubled as those of his equally pious and even more regalist nephew Philip II. of Spain.

Vicente was now over 60, but he retained his vigour and versatility. The brilliant scenes of two of his last plays, the *Romagem de Agravados* (1533) and the *Floresta de Enganos* (1536), are loosely put together, and may well be earlier work; but the lyrical power of the *Triunfo do Inverno* (1529) and the long, compact *Amadis de Gaula* (1532) prove that his hand had lost none of its cunning and that his mind remained alert and young. The *Auto da Mofina Mendes* (1534), partly a religious allegory, partly a version of "Pierrette et son pot au lait," shows his old lightness of touch and penetrating charm. The *Auto da Lusitania*, which was acted in the presence of the court in 1532, may with some plausibility be identified with the *Caça de Segredos* at which Vicente tells us he was at work in 1525. It was the last of his plays to be staged at Lisbon in his lifetime; in Lent of 1534, by request of the abbess of the neighbouring convent of Odivelas, he produced there his religious *Auto da Cananea*, but the remainder of his plays were acted before the king and court at Evora; and it was probably at Evora that Vicente died in the year of his last play (1536).

Vicente's 44 plays admirably reflect the tragi-comedy of his age of change and upheaval in all its splendour and its squalor. Eleven are written exclusively in Spanish, 14 in Portuguese; the rest are bilingual; scraps of church or medical or law Latin, of French and Italian, of the dialect or slang of peasants, gipsies, sailors, fairies and devils frequently occur. His drama may be divided into religious plays, foreshadowing the Calderon *autos*, court plays, pastoral plays, popular farces and romantic comedy. They were often elaborately staged: a ship was rowed on the scene, or a tower opened to display some splendid allegory; here too he forestalled the later Spanish drama.

The various plays of the years 1513–19, composed when he was about 50, show Vicente at the height of his genius. He possessed a genuine comic vein, an incomparable lyric gift, and the power of seizing touches of life or literature and transforming them into something new by the magic of his phrase and his satiric force, under which lay a strong moral and patriotic purpose.

A far-sighted patriot and imperialist, and intensely national, he was also a devout son of the church; but he belonged to the more

outspoken days before the Reformation, and his satire of priests and of the abuses of Rome was frank and merciless; so that when in 1531 one of his plays, the *Jubileu de Amores* (which some critics would identify with the *Auto da Feira*) was acted at Brussels, the papal nuncio, Cardinal Aleandro, who was present, felt "as if I were in mid-Saxony listening to Luther or in the horrors of the sack of Rome." As a lyric poet Vicente is first seen at his best in the wonderful poems of the *Auto da Sibila Cassandra* (1513?) in Spanish. This poet, who goes to the very heart of the Portuguese people, can as a lyric poet occasionally rival and even excel Camões, who, as Prof. W. P. Ker remarked, is "less of a miracle than Vicente" and owed more to the Renaissance. Vicente was over 50 when Sá de Miranda brought the new forms and metres from Italy; in their rivalry Vicente remained faithful to the indigenous octosyllabic verse. He had to meet growing criticism, and, in answer to the taunts of pedants, borrowed from Gomez Manrique the proverb, "Better an ass that carries me than a horse that throws me," and, building on it the *Farsa de Ines Pereira,* turned the tables on the "men of good learning."

It is Vicente's originality that he is an artist of the Renaissance untainted by its pedantry. He is at once the most imitative and the most original of poets; we continually find him working up his borrowed material, like gold in the hands of an artist of genius, into concrete figures; and his rapidly sketched portraits of peasant, priest and courtier will last as long as literature. Even in his rudest plays, and when the execution is at its roughest, his bold plastic genius makes itself felt. His plays are rich in folklore, and in his love of all that was popular and indigenous he seized on the essential and eternal elements of art. His knowledge of the French language was small, the influence of France came to him through Spain, and his *Barcas* were inspired by the Spanish version of the Dance of Death. The Spanish influence is always strong in this most national poet; he even quotes from the Book of Job, not direct but through Garci Sanchez de Badajoz. He had studied very carefully the work of the early Spanish playwrights Gomez Manrique and Encina, although he soon surpassed them. No other country produced so inspired a dramatic poet before the second half of the 16th century. Actor, stage-manager and author, Vicente was also goldsmith and musician; he wrote the settings for some of his own lyrics, delightful popular *romances* and *cossantes* interspersed in his plays, which often end and open with a song, and are sometimes, as in the *Auto da Alma,* one long lyric.

Vicente is no exception to the general rule that Portuguese literature is mainly lyrical, in prose and verse; but in his many-sidedness he delineated life in its various aspects with the skill of a master, and he is the true forerunner of writers so different as Molière, Lope de Vega, Calderon and Shakespeare.

BIBLIOGRAPHY.—The only collected editions of Vicente's plays, a few of which were printed separately in his lifetime (seven of these were placed on the Portuguese Index of 1551), are the folios of Lisbon (1562 and 1586); the 3 vols. of Hamburg (1834) and Lisbon (1852); and the modern edition by Dr. Mendes dos Remedios (3 vols., Coimbra, 1907–14). The critical edition of the 1562 text prepared by Mme. Michaëlis de Vasconcellos immediately before her death has not yet seen the light. The only English translations are A. F. G. Bell, *Lyrics of Gil Vicente* (1914; 3rd ed. 1921) and *Four Plays of Gil Vicente* (1920). *See* E. Prestage, "The Portuguese Drama in the 16th Century; Gil Vicente," in the *Manchester Quarterly* (July and Oct. 1897); M. Menéndez y Pelayo, *Antología de Poetas Líricos,* vol. vii.; T. Braga, *Gil Vicente e as origens do theatro nacional* (Porto, 1898); J. I. de Brito Rebello, *Gil Vicente* (1902 and 1912); C. Michaëlis de Vasconcellos, *Notas Vicentinas,* 4 vols. (Coimbra, 1912–22); A. Braamcamp Freire, *Vida e Obras de Gil Vicente* (Porto, 1919); and A. F. G. Bell, *Gil Vicente* (1921). For a fuller bibliography see *Four Plays of Gil Vicente* (1920). A new Vicente play, the *Auto da Festa,* was published from his library in 1906 by the Conde de Sabugosa. (A. B.)

VICENZA (anc. *Vicetia*), a town and episcopal see of Venetia, Italy, capital of the province of Vicenza, 42 m. W. of Venice by rail, 131 ft. above sea-level. Pop. (1901) 32,200 (town); 47,558 (commune); (1921) 42,628 (town), 60,267 (commune). It lies at the northern base of the Monti Berici, on both sides of the Bacchiglione, at its confluence with the Retrone. It was surrounded by 13th century walls, now mostly demolished. The town has many fine buildings by Andrea Palladio (*q.v.*). The best is the basilica, one of the finest works of the Renaissance, of which Palladio himself said that it might stand comparison with any similar work of antiquity, replacing the exterior of the Palazzo della Ragione, a Gothic building (1444–1477), which the colonnades of the basilica entirely enclose. Begun in 1549, it was finished in 1614. Close by is the Torre di Piazza (12th–15th cent.) 270 ft. high, and here are also the Loggia del Capitanio, by Palladio (1571) and the long Lombardesque Monte di Pietà (16th cent.). He also designed many of the fine palaces which give Vicenza its individuality; only two, the Porto Barbaran and Chiericati palaces (the latter containing the picture gallery), have two orders of architecture, the rest having a heavy rustica basis with only one order above it. Many palaces attributed to him are really the work of Scamozzi (the architect of the fine Palazzo del Municipio, 1588) and others of his successors. The famous Teatro Olimpico begun by him, but finished in 1583, is a remarkable attempt to construct a theatre in the ancient style, and the stage, with the representation of streets ascending at the back, is curious. The Italian Gothic cathedral (mainly 13th cent.), consists of a nave with eight chapels on each side, and a very high Renaissance domed choir. The churches of S. Lorenzo (1280–1344) and S. Corona (1260–1300), both of brick, are better examples of Gothic; both contain interesting works of art—the latter a very fine "Baptism of Christ," by Giovanni Bellini. The church of SS. Felice e Fortunato was restored in 975, but has been much altered, and was transformed in 1613. The portal is of 1154, and the Lombardesque square brick tower of 1166. Under it lies a mosaic pavement with the names of the donors, belonging to the original church of the Lombard period (?). Of the Palladian villas in the neighbourhood, La Rotonda, 1½ m. S.E., is a square building with Ionic colonnades and a central dome which has been more than once copied in England and France. Near by is the Villa Valmarana, with fine frescoes by G. B. Tiepolo (1737), and the new Piazzale della Vittoria, behind which is the baroque church of Monte Berico, with good works of art, from which porticoes lead down to the tower. Vicenza also has palaces in the Venetian Gothic style.

The ancient *Vicetia* was of less importance than Verona and Patavium. It was for some time during the middle ages an independent republic, but was subdued by the Venetians in 1405. Towards the end of the 15th century it became the seat of a school of painting strongly influenced by Mantegna, of which the principal representatives were Bartolomeo Montagna, its founder, his son Benedetto Montagna, more important as an engraver, Giovanni Speranza and Giovanni Buonconsiglio. Andrea Palladio (1518–1580) was a native of Vicenza, as was also a contemporary, Vincenzo Scamozzi (1552–1616), who was largely dependent on him, but is better known for his work on architecture (*Architettura universale,* 1615). Palladio inaugurated a school of followers who continued to erect similar buildings in Vicenza even down to the French Revolution. Other natives of Vicenza were Giangiorgio Trissino (1478–1553) (*see* ITALIAN LITERATURE, PALLADIO), Antonio Pigafetta (1491–1534) and Antonio Fogazzaro (1842–1911) *q.v.* (T. A.)

See G. Pettinà, *Vicenza* (Bergamo, 1905).

VICKERS LIMITED, one of the greatest British iron and steel manufacturers, shipbuilders, engineers and armament manufacturers. This joint-stock company, which in 1928 had a share capital of roundly £12,500,000, was founded a century ago. In 1828 George Naylor and his son-in-law, Edward Vickers, began business in a small way in the production of steel for cutting tools, files, and so forth, and until 1865 their works were at Wadsley and Sheffield. The firm was transformed in 1867 into a limited company as Vickers Sons and Company.

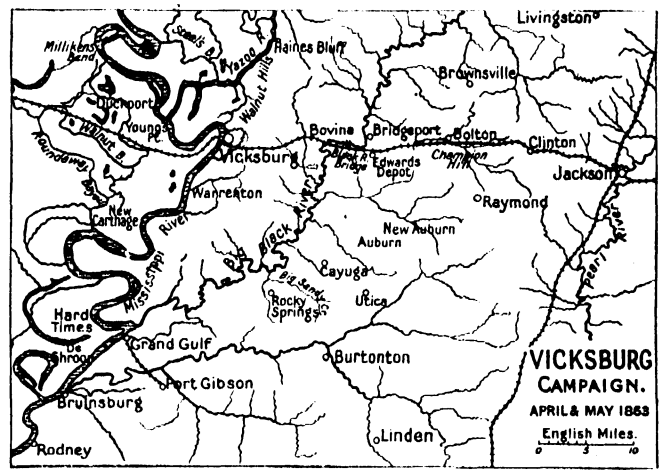
As early as 1869 the company made steel forgings for guns, and this business developed strongly after 1880. In 1888 the firm decided to build complete guns, put down the necessary machinery and obtained some orders from the British Government. Not long after they set up their own designing staff, without which trade with foreign governments was impossible. The Maxim Nordenfelt Guns and Ammunition Company and the Naval Armaments Company with a shipyard at Barrow-in-Furness were bought up in

1897, and from that time the company made artillery ranging from the rifle calibre machine gun to the heaviest naval ordnance. The company were now in a position to build warships at Barrow completely equipped with armour and guns made at the Sheffield works, for armour plate manufacture had also been taken up.

After the World War the capital of the company amounted to £13,500,000, to which it had risen by successive issues from £155,000, the original figure at the formation of the limited company in 1867. By the acquisition of control of the British Westinghouse Company and the Metropolitan Carriage Company this was raised to £20,663,188.

Several ventures into heavy engineering were tried, but the boom in trade after the war due to replacements of losses and deferred repairs soon came to an end, and it became evident that the earning power of the company's works was not commensurate with the capital invested in them. The capital was drastically written down in 1926, unremunerative businesses were closed, and the system of management changed and decentralized. The reduced earning power of the works had not brought financial stress; the firm had always large cash resources. By 1928 it was shown that the reforms had been very successful.

During 1927 negotiations with Sir W. G. Armstrong Whitworth and Company Ltd. led to an agreement under which the armament and naval shipbuilding sides of both firms were merged in a joint company under the style of Vickers Armstrongs Limited.



(L. C. M.)

VICKSBURG, a city of western Mississippi, U.S.A., on the Mississippi river, at the mouth of the Yazoo, about midway between Memphis and New Orleans; the county seat of Warren county. It is on Federal highways 61 and 80 and is served by the Illinois Central system and river steamers and barges. Construction of a bridge across the Mississippi (for vehicular, railway and pedestrian traffic) was begun in 1928. Pop. 18,072 in 1920, 51% negroes, and was estimated locally at 25,000 in 1928. The city is built on a high bluff, rising to 350 ft. above sea-level.

On the landward side the city is completely surrounded by the Vicksburg National Military park (1,323 ac.), and beyond the northern end of the park, fronting on the river, is one of the largest and most beautiful of the national cemeteries, containing 16,727 graves of Union soldiers, of which 12,723 are marked "unknown." The park includes the battle lines of the opposed armies during the investment of Vicksburg, May 18 to July 4, 1863 (*see* below), and all the fighting ground between them. About 900 bronze markers tell the story, and three observation towers afford comprehensive panoramas of the field. There are 15 State memorials, scores of statues and busts of Union and Confederate commanders, and on Oct. 13, 1927, a bronze statue of Jefferson Davis (by Henry H. Kitson) was unveiled, and presented by the State of Mississippi to the United States. There are many beautiful ante-bellum residences in the city and its environs. Vicksburg is an important cotton and hardwood lumber market. It has railroad and machine shops, lumber mills, cotton-seed-oil mills, and factories making furniture, boxes, baskets, veneer, hoops, staves and oars. The factory output in 1925 was valued at $4,489,664. The city has a commission form of government.

Early in the 18th century the French built Ft. St. Peter near the site of Vicksburg, and on Jan. 2, 1730, its garrison was massacred by the Yazoo Indians. In 1783 the Spaniards erected Ft. Nogales, which was taken by U.S. troops in 1798 and renamed McHenry. The first permanent settlement was made about 1811 by the Rev. Newitt Vick (d. 1819), a Methodist preacher, and in accordance with his will a town was laid out in 1824. It was incorporated in 1825 and chartered as a city in 1836.

The Campaign of 1862 to 1863.—Vicksburg is historically famous as being the centre of interest of one of the most important campaigns of the American Civil War. The command of the Mississippi, which would imply the severance of the Confederacy into two halves, and also the reopening of free commercial navigation from St. Louis to the sea, was one of the principal objects of the Western armies of the Union from the time that they began their southward advance from Illinois, Missouri and Kentucky in Feb. 1862. A series of victories in the spring and summer carried them as far as the line Memphis–Corinth, but in the autumn they came to a standstill and were called upon to repulse the counter-advance of the Southern armies. The Federals were accompanied by a flotilla of thinly armoured but powerful gunboats which had been built on the upper Mississippi in the autumn of 1861, and had co-operated with the army at Fort

Donelson, Shiloh and Island No. 10, besides winning a victory on the water at Memphis.

At the same time a squadron of sea-going vessels under Flag-officer Farragut had forced the defences of New Orleans (*q.v.*) and, accompanied by a very small military force, had steamed up the great river. On reaching Vicksburg the heavy vessels again forced their way past the batteries, but they had to deal, no longer with low-sited fortifications, but with inconspicuous earthworks on bluffs far above the river-level, and they failed to make any impression. Farragut then returned to New Orleans. From Helena to Port Hudson the Confederates maintained complete control of the Mississippi, the improvised fortresses of Vicksburg, Port Hudson and Arkansas Post (near the mouth of Arkansas river) being the framework of the defence. It was to be the task of Grant's army around Corinth and the flotilla at Memphis to break up this system of defences, and, by joining hands with Farragut and clearing the whole course of the Mississippi, to cut the Confederacy in half.

The long and painful operations by which this was achieved group themselves into four episodes: (*a*) the Grenada expedition of Grant's force, (*b*) the river column under McClernand and Sherman, (*c*) the operations in the bayoux, and (*d*) the final "overland" campaign from Grand Gulf. The country in which these operations took place divides itself sharply into two zones; the upland east of the Mississippi below Vicksburg and east of the Yazoo above, and the levels west of this line, which are a maze of bayoux, backwaters and side channels, the intervening land being kept dry near the river itself by artificial banks (levees) but elsewhere swampy. At Vicksburg, it is important to observe, the bluffs trend away from the Mississippi to follow the course of the Yazoo, rejoining the great river at Memphis. Thus there are two obvious lines of advance for the Northern army, on the upland (Memphis and Grand Junction on Grenada–Jackson), and downstream through the bayou country (Memphis–Helena–Vicksburg). The main army of the defenders, who were commanded by General Pemberton, between Vicksburg and Jackson and Grenada, could front either north against an advance by Grenada or west along the bluffs above and below Vicksburg.

The first advance was made at the end of Nov. 1862 by two columns from Grand Junction and Memphis on Grenada. The Confederates in the field, greatly outnumbered, fell back without fighting. But Grant's line of supply was one long single-line, ill-equipped railway through Grand Junction to Columbus, and the opposing cavalry under Van Dorn swept round his flank and, by destroying one of his principal magazines (at Holly Springs), without further effort compelled the abandonment of the advance.

Grant then sent Sherman with the flotilla and some 30,000 men to attack Vicksburg from the water-side, while he himself should deal with the Confederate field army on the high ground. But the scheme broke down completely when Van Dorn cut Grant's line of supply, and the Confederate army was free to turn on Sherman. The latter, ignorant of Grant's retreat, attacked the Yazoo bluffs above Vicksburg (battle of Chickasaw Bayou) on Dec. 29; but a large portion of Pemberton's field army had arrived to help the Vicksburg garrison, and the Federals were easily repulsed with a loss of 2,000 men. General McClernand now appeared and took the command out of Sherman's hands, informing him at the same time of Grant's retreat. Sherman thereupon proposed, before attempting fresh operations against Vicksburg, to clear the country behind them by destroying the Confederate garrison at Arkansas Post. This expedition was completely successful: at a cost of about 1,000 men the fort and its 5,000 defenders were captured on Jan. 11, 1863.

Retreating from the upland, Grant sailed down the river and joined McClernand and Sherman at Milliken's Bend at the beginning of February, and assumed command of the three corps (XIII., McClernand; XV., Sherman; XVII., McPherson) available. He had already imagined the daring solution of his most difficult problem which he afterwards put into execution, but for the present he tried a series of less risky expedients to reach the high ground beyond Pemberton's flanks, without, indeed, much confidence in their success, yet desirous in these unhealthy flats of keeping up the spirits of his army by active work, and of avoiding, at a crisis in the fortunes of the war, any appearance of discouragement. Three such attempts were made in all, with the co-operation of the flotilla under Rear Admiral David D. Porter. First, Grant endeavoured to cut a canal across the bend of the Mississippi opposite Vicksburg, hoping thus to isolate the fortress, to gain a water connection with the lower river, and to land an army on the bluffs beyond Pemberton's left flank. This was unsuccessful. Next he tried to make a practicable channel from the Mississippi to the upper Yazoo, and so to turn Pemberton's right, but the Confederates, warned in time, constructed a fort at the point where Grant's advance emerged from the bayoux. Lastly, an advance through a maze of creeks (Steele's Bayou expedition), towards the middle Yazoo and Haines's Bluff, encountered the enemy, not on the bluffs, but in the low-lying woods and islands, and these so harassed and delayed the progress of the expedition that Grant recalled it. Shortly afterwards Grant determined on the manoeuvre in rear of Vicksburg which established his reputation. The troops marched overland from Milliken's Bend to New Carthage, and on April 16 Porter's gunboat flotilla and the transports ran past the Vicksburg batteries. All this, which involved careful arrangement and hard work, was done by April 24. General Banks, with a Union army from New Orleans, was now advancing up the river to invest Port Hudson, and by way of diverting attention from the Mississippi, a cavalry brigade under Benjamin Grierson rode from La Grange to Baton Rouge (600m. in 16 days), destroying railways and magazines and cutting the telegraph wires *en route*. Sherman's XV. Corps, too, made vigorous demonstrations at Haines's Bluff, and in the confusion and uncertainty Pemberton was at a loss.

Foiled at Grand Gulf on April 29, on the 30th McClernand and the XIII. Corps crossed the Mississippi 6m. below Grand Gulf, followed by McPherson. The nearest Confederate brigades, attempting to oppose the advance at Port Gibson, were driven back. Grant had now deliberately placed himself in the middle of the enemy, and although his engineers had opened up a waterline for the barges carrying his supplies from Milliken's Bend to New Carthage, his long line of supply curving round the enemy's flank was very exposed. But his resolute purpose outweighed all textbook strategy. Having crossed the Mississippi, he collected wheeled transport for five days' rations, and on Sherman's arrival cut loose from his base altogether (May 7). Free to move, he aimed north from the Big Black river, so as to interpose between the Confederate forces at Vicksburg and those at Jackson. A fight took place at Raymond on May 12, and Jackson was captured just in time to forestall the arrival of reinforcements for Pemberton under General Joseph E. Johnston. The latter, being in supreme command of the Confederates, ordered Pemberton to come out of Vicksburg and attack Grant. But Pemberton did not do so until it was too late. On May 16 Grant, with all his forces well in hand, defeated him in the battle of Champion Hill with a loss of nearly 4,000 men, and sharply pursuing him drove him into Vicksburg. By May 19 Vicksburg and Pemberton's army in it was invested by land and water. Grant promptly assaulted his works, but was repulsed with loss (May 19); the assault was repeated on May 22 with the same result, and Grant found himself compelled to resort to a blockade. Reinforcements were hurried up from all quarters. Johnston's force (east of Jackson), was held off by a covering corps under Blair (afterwards under Sherman), and though another unsuccessful assault was made on June 25, resistance was almost at an end. On July 4, the day after, far away in Pennsylvania, the great battle of Gettysburg had closed with Lee's defeat, the garrison of Vicksburg, 37,000 strong, surrendered.

See J. H. Wilson, "A Staff Officer's Journal of the Vicksburg Campaign," *Mil. Serv. Inst. Journ.*, vol. xliii., p. 93–109, 261–275 (1908); and W. L. Livermore, "The Vicksburg Campaign," *Mil. Hist. Soc. of Mass.*, vol. ix., p. 538–571 (Boston, 1912). For a personal side light, *see* U. S. Grant, "Letter to his Father on the Capture of Vicksburg, 1863," *Amer. Hist. Rev.*, vol. xii., p. 109 (Lancaster, Pa. 1906).

VICO, GIOVANNI BATTISTA (1668–1744), Italian jurist and philosopher, was born at Naples on June 23, 1668, and in 1697 became professor of rhetoric at the university there. Meanwhile he had acted as tutor to the nephews of the bishop of Ischia, G. B. Rocca, at the castle of Vatolla, near Cilento, in the province of Salerno. There he passed nine studious years, chiefly devoted to classical reading, Plato and Tacitus being his favourite authors, because "the former described the ideal man, and the latter man as he really is." Two authors exercised a weighty influence on his mind—Francis Bacon and Grotius. He was no follower of their ideas, indeed often opposed to them; but he was stimulated by Bacon to investigate certain great problems of history and philosophy, while Grotius led him to philosophic jurisprudence. In 1708 he published his *De ratione studiorum*, in 1710 *De antiquissima Italorum sapientia*, in 1720 *De universi iuris uno principio et fine uno*, and in 1721 *De constantia iurisprudentis*. He failed to secure the university chair of jurisprudence which he had hoped these works would secure for him. His great work, *Principii d'una scienza nuova* appeared in 1725 (2nd ed. 1730, which is practically a new work). In 1735 Charles III. of Naples made Vico historiographer-royal, with a yearly stipend of 100 ducats. Soon after his mind began to give way, but during frequent intervals of lucidity he made new corrections in his great work, of which a third edition appeared in 1744, prefaced by a letter of dedication to Cardinal Trojano Acquaviva. He died on Jan. 20, 1744, and was buried in the church of the Gerolimini.

Vico is perhaps the greatest name in the Neapolitan tradition of jurisprudence. His aim was the relation of the history of law to that of the human mind, and the problem with which he was faced is stated in its final form in the *Scienza Nuova*. The question is—if the principle of justice be one and immutable, how are the varying codes to be accounted for? His solution is offered in his *Universal Law* (*Diritto universale*).

Law, he held, emanates from the conscience of mankind, and participates in the changes of the human mind. The reasons for its changes, therefore, must be sought in the general history of human development. The primitive sentiment of justice is unconscious and instinctive, and expresses itself in religious forms of a concrete nature, mankind being at this stage incapable of abstract ideas (*cf.* Vinopadoff, *History of Jurisprudence*). These give place to abstract formula, and these in turn to the direct manifestation of the philosophic principles of law. Thus the history of Roman Law, for instance, can be divided into three parts, the divine, the heroic and the human, corresponding to the three main phases of general Roman history. Thus in the varying aspects of law Vico found the expression of a single fundamental principle.

This theory seems to have originated in his study of Roman law, which Vico saw as a continuous progress from the primitive

law of the XII. Tables to the universal and flexible *jus gentium*. This conception he generalized into a complete philosophy of history. The history of humanity he sees as a process of development from "poetic wisdom," the impersonal, religious, instinctive ideas of primitive society to "occult wisdom," which turns divinely implanted ideas into conscious philosophical wisdom. Like most discoverers of a system, however, Vico carried it further than it would go. His *law of cycles*, the "eternal ideal history, invariably followed by all nations," which is the expression of this theory, seeks to reduce the whole course of history to conformity with this threefold succession of phases, divine, heroic and human, which he sees exemplified in government, language, literature, jurisprudence and civilization.

See Vico's autobiography in the *Scienza Nuova*, and Sir J. Ferrari's introduction to his edition of the works of Vico (6 vols., Milan, 1835–37) and the more complete edition, including translation by Pomodoro of the Latin works (Naples, 8 vols., 1858–69). A complete bibliography was prepared by B. Croce, *Bibliographia Vichiana* (Naples, 1904). *See* also Cantoni, *Vico* (Turin, 1867); R. Flint, *Vico* ("Philosophical Classics," 1885); B. Croce, many articles in various Italian reviews and *La filosofia di Giambattista Vico* (Bari, 1911).

VICTOR, the name taken by three popes and two antipopes.

VICTOR I. was bishop of Rome from about 190 to 198. He submitted to the opinion of the episcopate in the various parts of Christendom the divergence between the Easter usage of Rome and that of the bishops of Asia. The bishops, particularly St. Irenaeus of Lyons, declared themselves in favour of the usage of Rome, but refused to associate themselves with the excommunication pronounced by Victor against their Asiatic colleagues.

VICTOR II., the successor of Leo IX., was consecrated in St. Peter's, Rome, on April 13, 1055. His father was a Swabian baron, Count Hartwig von Calw, and his own baptismal name was Gebhard. At the instance of Gebhard, bishop of Regensburg, uncle of the emperor Henry III., he had been appointed while still a young man to the see of Eichstädt; in this position his great talents soon enabled him to render important services to Henry, whose chief adviser he ultimately became. His nomination to the papacy by Henry, at Mainz, in September 1054, was made at the instance of a Roman deputation headed by Hildebrand, whose policy doubtless was to detach from the imperial interest one of its ablest supporters. In June 1055 Victor met the emperor at Florence, and held a council, which anew condemned clerical marriages, simony and the alienation of the estates of the church. In the following year he was summoned to Germany to the side of the emperor, and was with him when he died at Botfeld in the Harz on Oct. 5, 1056. As guardian of Henry's infant son, and adviser of the empress Agnes, Victor now wielded enormous power, which he began to use with much tact for the maintenance of peace throughout the empire and for strengthening the papacy against the aggressions of the barons. He died shortly after his return to Italy, at Arezzo, on July 28, 1057. His successor was Stephen IX. (X.)

VICTOR III. (Dauferius Epifani), pope from May 24, 1086 to Sept. 16, 1087, was the successor of Gregory VII. He was a son of Landolfo V., prince of Benevento, and was born in 1027. After studying in various monasteries he became provost of St. Benedict at Capua, and in 1055 obtained permission from Victor II. to enter the cloister at Monte Cassino, changing his name to Desiderius. He succeeded Stephen IX. as abbot in 1057, and his rule marks the golden age of that celebrated monastery; he promoted literary activity, and established an important school of mosaic. Desiderius was created cardinal priest of Sta. Cecilia by Nicholas II. in 1059, and as papal vicar in south Italy conducted frequent negotiations between the Normans and the pope. Among the four men suggested by Gregory VII. on his deathbed as most worthy to succeed him was Desiderius, who was favoured by the cardinals because of his great learning, his connection with the Normans and his diplomatic ability. The abbot, however, declined the papal crown, and the year 1085 passed without an election. The cardinals at length proclaimed him pope against his will on May 24, 1086, but he was driven from Rome by imperialists before his consecration was complete, and, laying aside the papal insignia at Terracina, he retired to his beloved monastery. As vicar of the Holy See he convened a synod at Capua on March 7, 1087, resumed the papal insignia on the 21st of March, and received tardy consecration at Rome on the 9th of May. Owing to the presence of the antipope, Clement III. (Guibert of Ravenna), who had powerful partisans, his stay at Rome was brief. He sent an army to Tunis, which defeated the Saracens and compelled the sultan to pay tribute to the papal see. In August 1087 he held a synod at Benevento, which renewed the excommunication of Guibert; banned Archbishop Hugo of Lyons and Abbot Richard of Marseilles as schismatics; and confirmed the prohibition of lay investiture. Falling ill at the synod, Vicar returned to Monte Cassino, where he died on Sept. 16, 1087. His successor was Urban II.

Victor III., while abbot of Monte Cassino contributed personally to the literary activity of the monastery. He wrote *Dialogi de miraculis S. Benedicti*, which, along with his *Epistolae*, are in J. P. Migne, *Patrol. Lat.* vol. 149, and an account of the miracles of Leo IX. (in *Acta Sanctorum*, 19th of April). The chief sources for his life are the "Chronica monasterii Casinensis," in the *Mon. Germ. hist. Script.* vii., and the Vitae in J. P. Migne, *Patrol. Lat.* vol. 149, and in J. M. Watterich, *Pontif. Roman. Vitae* (1862).

See J. Langen, *Geschichte der römischen Kirche von Gregor VII. bis Innocenz III.* (Bonn, 1893); F. Gregorovius, *Rome in the Middle Ages*, vol. 4, trans. by Mrs. G. W. Hamilton (London, 1900–02); K. J. von Hefele, *Conciliengeschichte* (2nd ed., 1873–90), vol. 5; Hirsch, "Desiderius von Monte Cassino als Papst Victor III.," in *Forschungen zur deutschen Geschichte*, vol. 7 (Göttingen, 1867); H. H. Milman, *History of Latin Christianity*, vol. 3 (repub., 1899).

VICTOR IV. was a title taken by two antipopes. (1) Gregorio Conti, cardinal priest of Santi Dodici Apostoli, was chosen by a party opposed to Innocent II. in succession to the antipope Anacletus II., on March 15, 1138, but through the influence of Bernard of Clairvaux he was induced to make his submission on the 29th of May. (2) Octavian, count of Tusculum and cardinal deacon of St. Nicola in carcere Tulliano, the Ghibelline antipope, was elected at Rome on Sept. 7, 1159, in opposition to Alexander III., and supported by the emperor Frederick Barbarossa. Consecrated at Farfa on the 4th of October, Victor was the first of the series of antipopes supported by Frederick against Alexander III. Though the excommunication of Frederick by Alexander in March 1160 made only a slight impression in Germany, this pope was nevertheless able to gain the support of the rest of western Europe, because since the days of Hildebrand the power of the pope over the church in the various countries had increased so greatly that the kings of France and of England could not view with indifference a revival of such imperial control of the papacy as had been exercised by the emperor Henry III. He died at Lucca on April 20, 1164 and was succeeded by the antipope Paschal III. (1164–1168).

See M. Meyer, *Die Wahl Alexanders III. und Victors IV. 1159* (Göttingen, 1871); and A. Hauck, *Kirchengeschichte Deutschlands* Band iv. (1922). (C. H. H.)

VICTOR, SEXTUS AURELIUS, prefect of Pannonia about 360 (Amm. Marc. xxi. 10), possibly the same as the consul (jointly with Valentinian) in 373 and as the prefect of the city who is mentioned in an inscription of the time of Theodosius. Four small historical works have been ascribed to him on more or less doubtful grounds—(1) *Origo Gentis Romanae*, (2) *De Viribus Illustribus Romae*, (3) *De Caesaribus*, (4) *De Vita et Moribus Imperatorum Romanorum excerpta ex Libris Sex. Aur. Victoris*. The four have generally been published together under the name *Historia Romana*, but the fourth is a *réchauffé* of the third.

The first edition of all four was that of A. Schottus (8vo, Antwerp, 1579). A good modern edition of the *De Caesaribus* is by F. Pichlmayr (Munich, 1892).

VICTOR AMEDEUS II. (1666–1732), duke of Savoy and first king of Sardinia, was the son of Duke Charles Emmanuel II. and Jeanne de Savoie-Nemours. Born at Turin, he lost his father in 1675, and spent his youth under the regency of his mother, known as "Madama Reale" (madame royale), an able but ambitious and overbearing woman. He assumed the reigns of government at the age of sixteen, and married Princess Anne, daughter of Philip of Orleans and Henrietta of England, and niece of Louis XIV., king of France. His first sign of independence was his visit to Venice in 1687, where he met Prince Eugène of Savoy

and other personages, without consulting Louis. Louis now tried to precipitate hostilities by demanding his participation in a second expedition against the Waldensians. The duke unwillingly complied, but when the French entered Piedmont and demanded the cession of the fortresses of Turin and Verrua, he refused, and while still professing to negotiate with Louis, joined the league of Austria, Spain and Venice. War was declared in 1690, but at the battle of Staffarda (Aug. 18, 1691), Victor was defeated by the French. A treaty with France was signed in 1696, and Victor appointed generalissimo of the Franco-Piedmontese forces in Italy operating against the imperialists. By the treaty of Ryswick (1697) a general peace was concluded.

On the outbreak of the war of the Spanish Succession in 1700 the duke was again on the French side, but the insolence of Louis and of Philip V. of Spain towards him induced him, at the end of the two years for which he had bound himself to them, to go over to the imperialists (1704). After some successes the French were completely defeated by Victor and Prince Eugène (1706). By the peace of Utrecht (1713) the Powers conferred the kingdom of Sicily on Victor Amedeus, whose government proved efficient and at first popular. But after a brief stay in the island he returned to Piedmont and left his new possessions to a viceroy; when the Quadruple Alliance decreed in 1718 that Sicily should be restored to Spain, Victor was unable to offer any opposition, and had to content himself with receiving Sardinia in exchange.

The last years of Victor Amedeus's life were saddened by domestic troubles. After his wife's death, he married the Contessa di San Sebastiano, abdicated the crown and retired to Chambéry to end his days (1730). But his second wife, an ambitious *intrigante*, induced him to return to Turin and attempt to revoke his abdication. This led to a quarrel with his son, Charles Emmanuel III., who arrested his father and confined him at Rivoli and later at Moncalieri; there Victor died on Oct. 31, 1732.

Victor Amedeus, not only won for his country a high place in the council of nations, but he doubled its revenues and increased its prosperity and industries.

See D. Carutti, *Storia del Regno di Vittorio Amedeo II.* (Turin, 1856); and E. Parri, *Vittorio Amedio II. ed Eugenio di Savoia* (Milan, 1888); C. A. Garuſi, *Rapporte diplomatici tra Filippo V. e Vittorio Amedeo di Savoia . . . 1712–1720* (Palermo, 1914). The Marchesa Vitelleschi's work, *The Romance of Savoy* (2 vols., London, 1905), is based on original authorities, and is the most complete monograph on the subject.

VICTOR EMMANUEL II. (1820–1878), king of Sardinia and first king of Italy, was born at Turin on March 14, 1820, and was the son of Charles Albert, prince of Savoy-Carignano. Brought up in the bigoted and chilling atmosphere of the Piedmontese court, he received a rigid military and religious training, but little intellectual education. In 1842 he married Adelaide, daughter of the Austrian Archduke Rainer. Victor Emmanuel played no part in politics during his father's lifetime, but took an active interest in military matters. When the war with Austria broke out in 1848, he was delighted at the prospect of distinguishing himself, and was given the command of a division. At Goito he was slightly wounded and displayed great bravery, and after Custozza defended the rearguard to the last (July 25, 1848). After the defeat at Novara on March 23, Charles Albert, having rejected the peace terms offered by the Austrian field-marshal Radetzky, abdicated in favour of his son. Victor Emmanuel was received by Radetzky with every sign of respect and the field-marshal offered not only to waive the claim that Austria should face of the overwhelming tide of reaction that established his position as the champion of Italian freedom and earned him the sobriquet of *Rè Galantuomo* (the honest king). But the task entrusted to him was a most difficult one. Parliament having rejected the peace treaty, the king dissolved the assembly; in the famous proclamation from Moncalieri he appealed to the people's loyalty, and the new Chamber ratified the treaty (Jan. 9, 1850). This same year, Cavour (*q.v.*) was appointed minister of agriculture in D'Azeglio's cabinet, and in 1852 became prime minister.

In having Cavour as his chief adviser Victor Emmanuel was most fortunate, and but for that statesman's astounding diplomatic genius the liberation of Italy would have been impossible. The years from 1850 to 1859 were devoted to restoring the shattered finances of Sardinia, reorganizing the army and modernizing the antiquated institutions of the kingdom. Among other reforms the abolition of the *foro ecclesiastico* (privileged ecclesiastical courts) brought down a storm of hostility from the Church both on the king and on Cavour, but both remained firm in sustaining the prerogatives of the civil power. When the Crimean War broke out, the king strongly supported Cavour in the proposal that Sardinia should join France and England against Russia so as to secure a place in the councils of the great powers and establish a claim on them for eventual assistance in Italian affairs (1854). In 1855, while the allied troops were still in the East, Victor Emmanuel visited Paris and London, where he was warmly welcomed by the Emperor Napoleon III. and by Queen Victoria, as well as by the peoples of the two countries.

Victor Emmanuel's object now was the expulsion of the Austrians from Italy and the expansion of Sardinia into a North Italian kingdom, but he did not regard the idea of Italian unity as coming within the sphere of practical politics for the time being, although a movement to that end was already beginning to gain ground. With this end in view he entered into communication with some of the conspirators, especially with La Farina, the leader of the *Società Nazionale*, and even communicated with Mazzini and the republicans. In 1859 Cavour's diplomacy succeeded in drawing Napoleon III. into an alliance against Austria, although the king had to agree to the cession of Savoy and possibly of Nice and to the marriage of his daughter Clothilde to the emperor's cousin Prince Napoleon. These conditions were very painful to him, but he was always ready to sacrifice his own personal feelings for the good of his country. He had an interview with Garibaldi and appointed him commander of the newly raised volunteer corps, the *Cacciatori delle Alpi*. Even then Napoleon would not decide on immediate hostilities, and it required all Cavour's genius to bring him to the point and lead Austria into a declaration of war (April 1859). Although the Franco-Sardinian forces were successful in the field, Napoleon, fearing an attack by Prussia and disliking the idea of a too powerful Italian kingdom on the frontiers of France, insisted on making peace with Austria, while Venetia still remained to be freed. Victor Emmanuel, realizing that he could not continue the campaign alone, agreed to the armistice of Villafranca. When Cavour heard the news he hurried to the king's headquarters at Monzambano, and in violent, almost disrespectful language implored him to continue the campaign at all hazards. But the king on this occasion showed great political insight and saw that by adopting the heroic course proposed by the latter he ran the risk of finding Napoleon on the side of the enemy, whereas by waiting all might be gained. Cavour resigned office, and by the peace

theory a republican, was greatly attached to the bluff soldier-king. When Garibaldi having conquered Sicily was determined to invade the mainland possessions of Francis II. of Naples, Victor Emmanuel, foreseeing international difficulties, wrote to the chief of the red shirts asking him not to cross the straits; but Garibaldi, although acting throughout in the name of his majesty, refused to obey and continued his victorious march, for he knew that the king's letter was dictated by diplomatic considerations rather than by his own personal desire. Then, on Cavour's advice, King Victor decided to participate himself in the occupation of Neapolitan territory, lest Garibaldi's doubtful entourage should proclaim the republic or create anarchy. When he accepted the annexation of Romagna offered by the inhabitants themselves the pope excommunicated him, but, although a devout Catholic, he continued in his course undeterred by ecclesiastical thunders, and led his army in person through the Papal States, occupying the Marches and Umbria, to Naples. On Oct. 29 he met Garibaldi, who handed over his conquests to the king. On Feb. 18, 1861, the parliament proclaimed him king of united Italy.

The next few years were occupied with preparations for the liberation of Venice, and the king corresponded with Mazzini, Klapka, Türr and other conspirators against Austria in Venetia itself, Hungary, Poland and elsewhere, keeping his activity secret even from his own ministers. The alliance with Prussia and the war with Austria of 1866, although fortune did not favour Italian arms, added Venetia to his dominions.

The Roman question yet remained unsolved, for Napoleon, although he had assisted Piedmont in 1859 and had reluctantly consented to the annexation of the central and southern provinces, and of part of the Papal States, would not permit Rome to be occupied, lest he should lose the support of the French clericals, and maintained a French garrison there to protect the pope. When war with Prussia appeared imminent Victor Emmanuel was anxious to assist the man who had helped him to expel the Austrians from Italy, but he could not do so unless Napoleon gave him a free hand in Rome. This the emperor refused to do until it was too late. Even after the first French defeats the chivalrous king, in spite of the advice of his more prudent councillors, wished to go to the rescue, and asked Thiers, the French representative who was imploring him for help, if with 100,000 Italian troops France could be saved, but Thiers could give no such assurance and Italy remained neutral. On Sept. 20, 1870, the French troops having been withdrawn, the Italian army entered Rome, and on July 2, 1871, Victor Emmanuel made his solemn entry into the Eternal City, which then became the capital of Italy.

The pope refused to recognize the new kingdom even before the occupation of Rome and the latter event rendered relations between church and state for many years extremely delicate. The king himself was anxious to be reconciled with the Vatican, but the pope, or rather his entourage, rejected all overtures, and the two sovereigns dwelt side by side in Rome until death without ever meeting. Victor Emmanuel devoted himself to his duties as a constitutional king with great conscientiousness, but he took more interest in foreign than in domestic politics and contributed not a little to improving Italy's international position. On Jan. 9, 1878, Victor Emmanuel died of fever in Rome, and was buried in the Pantheon.

Bluff, hearty, good-natured and simple in his habits, he always had a high idea of his own kingly dignity, and his really statesmanlike qualities often surprised foreign diplomats, who were deceived by his homely exterior. As a soldier he was very brave, but he did not show great qualities as a military leader. He had a great weakness for female society, and kept several mistresses; one of them, the beautiful Rosa Vercellone, he created Countess Mirafiori e Fontanafredda and married morganatically in 1869; she bore him one son.

VICTOR EMMANUEL III. (1869–), king of Italy, son of King Humbert I. and Margherita of Savoy, was born at Naples on Nov. 11, 1869. He entered the army and soon after attaining his majority, was appointed to the command of the Florence Army Corps, and in 1896 to that of the Naples Army Corps. His formal accession to the throne took place on Aug. 9 and 11, 1900, after the assassination of his father (July 29).

When in 1915 Italy declared war on Austria, the king at once went to the war zone, remaining there until the armistice, appointing his uncle Ferdinand, duke of Genoa, regent of the kingdom to act in his stead. At the front he lived in a most unassuming manner at the "Villa Italia" near Udine, and after Caporetto near Padua, constantly visiting the trenches and the most exposed positions, as well as the military hospitals, and leading to a very large extent the life of the soldiers. Although nominally commander-in-chief he never interfered with the conduct of operations, or in the matter of appointments. After Caporetto he multiplied his activities a thousand-fold, and his proclamation of Nov. 19, 1917, sounded like a trumpet-call to the whole people. After the armistice, King Victor Emmanuel returned to Rome on Nov. 14, 1918. He visited Paris and the French front with the crown prince, and subsequently London.

At the time of the Fascist march on Rome (Oct. 28–30, 1922), the prime minister, Signor Facta, intended to proclaim martial law throughout Italy, and had actually prepared the decree and communicated it to the prefects and the Press; but the king, realizing that its application would mean civil war, refused to sign it and insisted on its immediate withdrawal. After the occupation of the capital the Fascist *squadre*, before returning home, marched past the Quirinal and paid homage to the king. The advent of the Fascist Government undoubtedly strengthened the prestige of the Crown, which the troubles of 1919–22 had seriously shaken.

One of the great moments in King Victor Emmanuel's life occurred in Feb. 1929, when an enthusiastic crowd demonstrated outside the Quirinal in token of its satisfaction at the ending of the Roman Question (*see* PAPACY), and the king appeared in acknowledgment of the ovation. The Treaty with the Holy See, the Concordat and the Financial Convention are amongst the most memorable documents the king has ever signed.

Victor Emmanuel married Princess Elena of Montenegro, who bore him four daughters: Yolanda Margherita (June 1, 1901), Mafalda (Nov. 19, 1902), Giovanna (Nov. 13, 1907) and Maria (Dec. 26, 1914); and a son and heir, Umberto, prince of Piedmont (Sept. 15, 1904). Princess Yolanda was married on April 9, 1923, to Captain Count Giorhio Calvi of Bergolo, and Mafalda on Sept. 23, 1925, to Prince Philip of Hessen. A keen scholar, and especially interested in numismatics, in 1910 and 1913 he published six volumes of his monumental work on the coins of Italy, the *Corpus numnorum italicorum*, of which four more volumes appeared later. After the war Victor Emmanuel made over to the nation many royal residences in various parts of Italy. Among the most famous of these are the Pitti Palace in Florence, the villas of Castello, La Petraia and Poggio a Cajano in the neighbourhood of that city, the royal palaces of Milan, Venice, Genoa, Naples, the villa of Capodimomte near Naples, and the "Neapolitan Versailles" at Caserta. Some of these buildings were turned into hospitals and homes for war victims, and others into museums.

VICTORIA, queen of the United Kingdom of Great Britain and Ireland, empress of India (1819–1901), only child of Edward, duke of Kent, fourth son of King George III., and of Princess Victoria Mary Louisa of Saxe-Coburg-Gotha (widow of Prince Emich Karl of Leiningen, by whom she already had two children), was born at Kensington Palace on May 24, 1819. The circumstances leading up to her birth were somewhat peculiar. In 1817 Princess Charlotte, the daughter of the Prince Regent, had died in childbirth, and her death removed the only legitimate offspring of the 13 sons and daughters of George III. In order to remedy this defect three of the sons, the dukes of Clarence, Kent and

Cambridge, all of them well advanced in middle life, married in 1818. The two children of the duke of Clarence died in infancy: the duke of Cambridge had a son, also duke of Cambridge (1819–1904), Victoria's only first cousin, and for nearly 40 years commander-in-chief of the British army; but since the duke of Cambridge was younger than the duke of Kent, Victoria, christened Alexandrina Victoria, became heir to the throne.

Victoria never knew her father, for he died when she was eight months old, but his place was filled, in so far as any man could fill it, by her mother's brother, the admirable and sagacious Leopold (1790–1865). Leopold had been the husband of Princess Charlotte, and thus prospective prince consort of England. He continued to reside in the country, at Claremont, until, in 1831, he was accepted as the first king of the Belgians. The widowed mother trusted him as her best adviser, and he was responsible for the general character of the princess's education. After his removal to Belgium Victoria and Leopold carried on a close and affectionate correspondence throughout the 34 remaining years of their joint lives. After her accession (1837) the niece tactfully eluded and quickly terminated the uncle's attempts to control British policy behind the backs of the British cabinet. None the less, though she could not accept him as an extra-constitutional adviser, Victoria found, in correspondence with her uncle, a delightful outlet for her private and unofficial feelings; only to him, for example, could she speak of Palmerston and Russell as "those two dreadful old men." On his death she recorded in her Journal that he had been "ever as a father" to her.

The young princess's home was Kensington Palace, though she stayed at times with her uncle at Claremont, and frequently travelled on the Continent with her mother. Her half-sister Feodore was her nursery companion, and remained her friend until her death in 1872. When Victoria was five an admirable governess was found for her in the person of Fraülein (afterwards the Baroness) Lehzen, a native of Coburg. Louise Lehzen won the whole-hearted devotion of the princess and was the principal personal influence in her life down to her accession, at the age of 18, quite eclipsing the influence of her mother, the duchess of Kent. Victoria's relations with her mother (who lived until 1861) may be described as correct, and usually friendly, but no more. Hers is an elusive, pathetic figure. Her influence was of a negative character, yet not for that reason unimportant. She felt an intense aversion towards her brothers-in-law, George IV. and the duke of Clarence, subsequently William IV., and the feeling was fully reciprocated. Thus the little princess grew up in almost complete isolation from the surviving members of her father's family, and her accession was, as it were, the beginning of a new dynasty. With a Coburg mother, a Coburg guardian-uncle, a Coburg governess (and subsequently a Coburg husband), she always thought of herself as a member of the House of Coburg rather than the House of Hanover, a feeling which expressed itself in her disapproval of the name "George," when chosen for the grandson who was to be George V.

Victoria's upbringing and education could easily be criticized by modern standards. Until she became queen she never slept a night away from her mother's room, and she was not allowed to converse with any grown-up person, friend, tutor, or servant, without the duchess of Kent or Lehzen being present. Most will agree, however, that the education, whatever its intrinsic merits, had excellent results. Leopold considered that his niece should be kept as long as possible from a knowledge of her position; so Victoria was 12 years old before a carefully arranged history lesson revealed to her that she was to be queen. When she realized the destiny in store for her, her first words were "I will be good." Very shortly afterwards she began the detailed and highly characteristic Journal which was continued throughout her life. Selections from it, down to 1885, are included in the volumes of the Queen's *Letters*.

Accession.—William IV. died in the early hours of June 20, 1837, and the archbishop of Canterbury and the lord chamberlain, hastening with the news of the king's death to Kensington, were received by Victoria in her dressing-gown at 5 A.M. In the morning the privy council assembled at Kensington, and the usual oaths were administered to the queen by the lord chancellor. The grace and dignity of Victoria's demeanour on this occasion made an immense impression on all present. Romantic sentiment was very much in fashion, and the accession of the girl-queen carried an almost instinctive conviction to her subjects that a new, and much better, epoch in the long history of English monarchy had begun.

An important and welcome result of the accession of a female sovereign was the separation of the crowns of Great Britain and Hanover, the latter passing to William IV.'s next surviving brother, the deservedly unpopular duke of Cumberland. The separation of the two crowns was indeed even more important than could be realized at the time. Thirty years later Prussia, under Bismarck's guidance, annexed the Hanoverian kingdom. It is impossible to estimate the complications that would have arisen if the Hanoverian crown had still belonged to the British sovereign.

Melbourne.—The young queen entered with intense zest upon her new freedom, her new interests and her new duties. "I have," she wrote, "*so many* communications from the Ministers, and from me to them, and I get so many papers to sign every day, that I have always a *very great* deal to do. I *delight* in this work." After 18 years of seclusion, zealously supervised by the duchess and Lehzen, with scarcely any male society except Uncle Leopold and sundry tutors, it was a delight to do business with the great men of the land. But all other great men were eclipsed in her eyes by her prime minister, Lord Melbourne. The story of that romantic friendship has often been told. The queen had necessarily much to learn about the elements of domestic and foreign policy, and the art and tact of Melbourne made such lessons a pleasure. But the statesman's unlimited influence was not in all respects wisely used. Himself the leader of the Whig party, he surrounded the queen with Whig ladies, and allowed her to become an enthusiastic partizan of the Whig party. The duchess of Kent had been rigorously excluded from all share in the queen's political duties. A spiteful rivalry arose between the ladies of the duchess and of the queen, culminating in baseless accusations of immoral conduct against Lady Flora Hastings, a maid of honour to the duchess of Kent. Before the first year of the reign was over the queen's court, had, temporarily, sunk low in the esteem of high society, and it is impossible to believe that Melbourne could not, with more vigilance, have prevented these scandals. The loyalty of the nation as a whole, however, was probably unimpaired, and the coronation ceremony, on June 28, 1838, with the royal procession through the streets of London, provided an impressive demonstration of that loyalty.

In May 1839 Lord Melbourne resigned, and Sir Robert Peel, the Conservative leader, stipulated that the mistress of the robes and the ladies of the bedchamber appointed by his predecessor should be removed. The queen refused. Lord Melbourne urged her to give way, but he could not undo in a minute the results of his own work, and, when Peel had refused to take office with the ladies unchanged, Melbourne very weakly consented to resume office. The next few months witnessed Chartist riots and demonstrations more extensive than any before or afterwards, and denunciation of the queen's conduct was a popular item in Chartist propaganda.

In certain other respects the queen's manner of life during these first years of her reign was in marked contrast with what was to follow. She preferred the gaiety of the town to the peace of the country, delighted in social festivities and late hours, and even rebuked those whose judgments of others seemed to her over-strict and puritanical. Long afterwards she wrote to Mr. Theodore Martin, the author of the *Life of the Prince Consort*:—"The Queen's letters between '37 and '40 are *not* pleasing, and indeed rather painful to herself. It was the least sensible and satisfactory time in her whole life. . . . That life of mere amusement, flattery, excitement, and mere politics, had a bad effect on her *naturally* simple and serious nature. But *all* changed after '40."

1840–1861

Marriage.—It had long been Leopold's design that Victoria should marry his nephew Prince Albert, son of the duke of Saxe-Coburg-Gotha. Albert, who was the same age as Victoria, had visited her before her accession, and had since been carefully coached for his prospective career by Baron Stockmar. Stockmar was one of the most important and least conspicuous figures of 19th century history. Originally a doctor of medicine, he had long been the intimate adviser of Leopold, and he was now to be transferred to the service of Albert. He was very able, with an ambition which found its sole satisfaction in securing the greatness of his successive masters. It has been said with little exaggeration that Albert was "Stockmar's creation," and one may add that Victoria as revealed from 1840 onwards was the creation of Albert. During the Melbourne ascendancy the queen had rather alarmingly declared that she did not see why she should ever marry, but when Albert arrived on a visit in Oct. 1839, Victoria capitulated at once, and the engagement was announced. The marriage was solemnized on Feb. 10, 1840, the queen being dressed entirely in articles of British manufacture.

The task confronting Albert as husband of the British queen was no simple one. His position was virtually without precedent, for Queen Anne's husband had been content with his nonentity, Queen Elizabeth had not married, and Queen Mary had married the ruler of a foreign country who only occasionally visited her. Moreover Albert's character was not of a kind to recommend him either to the British aristocracy or to the nation. He was stiff and shy, studious, laborious, pedantic and exact, entirely indifferent to "sport." At first the queen herself was the greatest of his difficulties, for in spite of her personal devotion she was determined to exclude him as rigorously from political affairs as she had already excluded her mother. Melbourne was her sole partner in public life; Lehzen, the promoted governess, was supreme over the royal household; nothing apparently remained for Albert but to be the father of her children. But, with Stockmar at his elbow, he made his way. Melbourne was dismissed by the general election of 1841. Victoria's prejudice against Peel gave Albert his opportunity, and he negotiated a satisfactory compromise on the "Bedchamber" question. Peel, with his earnest middle-class temperament, was to Albert a comparatively congenial spirit, and Victoria soon learnt to like him. Albert became the queen's partner in politics, and, being her superior in intellect and knowledge, became inevitably her master and guide. Lehzen returned to her native Germany. Meantime the queen had become a mother. The "Victorian Age" had begun in earnest.

It will be convenient to summarize at once the growth of the royal family. The Princess Royal (the "Vicky" of the *Letters*) was born in November 1840; in 1858 she married the crown prince of Prussia and was the mother of the Emperor William II. The prince of Wales (Edward VII.) was born in 1841. There followed Princess Alice, afterwards grand duchess of Hesse, 1843; Prince Alfred, afterwards duke of Edinburgh and duke of Saxe-Coburg-Gotha, 1844; Princess Helena (Princess Christian), 1846; Princess Louise (duchess of Argyll), 1848; Prince Arthur (duke of Connaught), 1850; Prince Leopold (duke of Albany), 1853; Princess Beatrice (Princess Henry of Battenburg), 1857. The queen's first grandchild was born in 1859 and her first great-grandchild in 1879. There were 37 great-grandchildren alive at the time of her death.

The growing cares and joys of family life combined with the influence of Albert to produce a complete change in the queen's habits. Gone was the love of idle splendour and "mere amusement." The early 'forties were the "hungry 'forties," and Victoria expressed to Peel a desire to cut down the expenses of the court in order to give more of her income to charity. Sir Robert discouraged an impulse which seemed to him all too human. "I am afraid the people would only say," he replied, "that Your Majesty was returning them change for their pounds in halfpence." A sovereign, he said, must do all things in order, not seeking praise for doing one particular thing well, but striving to be an example in all respects, even in the giving of dinner-parties. The dinner-parties of the royal pair were indeed a conspicuous example of decorum, but the guests found them stiff and by no means amusing. At the same time it should be said that the young queen's dignity and discretion made a great impression upon the royal visitors from abroad. Among such in the first ten years of her married life were Frederick William IV. of Prussia, Louis-Philippe of France, and the Tsar Nicholas I.

Osborne and Balmoral.—In June 1842 the queen made her first railway journey (though railways had been in use for some 12 years), travelling from Windsor to Paddington. The Master of the Horse, whose business it was to provide for the queen's journeys, was much put out by this innovation. He visited the station and inspected the engine several hours before it was due to start; and when the journey was about to begin the queen's coachman insisted on mounting the engine and presiding over its manipulation. It is said that his scarlet livery got so much soiled on the journey that he did not insist upon repeating the experiment. A few weeks later the queen used the railway for her first journey to Scotland. Railway travel, the most characteristic innovation of the queen's reign, made an important contribution to her happiness, for it enabled her, without losing contact with her ministers, to reside for long periods of each year in the country houses she built for herself at Osborne in the Isle of Wight, and at Balmoral in the Highlands of Scotland. Politicians sometimes complained, not without reason, of the labours and delays occasioned by the queen's addiction to these resorts, especially to the distant Balmoral; but at a later period the delays of correspondence were reduced by another innovation, the telegraph. Telegraphic communication was established between London and Balmoral in the early 'sixties. At the same time, it was usually expected that members of the Cabinet should take turns in "doing service," as Lord Palmerston called it, of residence with the queen when at Balmoral.

The estate at Osborne was purchased by Peel's advice, and the residence built, in 1846, out of the queen's savings from her income. The lease of the original (and quite small) Balmoral House was taken two years later. In 1852 the estate was bought, and the great palace in "Scotch baronial" style completed in 1855. At Balmoral her happiest days were spent. "Every year," she wrote, "my heart becomes more fixed in this dear Paradise, and so much more so now, that *all* has become my dear Albert's *own* creation, own work, own building, own laying-out;—and his great taste, and the impress of his dear hand, have been stamped everywhere." The queen held the Highlanders in more esteem than any other section of her subjects. Her favourite servant, the Highlander John Brown, was her inseparable attendant down to his death in 1883. Protestant to the core, she felt a more entire sympathy with the Presbyterian Established Church of Scotland than with the English Church. It is probable that she esteemed no English minister of religion so highly as the Scottish Presbyterian, Norman MacLeod. When he died in 1872 she wrote:—"There was in beloved Norman MacLeod such geniality with true piety, and the *strongest belief*, the largest, widest Christian love . . ." ending with the words, "he was a thorough Highlander."

The Great Exhibition of 1851 belongs to the career of Albert rather than Victoria. The old Houses of Parliament had been burnt down and the problems connected with the building of the new Houses suggested to Peel the desirability of a royal commission to consider the best means of promoting the arts and sciences. He invited Albert to preside over the commission, and its work suggested to the prince the idea of the Exhibition. That Exhibition, the first of its kind, held in the Crystal Palace erected in Hyde Park, owed everything to Albert's organizing energy. The work of the commission led to the creation of the Museum and the Science and Art Department at South Kensington, and to the founding of art schools and picture galleries all over the country.

Conflicts with Palmerston.—The fall of Peel in 1846 and the return of the Whigs brought Lord Palmerston to the Foreign Office and led to the severest struggle between the Crown and its ministers since the day when George III. had dismissed the Coalition of Fox and North in 1783. Palmerston had passed his

60th birthday and could look back on a career of high office which began ten years before the royal couple were born. Confident in his parliamentary skill and in his capacity to solve every problem of foreign policy on the spur of the moment, shrewd, bold, instinctive, casual, contemptuous of foreign potentates and diplomatic amenities, he was in every respect the antithesis of Albert. Albert distrusted Palmerston's character, disapproved of his methods, disliked his policy, and, prompted by Stockmar, disagreed with his conception of the British constitution. In the contests that ensued Victoria was the disciple of Albert, a disciple whose zeal and vehemence outran that of her husband and master; for Albert was never vehement. The fundamental issue was the interpretation of the British constitution—a constitution notoriously flexible and elusive. Lord Clarendon, after dining with the royal pair at the height of the conflict, declared that they "laboured under the curious mistake that the Foreign Office was their peculiar department, and that they had the right to control, if not to direct, the foreign policy of England."

It is impossible here to follow the struggle through all its phases. Suffice it to say that the royal pair secured an ally in the prime minister, Lord John Russell, himself, for Palmerston often treated his colleagues as casually as he treated the sovereign, and took important decisions and sent off important despatches without consulting either the one or the other. In 1850 the queen delivered a kind of ultimatum in the form of a memorandum drawn up for her use by Stockmar. "With reference to the conversation about Lord Palmerston which the queen had with Lord John Russell the other day, and Lord Palmerston's disavowal that he ever intended any disrespect to her by the various neglects of which she has had so long and so often to complain, she thinks it right, in order to avoid any mistakes for the future, to explain what it is she expects from the foreign secretary. She requires: (1) That he will distinctly state what he proposes in a given case, in order that the queen may know as distinctly to what she has given her royal sanction; (2) Having once given her sanction to a measure, that it be not arbitrarily altered or modified by the minister." Lord Palmerston accepted the rebuke with apparent meekness, but his conduct continued unchanged. At the end of 1851 he expressed to the French ambassador, without having consulted either Russell or the queen, his approval of Napoleon's *coup d'état*. Russell immediately dismissed him and used the occasion to make public the queen's memorandum quoted above. But in a few months Palmerston secured his "tit for tat" by overthrowing Russell's administration.

It was unfortunate for Victoria and Albert that Palmerston was the most popular statesman in the country. At the beginning of 1854, when the country was visibly drifting into the Crimean War, it was announced that Palmerston (at that date home secretary in Aberdeen's coalition Government) had resigned office. At once an extraordinary storm of popular fury burst forth against the royal pair whose machinations, it was supposed, guided by the hidden hand of the alien Stockmar, had brought about the downfall of the one statesman in whom the nation felt confidence. There were rumours that both the queen and the prince had been committed to the Tower. "Thousands of people," wrote Albert to Stockmar, "surrounded the Tower to see the Queen and me brought to it." It was supposed that Albert was in the pay of the Russians. Palmerston's resignation was, however, withdrawn, and the gross absurdity of the charges brought against the prince, coupled with the unmistakable patriotism of his conduct throughout the war, produced a marked revival of royalist sentiment. The queen personally superintended the committees of ladies who organized relief for the wounded, and eagerly seconded the efforts of Florence Nightingale; she visited crippled soldiers in the hospitals, and instituted the Victoria Cross. The alliance with France led to a visit from the French emperor, whom the queen found very attractive, and in 1856 the visit was returned, this being the first occasion that a British sovereign had visited Paris since the coronation of Henry VI. in the days of Joan of Arc.

The Crimean War made Palmerston prime minister, and he retained the office, with one short interval, until his death in 1865. From 1859 onwards Russell was foreign secretary and his conduct was not found much more satisfactory than that of Palmerston. Palmerston and Russell supported, while Victoria and Albert disliked, the actions of Cavour and Garibaldi which led to the union of Italy. In 1861 the American Civil War broke out. A vessel of the "Northern" navy improperly arrested two "Southern" envoys on a British steamer, and a typically unwise and peremptory despatch of Russell's might have involved Great Britain in an unforgivable war with Lincoln's Government, had not Albert secured its alteration. It was the last act of his life. His health had long been unsatisfactory and his spirits depressed. His constitution, never robust, was undermined by overwork and political adversity. At the end of 1861 he was smitten with what was probably typhoid fever and died on Dec. 14.

1862–1901

Widowhood.—Victoria was only 42 at the date of her tragic bereavement; 39 years of life remained to her, nearly half her life, and much more than half her reign. The queen's life during her long widowhood lacks the variety of the earlier years; crowded with events it may in a sense be said to be, but those events are the political history of the nation and empire over which Victoria was called to rule, and it is no easy task to disentangle biography from history. Yet it is on this latter part of the queen's life that a judgment of her character and statesmanship should be principally founded. Until her marriage she had been little more than a child; during her married life she had accepted wholeheartedly the guidance of her adored husband; after 1861 she stood alone and, ably as she was served by a succession of devoted secretaries, her conception of her duties and her policy was her own. "I am *determined*," she wrote to her uncle Leopold, "that *no one* person—may *he* be ever so good or ever so devoted among my servants—is to lead or guide or dictate *to me*. I know *how he* would disapprove of it. . . . Though miserably weak and utterly shattered, my spirit rises when I think *any* wish or plan of his is to be touched or changed, or I am to be *made to do* anything."

There were many, and among them both the editor of the *Times* and the prime minister, Lord Palmerston, who assumed that the prince of Wales, who was already somewhat older than his mother had been at her accession, would be admitted, either at once or by degrees, to a partnership with the queen like that which her husband had enjoyed. But Victoria would have none of it. Though she groaned under the labours of her self-imposed isolation, and expressed again and again a longing for a release from them by death, she rigidly excluded her heir from all share in her political duties, and maintained that exclusion to the end. Perhaps if "Bertie" (as he was always called in the family) had been more like Albert, her decision might have been otherwise, and the lives of both mother and son, we cannot doubt, would have been happier. But the prince was of a Hanoverian rather than a Coburg type. He had not proved amenable to the education so carefully provided for him. He might have ideas of his own, and Victoria was determined that the royal policy should continue to be Albert's and that she alone knew what that policy would be.

It is impossible to exaggerate the grief of the widowed queen. Other women have loved their husbands as dearly, but not all, nor perhaps many, of these have experienced so long and so poignantly what Tennyson, Victoria's favourite poet, called "sorrow's crown of sorrow," the continued overshadowing of the present by the never-forgotten brightness of the past. The queen's mourning, alike in form and in fact, was indefinitely prolonged. Never again would she, to the end of her days, take up her residence in London. Only seven times, and then as a rule with much protest and complaining, did she consent to undertake the ceremonial duty of opening the parliamentary session. Up to the time of the first Jubilee the public and spectacular functions of royalty remained almost entirely in abeyance, except in so far as they could be, and were, performed by the prince and princess of Wales. It was inevitable that this should cause dissatisfaction. There were suggestions, in the 'sixties, that the queen should abdicate in favour of her son. In the early 'seventies two rising politicians, Joseph Chamberlain and Sir Charles Dilke, were

reputed to be "republicans," and the queen's failure to use her large income for what was supposed to be its proper purpose, was acrimoniously criticised. Victoria bitterly resented such complaints. Her physicians agreed that her health could not stand the strain of public ceremonies, and she held that she was discharging with unremitting industry the essential, as distinct from the ornamental, duties of her office. The modern notion that politics should be left to politicians had never been accepted by even the most lethargic of her predecessors, and it certainly found no favour with Victoria.

The Constitutional Monarch.—In his treatise on *The English Constitution* (published 1865) Bagehot said that the sovereign had, in relation to his ministers, three rights—the right to be consulted, the right to encourage, and the right to warn; and, he adds, a sovereign of great sense and sagacity would want no others. "He would find that his having no others would enable him to use these with singular effect." If the sovereign disapproved of the minister's policy "he might not always turn his course, but he would always trouble his mind. In the course of a long reign a sagacious king would acquire an experience with which few ministers could contend." Moreover the sovereign's position must give him imponderable advantages in any conflict of opinion with his ministers. For there is a "divinity which doth hedge a king," and the minister, as Bagehot quaintly puts it, "cannot argue on his knees."

Victoria had learnt from her husband and her uncle Leopold to have a low opinion of the intelligence, industry and patriotism of politicians in general and English politicians in particular. She conceived it to be her duty to do all that lay within her power to save her people—for were they not *her* people?—from the disasters into which their elected representatives were only too likely to lead them. She exercised to the full her "right to be consulted." Again and again, as we turn the pages of the *Letters of Queen Victoria* (*1862–85*), we find ministers reprimanded for making decisions without first submitting them to the queen. The ministers humbly apologise, plead haste, or accident, or suggest that the decision in question had in fact already been in principle approved, and promise not to offend again,—a promise seldom fulfilled, it would appear. The duties of ministers in this respect were indeed not easy, for in politics, especially foreign policy which was the queen's principal interest, speed is often an essential ingredient of efficiency, and the queen's absence at Balmoral or Osborne (she spent about four months of every year at each of these residences) made royal consultation difficult. In her exercise of "the right to encourage," the queen was more sparing, though she gave generous commendation where she felt that commendation was deserved; but only an exceptional statesman—a Disraeli for example—won that affectionate confidence which the queen gave so readily to all her leading soldiers and to some of her representatives abroad, Lord Odo Russell, for example, when ambassador at Berlin, and Lord Lytton when Viceroy of India. The third of the rights enumerated by Bagehot, "the right to warn" was exercised without any intermission whatever. Again and again the queen exerted all her resources to secure a reversal of the policy adopted by her ministers. In small matters often and in great matters sometimes she succeeded. But when she found that no warnings of hers, however vehement, would avail, she remembered the limitations of her power, and officially identified herself with the policy she personally detested.

England and Germany.—For the first four years of the queen's widowhood (1862–65) Lord Palmerston, now nearly 80, was prime minister, with Russell, already past 70, as his foreign secretary, and the most embarrassing question of the day was the notorious "Schleswig-Holstein question" (*q.v.*). Roughly speaking, the question at issue was whether these two duchies, with their mainly German population, should remain subject to the king of Denmark, or become a separate state under a German prince, or be annexed by Prussia. In the English press and public there was widespread sympathy for Denmark, strengthened by the marriage, in 1863, of the prince of Wales with the charming Danish princess who was subsequently Queen Alexandra. Palmerston and Russell were strongly pro-Danish, and might well, in defiance of the views of the rest of the cabinet, have plunged the country into a disastrous war. The queen played an all-important part in restraining "those two dreadful old men." Her sympathies were with Prussia. Her eldest daughter had married the Prussian crown prince, and Albert had always held that the German States ought ultimately to be united under the Prussian monarchy. Within two months of the death of her husband she was at work, insisting on the removal of a provocative phrase from a despatch to Prussia. In her long struggle with Russell and Palmerston she was maintaining the rights of the cabinet as well as the prerogatives of the Crown, and her efforts were crowned with the success they deserved.

But the Prussia now in the ascendant was not the Prussia to which Albert had given his blessing. Bismarck was in power, and for Victoria he was henceforth and always a "terrible man." The war of 1866, when the Prussian armies engaged and defeated in six weeks the forces of Austria and all the German States, was a bitter grief to the queen, who had near relations fighting on both sides. Her personal offer of mediation before the conflict had been rudely brushed aside. In 1870 the clever camouflage of Bismarck's diplomacy and an almost instinctive distrust of the French made her once more a whole-hearted partisan of Prussia. But when the victory of Prussia had been assured the queen exerted herself to save Paris from bombardment, and Bismarck himself furnished evidence of her success, when he complained that "the petticoat sentimentality" with which Victoria had infected the Prussian royal family hampered the designs of the Prussian army. Victoria looked forward to the day when her son-in-law would succeed to the Prussian throne, dismiss Bismarck, and direct the new German empire into liberal and humane courses. But it was not to be. Bismarck's emperor lived to be 91; the crown prince reigned but 100 days (in 1888); and William II. accepted all that was worst, while rejecting most of what was wisest, in the policy of Bismarck. Only once, in 1888, did Victoria engage in direct encounter with "the terrible man." Her grand-daughter, a daughter of the German crown prince, was engaged to Prince Alexander of Battenburg (Prince of Bulgaria) and Bismarck was determined to prevent the match. Bismarck claimed a personal interview with Victoria, and the marriage had to be abandoned.

Franchise Reform.—After the death of Palmerston (1865) his successor Lord Russell revived the question of an extension of the franchise beyond the "middle-class" limits fixed in 1832. The Russell-Gladstone Bill was rejected; the Government resigned, and the Hyde Park riots followed. The queen had little or no personal interest in such questions but she had a horror of demonstrations of popular discontent, which she always feared might ultimately take a republican direction, and she took an early opportunity of writing to her new prime minister, the Conservative Lord Derby, urging him to take up the question in earnest and achieve its settlement, and promising to do all in her power to secure the co-operation of the Leaders of the Opposition. The result was the famous Second Reform Bill of 1867, so skilfully piloted through the House of Commons by Disraeli. It is probable, no doubt, that the Conservative Government would in any case have pursued a similar policy, for the same ministers had done so, unsuccessfully, in 1858. None the less the queen's action is one of many examples that could be adduced to show that she was not, in domestic affairs, a supporter of a policy of standing still. On certain domestic questions, such as Housing, she was well in advance of most of the politicians of her day, and posterity will endorse her remark that the clearance of slums was more worthy of attention than a great many of the subjects with which 19th century parliaments occupied their time.

Ireland.—The years 1867–68 were marked by the destructive outrages of the Fenians. Victoria characteristically refused to take the precautions for her personal safety which her ministers urged upon her. Both political parties turned their attention perforce to Irish grievances, and Gladstone won a decisive victory in the election of 1868 with a programme in which the main item was the disestablishment of the Irish Church. From 1868–74 he was her prime minister.

Victoria's attitude towards Ireland was much the same as that of a great many of her English subjects. She had little understanding of or sympathy with Irish grievances, and the demand for Home Rule, now beginning to be vocal in the House of Commons, she regarded as sheer disloyalty. It had been suggested that she should establish a "Balmoral" in Ireland, but the idea was repugnant to her. The Irish climate was "unhealthy," and being a bad sailor she detested the crossing. Perhaps the prince of Wales might establish a residence there? No; he would only be able to reside there very occasionally, and the upkeep of the house would not be worth its expense. On the other hand the queen was always intensely appreciative of the bravery of her Irish regiments, and their gallantry in South Africa led her to make, in 1900, a three weeks' visit to Dublin which was one of the last public actions of her life.

Gladstone and Disraeli.—The queen felt a strong repugnance towards Gladstone's policy of disestablishing and partially disendowing the Irish Protestant Church. She regarded it as a diminution of her own prerogatives and as a concession to popery, nor were her feelings assuaged by the document which Gladstone presented to her as an exposition of the measure, for she found it entirely incomprehensible. None the less she recognized that the electorate had spoken decisively, and that the bill must be passed. Her attention turned to the House of Lords. Gladstone's policy threatened to produce, for the first time since the "Great" Reform Bill, a serious conflict between the two Houses, and such a conflict she regarded as endangering the whole fabric of the constitution, and opening the way to "democracy" and republicanism; that the monarchy could survive in a completely democratized State Victoria never believed. Her chosen instrument in securing a compromise between the Houses was Archbishop Tait, and Gladstone seconded her efforts by timely concessions on the disendowment clauses.

Equally distasteful to the queen were the Army reforms of Cardwell, but here again, realizing that the reforms could not be resisted, she worked hard for their smooth passage, exerting a moderating influence on her cousin, the duke of Cambridge, who was commander-in-chief. The abolition of the system of purchase of commissions, rejected by the House of Lords, was achieved over their heads by royal warrant.

Disraeli's accession to office in 1874 opened what was for the queen a far happier period. There had been a time, in the far-off days of Corn Law Repeal, when Victoria and Albert had regarded Disraeli as the most detestable of all politicians, but as soon as Disraeli became leader of the House of Commons, in 1852, he began to obliterate those memories. "Mr. Disraeli," she had written to her uncle Leopold, "writes very curious reports to me of the proceedings of the House of Commons—much in the style of his books." It was a style that the queen came rapidly to appreciate. Disraeli's brief prime ministership in 1868 had greatly advanced him in royal favour. Never, since the death of Prince Albert, had her political duties been made so easy and so interesting. None of her prime ministers realized as Disraeli realized that, when a queen is on the throne, the successful prime minister must be a perfect courtier. No one could have surpassed Gladstone in his reverence for the throne, but that reverence expressed itself in a solemn and pompous abasement: Disraeli's homage to the throne was expressed as personal devotion to the lonely and essentially simple-minded woman who was its occupant.

The new prime minister's vigorous imperial and foreign policy was entirely congenial to the queen, who warmly applauded the acquisition of the Suez Canal shares, and welcomed the measure which conferred upon her the title of empress of India (1876), but she was by no means inclined to relax the vigilance of her control over ministerial policy. The prolonged Balkan crisis and the Russo-Turkish war of 1877–78 excited her passionate interest, and though she trusted Lord Beaconsfield (as he had now become), she had the very lowest opinion of his foreign secretary, Lord Derby (son of the former prime minister). "The Queen writes every day and telegraphs every hour," wrote Beaconsfield to his confidant, Lady Bradford. If Victoria had had her way in 1877, Great Britain would probably have undertaken another war with Russia, as unprofitable as the Crimean War.

The election of 1880 brought Gladstone back to power and ushered in what were to be the most harassing years, from a political standpoint, of the queen's reign. Her antipathy to Gladstone had been deepened by his conduct in opposition. Gladstone had denounced Beaconsfield's reckless imperial ventures in Afghanistan and South Africa and his support of the blood-stained Turk against Russia as something worse than mere errors of policy. He had held them up to reprobation as iniquitous, and the queen, identifying herself with Beaconsfield's policy, regarded Gladstone's speeches as something like personal insults to herself. Gladstone had nominally resigned the leadership of the Liberal party in 1874, and Victoria tried to avail herself of this fact to construct a Liberal administration under Granville or Hartington, from which Gladstone should be excluded; but it was impossible.

The Liberal Government of 1880–85 was one of the most unfortunate in British history; it was the Government of Majuba, the Phoenix Park murders, and the fall of Khartoum. Space does not allow us to examine the complicated and tragic record, nor is it here appropriate either to condemn or to acquit the Government on the various charges that have been brought against it. The queen's letters during these years make extremely distressing reading. She distrusted her prime minister and found little that was good in many of his colleagues. Lord Granville at the foreign office was "as weak as water"; Chamberlain was constantly uttering sentiments which, the queen held, should have excluded him from any cabinet. The "right to warn" was lavishly employed, yet it would seem, did not influence ministers. Almost inevitably a tone of peevishness and, as one might say, of "nagging" becomes more and more apparent. Even on the rare occasions when the ministers gained the queen's approval, her commendation is seasoned by the taunt that what they are now doing might well have been done before. The rôle of a constitutional monarch as Victoria understood it becomes well-nigh impossible, when the gulf between the monarch's and the ministry's policy is of more than a very moderate width, and the result is bad for all concerned; for the sovereign becomes one of the ministry's principal embarrassments, and a hypothetically bad ministry is more likely to be made worse than better by continuous royal badgering.

The Jubilee Period.—But for the queen the worst was very nearly over. After the election of 1885 Gladstone adopted a policy of Home Rule, and a section of his own party joined with the Conservatives in defeating the Home Rule Bill of 1886. Henceforth, with a brief Gladstonian interval in the early 'nineties, the Conservatives, under Salisbury, were in power. Imperialism after the queen's own heart became more and more the national mood. Before her death she saw the more deplorable of Gladstone's withdrawals reversed, with Kitchener at Khartoum and Roberts at Pretoria. A sunlit and glorious evening came to greet the end of her long laborious day. Gladstonian Liberalism was on the wane; Socialism had not yet made effective entry into politics. After the acute industrial distress of the early 'eighties a period of unprecedented material prosperity set in—the "Jubilee period." The end of a century was approaching, and the end of an age, the Victorian Age. In the Jubilees of 1887 and 1897 the queen was accepted as the worthiest symbol of a great nation and an unparalleled empire. The end came in the first month of the new century, after a brief and painless illness. It was by four years the longest reign, and by three days the longest royal life, in British history.

Church Patronage.—The queen took a keen interest in appointments to vacant bishoprics, and undoubtedly valued as highly as Queen Elizabeth had done her position as the Head of the Established Church. She was herself deeply religious and her preference was for what would now be regarded as a somewhat old-fashioned type of Protestant piety, but her views on the exercise of her patronage were well abreast of the times. The foes of the Establishment and of true religion, in her judgment, were agnosticism and the "ritualism" of the Anglo-Catholic movement; it is, she wrote to Disraeli in 1875, "of the utmost importance that really intellectual, liberal-minded, and courageous men should

be appointed." The "materialistic tendencies" of the age could not be checked by "evangelical trash." Two years later we find her writing, "Unbelief can only be met by a full recognition of the rights of reason and science." Her preference was for Broad Churchmen, and perhaps the most important ecclesiastical appointment of her reign, that of Tait to the Archbishopric of Canterbury, was her personal choice forced upon a reluctant prime minister. Her most trusted adviser in ecclesiastical matters was Dean Wellesley of Windsor, and after his death in 1882 she relied much on his successor, Dr. Randall Davidson, subsequently archbishop of Canterbury. It is characteristic of her eminent fairness of mind that she scrutinised with considerable suspicion the ecclesiastical recommendations of Disraeli, rebuking his attempts to use church preferment for the promotion of supposed Conservative interests, whereas she treated with far greater respect the recommendations of Gladstone who, whatever his political delinquencies, could never be accused of sacrificing the interests of the Church to those of his party.

The Empire.—Much might be said of the queen's pride and interest in the peoples of her far-flung empire. India was always near her heart and she encouraged her viceroys to write her long personal letters. In her later years she had a devoted Indian personal servant, and amused herself with learning the elements of Hindustani. The queen's devotion to her Indian subjects was amply appreciated and returned, alike by the chiefs and by the common people. Sir W. R. Lawrence writes (1928) in his book *The India we Served*:—"From my verandah in the early morning of Feb. 2, 1901, I saw a sight which set me thinking. I saw the greater part of Calcutta's dense population file solemnly past on their way to the great park (Maidan) to sit there all day, without food, mourning for the great Queen-Empress who had made them her children."

In 1863 we find her describing in her Journal with obvious relish the visit of certain Maori chieftains. "They all kissed my hand and behaved extremely well." On a later occasion the visitor was the redoubtable Cetewayo, and the queen's only regret was that he did not appear in his native costume, though there was apparently very little of it. In 1874 she conveyed, through her friend Dean Stanley, to Bishop Colenso of Natal, her warm approval of his championship of the rights of a native chief against the oppressive policy of the Natal Government. An amusing example of her good sense was afforded by the annexation of Fiji at the same date. Cabinet ministers agreed in finding this name "barbarous and unpleasing"; one suggested "the New Orkneys," another "Oceania," and Disraeli favoured "the Windsor Islands." Victoria held that "Fiji" was quite good enough, and Fiji it remains to this day.

The Queen's Achievement.—The essential achievement of the great queen is plain for all to see: it is massive in its simplicity. She received a crown that had been tarnished by ineptitude and vice; she wore it 63 years, and made it the symbol of private virtue and public honour. If a monarchy at once dignified and popular is of value to the nation and empire, then it was Victoria who gave back these long lost values to the crown. The achievement was one of character much more than of intellect. Opinions will differ as to the queen's political acumen, and as to the soundness of her interpretation of her duty towards her ministers. No one can question the intensity of her devotion to her duty, as wife, mother, and queen, nor the transparent honesty of her character. There are degrees of honesty even among honest men, and the queen's honesty was of the highest degree. After all, the two best things in the world, perhaps, are hard work and a happy family life, and the queen presented to her subjects a shining example of both. Her personal sympathies extended beyond her family to all her servants, and the humblest could always be the most sure of her sympathies. On occasions of mourning the queen's message was something more than royal; it it was spoken from the heart of a widowed woman. When, five weeks after her husband's death, there was a bad colliery disaster at Hartley, the queen commanded her secretary to write:—"Her tenderest sympathy is with the poor widows and mothers; her own misery only makes her feel the more for them." It is but one example of many.

Perhaps a fit conclusion would be a prayer from the queen's Journal, one of many; it is dated Jan. 1, 1878. "May this year bring us peace, and may I be able to maintain strongly and stoutly the honour and dignity of my dear country! . . . God help me on in my arduous task!"

The most important authority for the queen's life is the two series of *Letters of Queen Victoria, 1837–1861* (1907), and *1862–1885* (1926–27). There is an excellent popular life by Lytton Strachey (1921) and a detailed biographical article by Sidney Lee in the *Dictionary of National Biography*, to which a full bibliography is appended.

(D. C. So.)

VICTORIA (or VITTORIA), **TOMMASSO LUDOVICO DA** (*c.* 1540–*c.* 1613), Spanish musical composer, was born probably at Avila. In 1573 he was appointed as Maestro di Cappella to the Collegium Germanicum at Rome, where he had probably been trained. Victoria left Rome in 1589, being then appointed vice-master of the Royal Chapel at Madrid, a post which he held until 1602. In 1603 he composed for the funeral of the empress Maria the greatest requiem of the Golden Age, which is his last known work, though in 1613 a contemporary speaks of him as still living. He was not ostensibly Palestrina's pupil; but Palestrina had the main influence upon his art, and alike personally and artistically the relations of the two were close. The work begun by Morales and perfected by Palestrina left no stumbling-blocks in Victoria's path and he was able from the outset to express the purity of his ideals of religious music without having to sift the good from the bad in that Flemish tradition which had entangled Palestrina's path while it enlarged his style. From Victoria's first publication in 1572 to his last requiem (the *Officium Defunctorum* of 1605) there is practically no change of style, all being pure church music of unswerving loftiness and showing no inequality except in concentration of thought. Like his countryman and predecessor Morales, he devoted himself entirely to sacred music; yet he differs from Morales, perhaps more than can be accounted for by his later date, in that his devotional spirit is impulsive rather than ascetic. He strikes the note of aspiration rather than that of renunciation.

Victoria's work is the crown of Spanish music: music which has been regarded as not constituting a special school, since it absorbed itself so thoroughly in the Rome of Palestrina. In any extensive anthology of liturgical polyphony such as the *Musica Divina* of Proske, his work stands out as impressively as Palestrina's and Lasso's; and the style, in spite of a resemblance to Palestrina which amounts to imitation, is as individual as only a successful imitator of Palestrina can be. That is to say, Victoria's individuality is strong enough to assert itself by the very act of following Palestrina's path. When he is below his best his style does not become crabbed or harsh, but over-facile and thin, though never failing in euphony. If he seldom displays an elaborate technique it is not because he conceals it, or lacks it. His mastery is unfailing, but his methods are those of direct emotional effect; and the intellectual qualities that strengthen and deepen this emotion are themselves innate and not sought out. The emotion is reasonable and lofty, not because he has trained himself to think correctly, but because he does not know that any one can think otherwise.

His works fill eight volumes in the complete edition of Breitkopf and Härtel.

(D. F. T.)

VICTORIA, a State of the Commonwealth of Australia occupying a triangular area of *c.* 88,000 sq.m. (56,245,760 ac.) in the extreme south-east of the continent of which it forms roughly a thirty-fourth part. After Tasmania it is the smallest Australian State, and is marked off from New South Wales on the north by the river Murray from near its source to the South Australian border and by a straight boundary line drawn from The Springs, on Forest Hill near the Murray source, east-south-east to Cape Howe. On the west its border marches, along long. 140° 58′ E., with that of South Australia for some 250 m. (*i.e.*, from the Murray to Discovery bay near the mouth of the river Glenelg) and on the south a coast-line of *c.* 680 miles extends, with some marked irregularities, in an east-west direction from Discovery bay to Cape Howe (long. 150° E.) and faces Bass strait, the Southern and Pacific oceans and Tasmania. Its most northerly

portion lies in the north-east at *c.* lat. 34° S. and its coast-line lies approximately along lat. 38° 30′ S. (Wilson's promontory, the most southerly point of Australia: lat. 39° 8′ S.) and in respect of size, climatic conditions and general economic development it shows certain marked resemblances to, and also significant differences from, the British Isles (*c.* 88,756 sq.m.; *v. inf.*).

Physiography.—Geological structure and surface configuration mark out the area into four main divisions: (*a*) A "backbone" of highlands, styled somewhat misleadingly in view of its breadth the "Great Dividing Range." It falls into an eastern and a western section, the line of division corresponding approximately with the Kilmore Gap (*c.* 1,145 ft.) north of Melbourne. The eastern section comprises the massive but broken plateau of the Australian Alps (*q.v.*), which forms part of the main eastern highland belt of Australia. (*See* AUSTRALIA: *Geomorphology;* also NEW SOUTH WALES and TASMANIA: *Physiography.*) From its granite and basalt surfaces blunted elevations such as Mounts Cobboras (Bowen Mtns.), Feathertop, Hotham, Bogong rise to over 6,000 feet. Eastwards it sinks somewhat (Mounts Howitt, Tamboritha, Buffalo, etc., over 5,000 ft.) and narrows to the Hume Range which dies down to 2,000–3,000 ft. towards the Kilmore gap and the Melbourne basin (*q.v.*). These highlands (3,000–4,000 sq.m. above 3,000 ft.), which occupy most of the eastern corner of the State, form a fine and picturesque mountain massif in which ice and rivers, working partly along north-south structural lines (*cf.* the Omeo gap, *c.* 2,800 ft., between the headwaters of the Mitta-Mitta and Tambo rivers) have excavated great wild valleys and given to Victoria a playground (*e.g.*, Mount Buffalo) which rivals the famous Kosciusko area of New South Wales. Westwards from the Kilmore Gap the "range," though similarly broken into spurs (*e.g.*, Mount Alexander 2,430 ft.), is much lower and forms a broad rough upland belt composed largely of ancient metamorphic, with later igneous, rocks (basalt, etc.) rarely rising above 2,000 feet. At the west extremity, just before it sinks to the western plains, lie the north-south Grampian and other ranges (Mt. William, 3,829 ft.). (*b*) The extreme south of the State is occupied by what appear to be fragments of a parallel range, composed largely of later (Mesozoic) rocks. Subsidence in the direction of Bass strait apparently ruptured this system, admitted the sea to Port Phillip, and left the isolated hill-ranges (Otway range rising to 1,900 ft.; Buln Buln [Strzelecki] range with Mt. Fatigue, 2,110 ft.) which occupy the projections on either side of it. Wilson's promontory is a semi-detached granitic mass rising to 2,350 feet. (*c*) Between the two uplands referred to in (*a*) and (*b*) an east-west corridor-like depression stretches nearly the length of the State, from Gippsland to the western plains. In the east it is occupied and has been partly built up, by streams (Latrobe, etc.) which rise in the flanking highlands, and here also the coastal margins south of the Strzelecki range form a parallel and connected lowland. The central portion is the irregularly submerged land-and-water area which opens out as a broad inverted *V* from an apex near Melbourne. To the west the trough runs from about Geelong to the south-west coast (Warrnambool–Portland), and makes junction with the western plains which are the southern extremity of the river Murray basin. Fertile, sheltered and well-watered in the east, in the west these southern Victorian lowlands are paved with wide sheets of Tertiary (Oligocene–Pliocene) basalt—supporting a few small cones and some lakes—which lend to them, as to the northern fringes of Tasmania opposite, an exceptional richness and economic significance. (*d*) Between the Great Dividing Range and the Murray, the north and north-west of the State consists of lowlands undistinguished, except for the flattening mountain spurs along their southern margin, by any outstanding topographic features.

Coastal Features and Drainage.—Of the coastal features the most important are those of the central "water-triangle"—Port Phillip, Corio Bay, Western Port, and other forms of submergence. (*See* MELBOURNE.) Cape Otway, Wilson's promontory and Cape Howe are outstanding points in bold rocky stretches while Portland enjoys shelter from the south-west gales owing to the Cape Nelson projection. The south-east Gippsland coast is noted for its "Ninety Mile Beach" due to longshore sand-drift. Through it a narrow gap at Cunninghame (Lakes Entrance) gives entrance to the long chain of lagoon-like lakes formed by the Latrobe, Macallister, Mitchell, Tambo, and other streams denied free outlet to the sea. Thus is formed an interesting and beautiful district, one of the pleasure-grounds of the State. The south-east streams mentioned, along with the Mitta-Mitta (125 m.), Ovens (110 m.), etc., on the north-east, descend steeply from the eastern highlands and have generally swift, perennial, rain and snow-fed flows capable of supplying an as yet undetermined amount of hydro-electric power. The Murray has *c.* 1,200 m. of its course along the Victorian boundary and, apart from those already mentioned, the Goulburn (280 m.), Campaspe (100 m.) and Loddon (155 m.) are perhaps the most important. Of the remaining south coast streams the Glenelg (280 m.) and the Hopkins-Mt. Emu Creek (135 m. and 170 m.) are the longest.

Climate.—Latitude, relief, and coastal extension (1 m. of coast per 129 sq.m. of land) give to Victoria a relatively mild, warm, and equable climate with a rainfall ranging from moderate to large. Temperatures showing ann. averages of 66°–48° F along the coastal parts become higher and more extreme (76°–51·5°) in the north-west interior, and lower and more extreme (*c.* 56°–32°) in the eastern uplands. Thus, while hot spells are not unknown on the coasts (Melbourne: temps. of 100° recorded on 5–6 consecutive days), they are severer in the north-west (10 days; absolute extremes 117°–21°) while winter temps. below freezing and snow are normal upon the eastern heights. *Rainfall,* which is brought mainly by the west-east procession of southern depressions ("Antarctic lows") and to a less extent by monsoonal depressions from the north ("tropical lows"), is also markedly influenced by land elevation and coastal or interior position. Thus the southern "lows," bringing winter rain, pass mainly along the southern side of the Great Dividing range while the tropical lows are likewise obstructed and visit chiefly the north-east of the State. Similarly while the eastern heights have falls of 50–75 in. and the Otway Range *c.* 40 in., the "Mallee" in the north-west has an average of 12·6 inches. Two areas again—one a lowland strip 25–50 m. wide extending from about Ararat south-east and east to the eastern side of Port Phillip bay and thence north-east to the Kilmore gap, the other a small area around Sale in Gippsland—are in marked rain-shadows and, though flanked by areas of 25–40 in., receive under 20 inches. Apart from such irregularities rainfall in general diminishes from 40–60 in. and over along the south and in the east to 10–12 in. in the north-west of the State.

Water Supply; Mining, and Power.—Except in the north and the north-west, Victoria is relatively free from the water-supply problems which confront most of the Australian States. Nevertheless the rainfall in the drier areas was sufficiently low and unreliable to cause loss in times of drought and extensive boring (1886–1906) revealed mainly either medium or poor (saline) waters or none at all. Later a large area was discovered in the "Mallee" having good sub-artesian supplies at 150–750 ft. which led to settlement along the belt now traversed by the Ouyen–Pinnaroo (South Australia) railway line. Altogether there were (1926) 374 bores in the Mallee, besides others in the Maffra (Gippsland) district. On the other hand the climate was sufficiently hot and dry, and there was enough water available but going to waste, to stimulate water-supply and irrigation schemes, particularly in the north and north-west, on a scale large according to any standard. For this also the surface configuration was adapted—an arc of highland catchment, fairly extensive upper basins of streams which, fed with winter or perennial rains, descended with some speed and volume into broad lower valleys before debouching upon flat alluvial-floored plains. Natural hollows, lagoons and basins also assisted the construction of storage reservoirs while the rainfall and carrying capacity of the land is sufficient to justify large-scale expenditure upon additional water supply. Earlier experience of private or semi-private enterprises (water trusts, etc.) led to the vesting of powers in the State Rivers and Water Supply Commission which now controls all such works excepting those of Mildura, Melbourne, Geelong

and certain municipalities and which in addition acts for Victoria in connection with the River Murray development scheme. Apart from urban and municipal supplies, the schemes have in general two aims, (*a*) the supply of water to country areas for domestic, stock and in one case (Coliban–Castlemaine–Bendigo) for mining, purposes. (*b*) The supply of water for irrigation, the two types being naturally often associated. The irrigated areas (1926/7) covered an area of 406,500 ac., while the rural areas supplied with water for domestic and stock purposes amounted to some 23,200 sq.m. or *c.* 27% of the whole State and lay chiefly in the Mallee and Wimmera districts. In 1927 there was storage accommodation (reservoirs, etc.) for 2,330,500 ac.ft. (1 ac.ft.= 43,560 cu.ft.=272,250 gall. water) existing or under construction in the State, and of this *c.* 2,280,000 ac. ft. (including a share in the Hume Reservoir, *v. inf.*) is under the control of the State Rivers and Water Supply Commission. The water is supplied mainly by gravitation but along the lower (Victorian) Murray by pumping (*e.g.*, Mildura, Millewa, Red Cliffs areas), and in one case (Sugarloaf reservoir, upper Goulburn river) a hydro-electric power scheme is associated (*v. inf.*). Associated, or of a similar nature, are flood-control and drainage works (*e.g.*, West Gippsland; lower Goulburn and Loddon, covering in all *c.* 160,000 ac.). As instances of the scope of these schemes may be mentioned: the Wimmera–Mallee Supply Scheme, capacity *c.* 213,000 ac.ft., supplying *c.* 11,000 sq.m. through *c.* 10,500 m. of channels; in the northern Mallee, schemes designed to supply *c.* 2½ million ac. and including some 720 m. of channels, 100 bore-wells and 260 excavated tanks (1,210,000 cu.yd.); the Goulburn schemes (Sugarloaf, Waranga, etc., reservoirs), 360,000 ac.ft. These supply continually increasing areas. Of the works on the Murray assigned to Victoria under the River Murray Waters Act the Torrumbarry Weir is completed and the great Hume reservoir above Albury (*q.v.*) (2,000,000 ac.ft.; Victorian share, 1,000,000 ac.ft.) and one lock are being completed. Besides these State undertakings the Mildura Trust irrigates (1926/7) upwards of 42,000 acres. By 1927 the Government had expended some £28,000,000 upon works of the above description in Victoria (*v. inf.* Agriculture).

Mining.—This, as elsewhere in Australia, has greatly declined. The principal metal produced is gold (50,000–54,000 oz.; £209,000), chiefly in the Beechworth, Bendigo and Castlemaine areas, but only about 2,000 men are employed. Coal is now of much greater importance. Black coal (Jurassic) exists in southern Gippsland, the chief being at Wonthaggi where the State mine, working within a reserved area of 17 sq.m., has proved reserves of 28 million tons within 5 sq.m. (Output, 1926: 532,000 tons; £585,000). In addition brown coal deposits underlie *c.* 1,200 sq.m. in central Gippsland and have an estimated av. thickness of 50 ft. (at Morwell: 750 ft.). Reserves of 11,000,000,000 tons exist and form a practically inexhaustible source of power, the development and application of which constitutes one of the largest constructive enterprises in the Commonwealth in recent times. Brown coal, machine-mined by open-cut at the two State mines at Morwell and Yallourn respectively, is supplied to a power-station near by having an initial 50,000 kw., and possible 150,000 kw., capacity. From this, and from a smaller station at Newport, power is distributed, through various receiving stations to Melbourne and to over 100 towns in its vicinity, in Gippsland, etc. In addition power generated at Geelong supplies towns as far west as Warrnambool, and the recently-completed hydro-electric power stations on the upper Goulburn (Sugarloaf-Rubicon, etc. area) supply Murray River towns (Albury, Corowa, Echuca) and intervening areas. When completed the system, which is managed by the State Electricity Commission, will supply practically the whole of the south central, north-east, and central northern Victoria and is likely to effect, especially in the metropolitan area, something of a revolution as regards manufacturing industry. In addition at Yallourn is a large briquetting works (*c.* 100,000 tons per annual capacity). The hydro-electric resources which exist mainly in the eastern part of the State are as yet little developed (*v. sup.*). Such as had been surveyed were estimated in 1924 at *c.* 127,000 available h.p.

Vegetation, Timber, Settlement and Land Occupation.—A very large part of Victoria was originally covered with tree-growth of some sort, the bare rock-surfaces of the eastern highlands, the basalt plains of the south-west, and the heath and sand-hill country in parts of the west and north-west being the chief exceptions. But much of this forest, especially in the flatter lands, has been cleared, and the nature and value of the remainder varies. The north-west is characterised by mallee (*cf.* South Australia, Western Australia and *see* AUSTRALIA: *Vegetation*), either as a continuous scrub, or in patches with intervening salt-bush, etc., or in association with other trees (cypress-pine, etc.). In the drier parts of the north and west the forest is of the open (forested steppe) description or consists of river-side belts mainly of red (swamp or river) gum. Of forests proper the chief lie along the uplands, flanks and spurs of the Great Dividing Range, in the Glenelg river basin (*c.* 3,000,000 ac.), on the southern coastal hills, and in the valleys and on the lower and middle slopes of the eastern highlands (*c.* 3,000,000 ac.). The tree types vary from district to district but are prevailingly eucalypts (*cf.* some beech forest on the Otway Range, *cf.* Tasmania) which supply some 20 varieties of useful timber. The finest growths are in the east, notably in Gippsland, though much good timber in the highlands is commercially inaccessible. After long and wasteful exploitation and destruction due to bush-fires, settlement, and mining, the forest resources, under the State Forest Commission, are being carefully husbanded and will provide a valuable and permanent asset. Some 4,330,000 ac. have been reserved, and in addition an extensive scheme of soft-wood plantation (largely *Pinus insignis* for "kraft" paper, butter and fruit packing-cases, etc.) is being prosecuted (*e.g.*, in the south-west) and education in forestry is provided. Sawmilling is an important industry in the Upper Yarra (Warburton), Otway, and Gippsland areas. (*V.* also *inf.* Statistical Survey: *Production, Manufactures, Forestry, Trade, Imports.*)

In spite of relatively large waste areas in the east and north-west, Victoria has a larger proportion of land alienated from the Crown than any other Australian State. At base this is due to the favourable conditions of climate, soil and topography outlined above. It is also due to a fixed and vigorous public policy of land settlement and development, water-supply, irrigation and drainage schemes being perhaps the most striking, but the active subdivision and closer settlement of large estates (*v. inf.* Statistical Survey: *Agriculture*) and the encouragement, through Agricultural colleges (five in number), schools, etc., of improved and intensified production being equally important factors. Within natural limits Victoria has a very wide range of production, and there are few parts of its utilizable area which are physically incapable of yielding a variety of products. The great gold days have long passed and the decline in metal-mining is perhaps permanent. The era of power-development and of manufactures is only beginning, and while this will almost certainly lead to an intensification of Melbourne's predominance and to further concentration of population in the metropolitan area, it will almost as certainly stimulate rural settlement and development and help to overcome some of those difficulties which have faced land-settlement in the past. A comparison of Victoria with Great Britain (each *c.* 88,000 sq.m.) reveals some striking similarities in general primary production, save that the "older" country, with its larger human population, has in general a higher agricultural productivity per unit area and higher densities of cattle population. But the differences are also striking, for nowhere in Great Britain are there the vineyards, irrigated areas, or even the forests which diversify and lend economic range and stability to Victoria and constitute her a well-endowed State.

Agriculture, Fruit, Vines.—The area under cultivation has steadily increased and has more than doubled during the last 20 yrs. (*v. inf.* Statistical Survey: *Agriculture*). This increase, moreover, has not been at the expense of the pastoral industry and of dairying (*v. inf.*) but is due largely to the increasing application, through education, of science to methods of production. Broadly the improvements lie in the direction of fallowing, use of fertilizers, seed breeding and selection, and more skilful rotation of

crops. The value of bare fallow, combined with manuring, has been effectively realised, especially in connection with wheat-growing. Of the total area under crop in 1927 (7,300,000 ac.) over ⅓ (*c.* 2,570,000 ac.) was under fallow and of this 91% was in the three main wheat-growing districts. Similarly the use of manures (*c.* 90 lb. per acre) has steadily increased and is now almost universal (1926: 97% of area under crop), *c.* ⅓ of the total amount used being artificial manures. (*Cf.* 1926/7: imports of 221,000 tons, £529,000, the great bulk being rock phosphate from Nauru, etc.) The five principal arable crops are wheat, oats, barley, potatoes and hay.

Wheat.—For the last five years wheat has occupied an average of 56% of the whole area under crop. The area sown to it increased by nearly one million acres between 1900 and 1927, and has recently again greatly expanded (1927–28: 2,900,000 ac.; 1928–29 [estimated]: 3,826,000 ac.). The yield varies markedly from season to season with the rainfall and also from locality to locality. Thus averages of 18–24 bu. per ac. in the Wimmera (up to 40 bu. and over in favoured parts of the State) are matched by averages of 7–13 bu. in the Mallee, but the average for the State as a whole has steadily risen (aver. 1916–26: 14·13 bu. *cf.* aver. for Australia: 12·41 bu.), though in the recent severe drought it fell to 7·51 bu. (1927–28). Wheat will grow almost anywhere in Victoria where terrain favours, but 94% of the wheat-lands lie in the Wimmera, Mallee and Northern divisions within a triangle bounded on the west by a line from about Mildura to Horsham, on the north by the Murray, and on the south by a line from Horsham to about Corowa. This forms part of the main Australian wheat-belt and from it extensions run westwards towards the South Australian border along strips marked by the lines of railway. The three divisions mentioned contain between them nearly 83% of the cultivated land in the State, the Mallee having 47%, the Wimmera 31% and the Northern 29% of their respective areas under cultivation. By far the greater part of this is utilized for producing wheat. The provision of labour-saving machinery, of railways, and of an assured water-supply have helped to bring into being large-scale commercial production. In 1891–92 the Mallee, generally considered a desert, produced only 5% of the State's wheat; during the last five years it has produced, on an average, 31%, and in 1926–27 nearly 2¾ million acres were under cultivation in this area. The average wheat-farm is 200–250 ac. The total production of wheat, in spite of drought (1927–28: 21,800,000 bu.) is now of the order of 40–50 million bu. of high-grade grain, of which some 12,000,000 bu. are required for seed and for home consumption. The railways, driven in long parallel lines across the level lands, penetrate the wheat areas at spaced intervals and concentrate the grain upon Melbourne, whence it forms a staple export either as grain or as flour (*cf.* 1926–27: 44 flour mills; *c.* 1,100 hands, handling 17 million bushels wheat yielding 360,000 tons flour valued at £5,790,000).

Other Crops.—Oats, grown to a large extent in the wheat areas but also more towards the north-east, and hay, are important subsidiary crops. The place of root crops, under the less intensive farming methods employed, is largely taken by "hay" which includes wheat, oats, lucerne, etc. Thus 150,000–200,000 ac. sown to wheat and *c.* 960,000 ac. oats (1926–27) were cut as hay, and of the total hay crop (1927) of *c.* 1,400,000 tons, 1¼ million tons were oaten, 128,000 tons wheaten and 34,600 tons lucerne. *Potatoes*, of which the production is reviving, are grown mainly on the rich volcanic soils of the Central Division (*c.* 10% of total crop), north Central (*c.* 17%), Western (*c.* 25%), and Gippsland. In these areas the rainfall also is good (25–35 in.) and there is ready access to Melbourne, the main market. Of other arable crops *maize*, grown mainly (91%) in Gippsland where relatively high temps. and summer rainfall are available (1927: 20,000 ac., 685,000 bu.); *onions* (1926–27: 8,500 ac.; 44,000 tons) in the southern valley from about Warrnambool to Melbourne and also south-east of Melbourne (Mornington and Buln Buln); *hops*, are also worthy of mention. At Maffra, near Sale in Central Gippsland, a rising beet-sugar industry is being encouraged by a Government mill and irrigation works (Macallister River) (1926–27: 2,000 ac.; 10,000 tons; 1,200 tons sugar) and steps now being taken by the Commonwealth Government may stimulate tobacco culture (*c.* 1,150 ac.; 8,000 cwt. dry leaf, grown mainly in the north-east). In the neighbourhood of Melbourne, and in the orchard areas also, large quantities of market-garden produce is grown on rich open lands, or by irrigation or under glass (Bacchus Marsh; Werribee; Hallam, etc.) (1926–27: total area market gardens: 17,800 ac.). *Fruit-growing* is widely distributed but commercial orchards exist chiefly in (a) the Melbourne basin, mainly to the south-east, east and north; (b) the irrigated Murray lands (*v. inf.*). Apples, pears and northern fruits, including small (berry) fruits, are largely grown in the south, the sub-tropical varieties predominating in the northern areas (*v. inf.* Statistical Survey: *Agriculture*).

Irrigated Areas (Murray River and other) (*v. sup.*: Water-Supply). The area cultivated under irrigation has steadily increased, the 406,500 ac. of 1926–27 representing an increase of over 70,000 ac. upon the average of the previous five years. An increasing proportion of the space is being devoted to the intensive growing of fodder-crops (several crops per season) and to dairying and stock-fattening in association therewith (1926–27: pastures, 33%; lucerne, 29%, sorghum and other fodders, 7% of total area = *c.* 281,000 ac. in all under fodder crops). Some wheat (10% = 40,600 ac.) is also grown, the high yields (40 bu. or more per ac.) compensating for relatively expensive methods. Better known, perhaps, is the fruit production of the Murray river irrigation areas, especially those sub-tropical varieties (apricots, peaches, oranges, etc.; grapes, raisins, currants, etc.) which are favoured by the presence of good stiff (semi-retentive) soils, ground-moisture, together with dryness, warmth and sunshine at the right periods. The industry flourishes particularly in the Mildura and Shepparton areas (1926–27: 17% of total irrigated area = 69,000 ac.). The relative stability of production conditions, the suitability for "small" settlers, increasing co-operation in production and marketing have steadily attracted settlers (*e.g.*, 1905–1927: increase of 30,000 in irrigation areas compared with decreases in rural population of Victoria as a whole. Mildura [42,200 ac.]: Pop., 1911: 6,120; 1927: 15,100). At the same time, production far exceeds home consumption (*e.g.*, 1927: raisin production: *c.* 658,000 cwt.; home consumption, *c.* 88,000 cwt.; currants: 135,500 cwt.; *c.* 30,000 cwt. Surplus: raisins: *c.* 570,000 cwt.; currants, *c.* 105,000 cwt.) and markets abroad are therefore essential.

Pastoral Industries; Dairying, etc.—Partly in spite of, and partly because of the general progress in agriculture, the pastoral and dairying industries are also expanding, sheep, dairy cows and pigs in particular having increased in numbers in recent years. Victoria now takes rank with New South Wales as one of the leading dairying States of the Commonwealth. The industry is carried on in the irrigation areas (*v. sup.*) but mainly in the southern plains, from east to west of the State, where low and well-watered lands, a humid climate (upwards of 30 in. rainfall) and market and export facilities exist (Melbourne, Portland, Warrnambool, etc.). Cheese and butter factories are numerous and places such as Colac and Terang in the south-west, Morwell and Bairnsdale in Gippsland; Kerang and Wangaratta in the north are dairying centres. Great attention is paid to scientific education and to improved methods of production, marketing, etc. Associated is the pig-rearing industry (bacon-curing, etc.) and also bee and, increasingly, poultry keeping. *Cattle* (for slaughter) are grazed over wide areas and fattened in the southern agricultural districts, but the industry has a mainly domestic value (*e.g.*, of the 500,000 head slaughtered in 1926, *c.* 484,000 were for home consumption). *Sheep*-rearing has a far wider commercial significance, Victoria being one of the leading wool and mutton producers in Australia. The total number carried has risen steadily to *c.* 15 million head in 1927, and the fact that *c.* 80% of the total is comprised in flocks of 500–5,000 head is evidence of the more intensive production methods referred to (*cf.* flocks of 20,000 and upwards: 1·53%). From the rougher and wetter lands sheep have been, for physical or economic reasons, gradually excluded and 65% of the total number are now found in the Western, Wimmera and Northern divisions (Western: 32·66%, 25,900,000 lb. wool [1926–27]; Wimmera: 16·84%, 17,100,000

lb.; Northern: 15·62%, 17,240,000 lb.). The sheep-lands, in fact, stretch in a broad band from south-west to north-east across the State and form part of the great sheep-belt of eastern Australia which extends into the Riverina (New South Wales, *q.v.*) and beyond. The fleeces are of good average weight (7–8 lb.) and the wool, particularly that from the western plains, is clean, long and well-coloured and is in great demand. Of the total production (1926–27: 121,300,000 lb.) about ¼ (1926–27: 31,000,000 lb.) is taken by the Victorian textile etc. mills and the remainder is exported (1925–26: 60% crossbred etc.; 18·5 merino). Woollen and knitting mills are situated in Melbourne, Geelong, Castlemaine, Ballarat, Warrnambool and other centres and the industry is steadily expanding. Mutton and lamb export is conducted on a large scale. Of 4,530,000 head slaughtered in 1926, 30% were exported frozen from 13 freezing works, total exports amounting in 1927 to 47,300,000 lb. (£1,195,500). (*V.* also *inf.* Statistical Survey: *Production, Pastoral Industries, Manufacturing Industries, Trade.*)

Manufacturing Industries; Communications; Trade; etc.—Manufacturing industries in Victoria fall into three main classes (*a*) those closely connected with primary production: sawmilling, cheese and butter making, bacon-curing, meat-freezing, fruit-canning, etc. (*b*) those of a rather more developed nature but still dependent upon primary production: woollen and hosiery mills; furniture-making; power production, etc. (*c*) those of more purely secondary character often dependent, in whole or in part, upon imported raw or semi-manufactured materials (manufacture of motor-vehicles, agricultural machinery, railway rolling-stock, etc.). Many of these have been referred to above (*v.* also Melbourne and *inf.*, Statistical Survey: *Manufacturing Industries*). Since 1917–18 the number of factories and of workers have each increased by 37%, the value of output by 90%, and the horse-power employed by 178%. Steam is still the chief motive power, but the number of factories using electricity has increased remarkably (1926–27: *Steam,* 678 factories using 268,000 h.p.; *Electric,* 5,141 factories using 123,360 h.p.), and the possibilities in connection with electricity have been indicated above.

Communications.—These, as a natural consequence of the relatively small area, high productivity, and also of the energy of the people, are on the whole better developed in Victoria than in any other Australian State (*e.g.,* Victoria had, in 1926, 53·34 m. of railway per 1,000 sq.m. of territory; *cf.* Tasmania: 40·9; New South Wales, 19·6; Australia: 9·56). Apart from mountainous and barren areas, there are few parts which are not readily accessible. Areas distant more than 10 m. from a railway hardly exist except in the east and in some few parts in the west. Roads suitable for motor traffic are wide-spread. Railways (*v. inf.*, Statistical Survey) are virtually all State-owned, of 5′ 3″ gauge, and fall into the following main classes (*a*) through routes connecting Melbourne with Sydney (viâ Albury, where a break to the 4′ 8½″ "standard" gauge of New South Wales occurs), and with Adelaide (viâ Ballarat, Serviceton and Wolseley: *see* South Australia), (*b*) east-west intra-State lines serving the "Great (Southern) Valley" and the south coast from Warrnambool to the Snowy River (Gippsland), (*c*) an impressive system of lines running roughly parallel north-east, north, but mainly north-west, draining the northern plains, the Murray valley, and the wheatlands of the north-west. These lines give a striking impression of purposeful striving and reaching forward, and this indeed they do to the extent of tapping the south-western (trans-Murray) Riverina (*q.v.*) in New South Wales, (*d*) the denser metropolitan net around Melbourne and Port Phillip bay, now electrified in its suburban units. A fifth type is visible but is not strongly developed: viz., north-south lines draining the hinterlands to their nearest convenient ports (*e.g.,* Portland, Warrnambool). Melbourne is connected with Tasmania by submarine cable.

Trade.—Some details regarding trade have already been given and a survey is afforded below. (*See* Statistical Survey: *Trade.*) Victoria's trade amounts in general to 27–30% of that of the Commonwealth. Of her exports wool, wheat, flour and butter amounted, during the last five years, to 73% of the total—or adding skins, meat, and fruit: 89%—wool alone accounting for 42%. Nearly 40% of Victorian exports went (1927) to, and 43% of her imports came from, the British Isles. Trade with the United States amounted to £15,000,000 (16·6% of total); that with India and Ceylon amounted to *c.* £3,500,000; with New Zealand to £2,320,000.

Shipping and Ports.—*v. inf.*, Statistical Survey. (Note that vessels there mentioned do not include River Murray steamers.)

Population.—Statistics regarding the population of the State are given below (*see* Statistical Survey). The great preponderance of population in the metropolitan area is worthy of note. Some indications of the reasons will be found above (*see* also Melbourne) and the growth of manufacturing industries in this area has been referred to (*cf.* 5,160 factories out of the State's total of 7,690). Outside of Melbourne the most densely populated parts are (1) the surroundings of Melbourne comprised within the rim of the Melbourne basin and around the shores of Port Phillip, the latter mainly seaside and residential settlements on the east—Mordialloc (1926: 7,760), Mornington, Sorrento—and, on the west, industrial areas as well as Geelong (pop. 41,000; *q.v.*); (2) Ballarat (*q.v.*) and Bendigo (*q.v.*) and the districts for which they serve as centres; (3) the southern coastal portions, particularly from Geelong to Warrnambool and southern and central Gippsland. The remainder of the State is more sparsely settled, but the main belts and concentrations extend north-eastwards along the main overland railway-line: Seymour, Benalla, Wangaratta (3,900), Albury (*q.v.*)—formerly mining, now mainly agricultural and pastoral centres—and along the Murray irrigation settlements, *e.g.,* Mildura (6,000). The west is much more evenly and also more sparsely settled, densities continually decreasing towards the west except that, as elsewhere and in general, the railway lines mark zones of heavier population and themselves usually follow belts of better lands (*cf.* the striking instance of the Ouyen-Pinnaroo line which follows the belt of sub-surface waters). A fairly clear indication of the character of the rural settlements in Victoria will be conveyed by the general economic description given above. By far the greater number are agricultural, dairying or irrigation centres, often a combination of several types (Hamilton, 5,300; Stawell, 4,700; Horsham, 4,200). It is noteworthy that Victoria, with *c.* 19·5 persons per sq.m., is by far the most densely populated State of the Commonwealth (*cf.* Tasmania, 8·2; New South Wales, 7·6; Commonwealth, 2·1).

Statistical Survey.—*Area and Land Occupation: Area:* 87,844 sq.m. (56,245,760 ac.) = 2·96% Commonwealth; wholly within the temperate zone. Coast-line: 680 m.-1 m. per 129 sq. miles. *Land Occupation* (1926–27); alienated: 34,446,200 ac.; Crown lands: 21,800,000 ac. (forest, etc., reserves: 4,635,000 ac.; Mallee and other reserves: 821,000 ac.; leases and licences: 6,200,000 ac.; unoccupied: 5,751,000 ac.). *Area under cultivation* (1926–27): 7,304,200 ac. *Area under pasture:* (1925–26): 29,830,000 ac.

Population (estimated Dec. 31, 1927): 1,741,400 (males: 867,400; females: 874,000) = *c.* 28% of Commonwealth total and *c.* 19·5 per sq. mile. Birth rate (1926): 20·84; death rate: 9·63 per 1,000. Metropolitan (1927), Melbourne and suburbs (165,666 ac.): 975,160 = *c.* 55·3% of total. Net increase (ten years: 1911–21): 16·4%; absolute increase (1926): 27,800. Rates of increase (1926): State = 1·65%; metropolitan: 3·54%; remainder of State, −·58%.

Occupations (census, 1921: total pop., 1,531,280): *Breadwinners:* 669,453 of whom: *Industrial,* 234,245; *Primary Producers,* 147,438 (agricultural, 103,116; pastoral, 22,679; mining and quarrying, 8,679; forestry, 8,153; water conservation and supply, 2,808). *Commercial:* 108,011; *Professional:* 60,585; *Domestic:* 58, 225; *Transport:* 53,332.

Production (1926–27): Total £98,342,400. *Manufactures* (added value): £51,005,400. *Total primary* 47,337,000. *Dairying and Pastoral:* £22,280,400 (*Dairy:* butter, £6,233,400; milk, etc. [liquid] £2,481,000; milk [condensed] etc., £1,498,000. *Pastoral:* wool, £7,876,700; sheep [mutton], £2,585,700; cattle, £2,331,000; pigs, £1,343,700). *Agricultural, etc.:* Total £15,745,000 (Wheat, £9,546,800; other cereals, £1,159,500; hay and fodder, £5,204,100; vine products—grapes, raisins, currants—£1,551,600; wine, £254,-

200; fruit, £971,000; vegetables etc., £887,500). *Poultry:* £4,819,500. *Forests* (timber, fire-wood, tan bark): £1,888,800. *Mining:* £1,880,200. *Production: value per caput:* Total £57. 9. 0. *Manufactures:* £29. 15. 11. *Total primary:* £27. 13. 1 (dairy and pastoral £13. 0. 4; cultivation £9. 4. 0; forests £1. 2. 1). *Mining:* £1. 1. 11.

Manufacturing Industries: (1926–27) Factories: 7,690, of which 5,158 in metropolis (10 years, 1917–27: 37% increase); workers, 161,640 (=37% increase); value added in process, £54,188,570; total (net) value of output, £127,398,000. *Food and Drink:* Factories: 732 (including butter, 182; jam, etc., 58; bacon curing, 21; meat freezing, etc., 13); workers, 18,880; output, £36,072,000. *Clothing and Textiles:* 2,087 (including woollen mills, 27; hosiery, 176; boots, etc., 204); 55,100; £27,592,000. *Metal, Machinery, etc.:* 1,023 (including engineering 315; iron and foundries 117; agricultural implements 73; railway workshops 21); 28,560; £17,693,000. *Printing, etc.:* 582; 11,720; £7,091,000. *Raw Materials:* 243; 4,112; £6,452,000. *Work in Wood:* 678 (including sawmills, 207; joinery 336); 9,134; £5,379,000. *Heat, Light, Power:* 129 (including electric light, 86); 2,984; £5,066,000. *Vehicles, etc.:* 949; 8,236; £3,590,000.

Mining and Quarrying (1926): Total: £1,782,200. Stone: £700,200; coal, black (591,000 tons) £657,800; brown (958,000 tons) £188,900; gold: £208,500.

Agriculture (1926–27): *Area cultivated:* 7,304,200 ac. (*cf.* 1895–1905: *c.* 3·55 million ac. [aver.]; 1905–15: 5·03 million ac.; 1920–25: *c.* 6·9 million ac.). *Size of Holdings:* 10,000 ac. and over: 1925, 104 holdings aggregating 1,577,000 ac. (*cf.* 1906: 195 aggregating 4,134,000 ac.); 5,000–10,000 ac.: 273 holdings aggregating 1,869,000 ac. (also declining); all holdings smaller than above increasing in number. *Production: Wheat:* 2,915,000 ac. (*c.* 56% of area cropped); 46,886,000 bu. (aver. 12–17 bu. per ac.); £9,547,000. *Hay:* 1,081,000 ac.; 1,388,000 tons; £4,720,000. *Oats:* 303,400 ac.; 4,884,000 bu.; £653,000. *Potatoes:* 66,200 ac.; 163,000 tons; £672,000. Ann. value of five principal crops (*i.e.*, including barley), 1923–27: £12·5–£17·6 mill. *Vines:* 2,832 growers; 41,160 ac.; 3,587,000 bu. grapes; (wine: 2,346,300 gal.; raisins: 657,700 cwt., £1,294,300; currants: 135,500 cwt., £182,500). *Gardens and Orchards:* 101,000 ac. (mainly apples, pears, peaches, oranges, apricots, plums), value, including table grapes, £1,055,300. Market gardens, £888,000.

Irrigation (1926–27): 406,530 ac. (=increase of 70,060 ac. over average for previous five years).

Pastoral and Dairying (1927): *Live stock:* horses: 448,000; dairy-cows: 673,000; other cattle: 763,000; sheep: 14,920,000; pigs: 284,300. *Density* (estimated): 1911: 302; 1927: 319, live stock per sq. mile. *Production: Stock slaughtered* (1926): sheep, 4,528,000 (£2,586,000); cattle, 499,500 (£2,331,000); pigs, 410,000 (bacon, *c.* 21 million lb.) (£1,344,000). *Dairying* (1927): Owners, 56,935; cows, 673,000; butter, 82 million lb. (£6,233,400); cheese, *c.* 6 million lb. (£270,600); milk, etc., (£3,980,000). *Wool* (1926–27): clip 98·2 million lb.; wool on skins, *c.* 23 million lb.; total wool, *c.* 121,300,000 lb., £7,877,000 (1923–24—1926–27: £7,083,000–£11,444,000). Fleece (aver.): 6·5–7 lb. *Honey:* 54,000 hives; 2,370,000 lb. honey; 33,240 lb. wax; £47,300.

Forestry and Fisheries: Fisheries (1926–27): 845 boats; 1,260 men; catch, *c.* £167,500. *Forests:* Wooded area: *c.* 8 million ac.; dedicated forests: *c.* 4·33 million ac.; sawmills (1926–27): 207; workers, 2,860; Victorian timber cut: 115·8 million super ft., £914,300 (*v. sup.*: Production).

Trade, Commerce, Communications: Trade (1926–27: overseas only): *Total:* £90,302,600=29·2% of Commonwealth total. Excess of imports over exports: £20,819,000. *Exports:* £34,741,700=£20. 5. 11 per caput; 24% of Commonwealth total. *Wool:* £14,306,000 (177·5 million lb.); *hides and skins:* £2,106,000; *frozen meats:* £1,323,000; *wheat:* £6,976,700 (24·75 million bu.); *flour:* £2,123,000 (167,000 tons); *butter:* £2,612,000 (34·4 million lb.); *milk*, etc.: £1,067,000; *fruits* (dried and preserved): £1,400,000. *Imports:* £55,561,000=£32. 9. 2 per caput; 33·7% of Commonwealth total. *Textiles, clothing, etc.:* £17,073,000; *metals, machinery, motors, etc.:* £15,700,000; *oils:* £3,204,500; *foodstuffs:* £3,187,000; *stationery, paper, etc.:* £2,707,000; *rubber and leather manufactures:* £2,411,000; *timber and worked wood:* £1,947,000; *drugs and chemicals:* £1,900,000.

Shipping (1927: overseas and interstate): Vessels cleared: overseas: 2,666, 7,181,000 tons; interstate: *c.* 2,000 vessels, 4,322,000 tons; of which total 2,352 vessels (6,067,000 tons) British, 1,636 vessels (2,246,000 tons) Australian.

Ports (1926–27): *Melbourne:* 4,000 vessels (7,325,000 tons), of which overseas: 765 (3,296,000 tons); interstate: 1,770 (3,625,000 tons); local (within State): 1,466 (403,300 tons). Cargo: discharged, 3,754,000 tons (1,853,000 tons overseas); shipped, 1,501,300 tons (826,700 tons overseas). *Geelong:* 750 vessels (770,900 tons). Cargo discharged, 279,500 tons; shipped, 321,000 tons. *Portland:* 108 vessels (152,000 tons); discharged, 9,800 tons; shipped, 44,950 tons. *Warrnambool:* 150 vessels (49,000 tons); discharged, 23,700 tons; shipped 4,200 tons.

Railways (1927): State-owned lines: 4,692 m. open, 68 m. under construction; 103 m. authorized. Net profit on working: £3,240,000. Loss (after meeting interest charges): £47,540.

Finance: Public revenue (1926–27): £27,128,700; public expenditure: £27,744,903; public debt: £149,546,966; (average rate of interest payable: 4·91%; debt per caput [1925–26], £82. 15. 7). Total taxation (1925–26): £24,649,770 (£14. 12. 9 per caput). Revenue per caput (1925–26), £15. 0. 1; expenditure per caput: £15. 3. 7. Accumulated deficiency: £977,500. Bank deposits (total, 1927): £157,989,366. Joint Stock Banks: Assets: £99,962,000; liabilities: £93,539,000; deposits: £91,924,000. State Savings Bank (1927): depositors 1,167,630; balances: £58,304,000. Savings Banks (State, Commonwealth, School) (1926): deposits: £63,254,000 (£37. 6. 7 per caput of population).

Social: Schools (1926): Total 3,020; scholars: 326,900. State, 2,525; teachers, 7,000; scholars, 255,100. Cost per scholar, £13. 5. 6. Private: 495; 2,210; 71,770. *University of Melbourne:* students: 2,720; receipts: £198,900; expenditure: £147,100.

State Expenditure (1925–26) upon: Education: £3,025,700 (£1. 15. 11 per caput of population); charitable institutions: £1,096,300; pensions, etc. £656,800. (O. H. T. R.)

HISTORY

The first discoverer of Victoria, formerly a part of New South Wales (*q.v.*) was Captain Cook in command of H.M.S. "Endeavour," who sighted Cape Everard on April 19, 1770, a few days prior to his arrival at Botany bay. The first persons to land in Victoria were the supercargo and a portion of the crew of the merchant ship "Sydney Cove" which was wrecked at the Furneaux islands in Bass strait on Feb. 9, 1797. In 1802, Port Philip was discovered by Lieut. Murray, and in 1804 Lieut.-Col. Collins attempted to form a settlement there. After three months he was compelled to abandon the scheme, and to remove his party to Van Diemen's Land. In 1826 a convict establishment was attempted by the Government of New South Wales at Settlement Point but it was soon abandoned. In 1834 Edward and Francis Henty, who had taken part in the original expedition to Swan river, Western Australia, and afterwards migrated to Van Diemen's Land, crossed Bass strait, established a shore whaling station at Portland bay, and formed sheep and cattle stations on the river Wannon and Wando rivulet, near the site of the present towns of Merino, Casterton and Coleraine. In 1835 a number of flock owners in Van Diemen's Land purchased through Batman from the aborigines a tract of 700,000 acres on the shores of Port Philip. The sale was repudiated by the British Government. Batman, however, remained at Port Philip, and commenced farming within the boundaries of the present city of Melbourne. He was followed by John Pascoe Fawkner and other settlers from Van Diemen's Land, who occupied the fertile plains of the new territory. In 1836 Captain Lonsdale was sent to Melbourne by the Government of New South Wales to act as resident magistrate in Port Philip. The first census taken in 1838 showed that the population was 3,511, of whom 3,080 were males and 431 females. In 1841, owing to the constant immigration from Great Britain, the population had increased to 11,738. Melbourne was incorporated as a town in 1842, and was raised to the dignity of a city in 1847. The third census (which was taken in 1846) showed a population of 32,870.

The elective element was introduced into the legislative council of New South Wales in 1842, in the proportion of 24 members to 12 nominated by the Crown, and the district of Port Phillip, including Melbourne, returned six members. But the colonists were not satisfied with government from and by Sydney; an agitation in favour of separation commenced, and in 1851 Victoria was formed into a separate colony with an executive council appointed by the Crown, and a legislative council, partly elective and partly nominated, on the same lines as that of New South Wales. The population at that date was 77,435. Gold was discovered a few weeks after the colony had entered upon its separate existence, and a large number of persons were attracted to the mines, first from the neighbouring colonies and subsequently from Europe and America.

Local self-government was introduced in 1853, and the legislature found time to discuss a new constitution, which not only eliminated the nominee element from the legislature, but made the executive Government responsible to the people. The administration of the goldfields was not popular, and the miners were dissatisfied at the amount charged for permission to mine for gold, and at there being no representation for the goldfields in the local legislature. The discontent culminated at Ballarat in Dec. 1854, in riots in which there was a considerable loss of life both amongst the miners and the troops. Eventually, an export duty on gold was substituted for the licence fee, but every miner had to take out a right which enabled him to occupy a limited area of land for mining and also for residence. The new constitution was proclaimed in 1855. The crown lands were occupied by graziers, termed locally "squatters," who held them under a licence renewable annually at a low rental. These licences were very valuable, and the goodwill of a grazing farm or "run" commanded a high price. Persons who desired to acquire freehold for the purpose of tillage could only do so by purchasing the land at auction, and the local squatters, unwilling to be deprived of any portion of a valuable property, were generally willing to pay a price per acre with which no person of small means desirous of embarking upon agricultural pursuits could compete. The result was that although the population had increased in 1861 to 540,322 the area of land under crop had not grown proportionately, and Victoria was dependent upon neighbouring colonies and even more distant countries for a considerable portion of its food. A series of Land Acts was passed, the first in 1860, with the view of encouraging a class of small freeholders. The principle underlying all these laws was that residence by landowners on their farms, and their cultivation, were more important to the State than the sum realized by the sale of the land. The policy was only partially successful, and by a number of ingenious evasions a large proportion of the best land in the colony passed into the possession of the original squatters. But a sufficient proportion was purchased by small farmers to convert Victoria into a great agricultural country, and to enable it to export large quantities of farm and dairy produce.

The greater portion of the revenue was raised by the taxation through the customs of a small number of products, such as spirits, tobacco, wine, tea, coffee, etc. But an agitation arose in favour of such an adjustment of the import duties as would protect the manufactures which at that time were being commenced. A determined opposition to this policy was made by a large minority in the Assembly, and by a large majority in the Council (the "Upper House") but by degrees the democratic party triumphed. Notwithstanding these struggles the population of the colony steadily increased, and the legislature found time to pass some measures which affected the social life and the commercial position of the colonies. State aid to religion was abolished, and divorce was made comparatively easy. A system of free, compulsory and secular primary education was introduced. The import duties were increased and the transfer of land was simplified. In 1880 a fortnightly mail service via Suez between England and Melbourne was introduced, and in the following year the census showed a population of 862,346. During the same year the lengthy dispute between the two houses of parliament was brought to an end by the passage of an Act which reduced the qualifications for members and the election of the legislative council, shortened the tenure of their seats, increased the number of provinces to 14 and the number of members to 42. In 1883, a Coalition Government, in which the Liberal or Protectionist and the Conservative or Free-trade Party were represented, took office, and with some changes remained in power for seven years. During this political truce several important changes were made in the constitution. An Act for giving greater facilities for divorce was passed, and with some difficulty obtained the Royal assent. The Victorian railways were handed over to the control of three commissioners, who to a considerable extent were made independent of the Government, and the civil service was placed under the supervision of an independent board. In 1890 all the Australian colonies, including New Zealand, sent representatives to a conference at Melbourne, at which resolutions were passed in favour of the establishment of a National Australian Convention, to consider a scheme for the Federal constitution. This Convention met in Sydney in 1891 and took the first step towards federation (*see* AUSTRALIA).

In 1891 the Coalition Government resigned and a Liberal administration was formed. An Act passed in that year placed the railways again under the control of the Government. Measures of a democratic and collectivist tendency thereafter obtained the assent of the legislature. The franchise of property-holders not resident in an electorate was abolished and the principle of "one man one vote" was established. Acts were passed sanctioning old age pensions; prohibiting shops, except those selling perishable goods, from keeping open more than eight hours; compelling the proprietors to give their assistants one half-holiday every six days; preventing persons from working more than 48 hours a week; and appointing for each trade a tribunal composed of an equal number of employers and employed to fix a minimum wage.

Victoria enjoyed a large measure of prosperity during the later '80s and earlier '90s, and its financial prosperity enabled the Government to expend large sums in extending railway communication to almost every locality and to commence a system of irrigation. The soil of Victoria is on the whole more fertile than in any other colony on the mainland of Australia. The rainfall is more equable than in any portion of Australia, but the northern and north-western districts are subject to droughts, and costly irrigation schemes have not proved as successful as was expected. In 1892 the prosperity of the colony was checked by a great strike which for some months affected production, but speculation in land continued for some time longer, especially in Melbourne, which at that time contained nearly half the population (500,000 out of a total of 1,140,105). In 1893 there was a collapse. The value of land declined enormously, hundreds of persons believed to be wealthy were ruined, and there was a financial panic, which caused the suspension of all the banks, with the exception of the Australasia, the Union of Australia, and the New South Wales. Most of them resumed payment; but three went into liquidation. It was some years before the normal condition of prosperity was restored, but the great resources of the colony and the energy of its people discovered new markets, and new products for them, and enabled them materially to increase the export trade. In 1908 female suffrage was instituted. Members of the legislative assembly need no property qualification and clergymen of any denominations are not allowed to be members of the legislative council or legislative assembly. Victoria was federated with all the other Australian States into the Commonwealth of Australia on Jan. 1, 1901. (*See* also AUSTRALIA.)

VICTORIA, a city and port of Brazil, capital of the state of Espirito Santo, on the west side of an island at the head of the Bay of Espirito Santo. Pop. (1920), 21,866. The principal streets follow the water-line, rising in terraces from the shore, and are crossed by narrow, steep, roughly paved streets. The buildings are old and of the colonial type. The entrance to the bay is rather tortuous and difficult, but is sufficiently deep for the largest vessels. The harbour is not large, but is safe and deep, being completely shut in by hills. Large quays, piers, warehouses, etc., facilitate the handling of cargoes. Victoria is a port of call for coasting steamers and a shipping port in the coffee trade. The

other exports are sugar, rice and mandioca (manioc) to home ports. A railway starting at Victoria connects with Río de Janeiro, 270 m. to the southwest. Another line runs north and west into the important mineral region of Minas Geraes, for which it provides an outlet.

Victoria was founded in 1535 by Vasco Fernando Coutinho, on the south side and nearer the entrance to the bay, and received the name of Espirito Santo. The old site is still occupied, and is known as Villa Velha (Old Town).

VICTORIA, capital of British Columbia, Canada, and principal city of Vancouver island, in the south-east corner of which it is finely situated. It is on the Canadian National railway, and is the terminus of a line from Esquimalt and Nanaimo and the coast beyond. There is also a line across the Saanich peninsula. Victoria, which is a fine city with many gardens, the oldest in the province, has a splendid parliament building, the large Dominion astrophysical observatory, and a university. The city is a favourite tourist resort. The population was 38,727 in 1921 (over 60,000 including suburbs), and includes a number of Chinese. The port, which is the fourth in Canada, is fine and well-equipped. Steamers run daily to points on the British Columbian coast, and to Australia and the East, and it is the headquarters of the Royal Canadian navy. The city is an industrial centre, the principal products being canned fish, biscuits, timber, soap, machinery, furniture, boots and clothing, bricks and cement. There is a large trade in coal, timber, canned salmon, etc. Until the redistribution of the fleet in 1905, the headquarters of the British Pacific squadron were at Esquimalt (pop. in 1921, 6,484), a fine harbour 3 m. W. of Victoria. It is provided with graving and dry docks, and another dry dock was in course of construction in 1924. It has a naval college, and is defended by fortifications of a modern type.

VICTORIA, a city of Texas, U.S.A., 120 m. S.W. of Houston, on the Guadalupe river, 35 m. from Matagorda bay (Gulf of Mexico); the county seat of Victoria county. It is on Federal highway 96, and is served by the Missouri Pacific and the Southern Pacific railways. The population was 5,957 in 1920 (70% native white and 19% negroes) and was estimated locally at 8,750 in 1928. It is a "city of roses," and the trade centre of a rich agricultural region, in which cotton is still the leading crop but diversified farming is rapidly increasing. The project of an intracoastal canal from New Orleans to Corpus Christi (finally approved by Congress in 1927) had its inception in Victoria in 1906, and the Guadalupe river up to this point is included in the canal system. Victoria was settled by the Spanish about 1824 and was incorporated as a city of Texas in 1837.

VICTORIA, LAKE, the largest lake in Africa and chief reservoir of the Nile, lying between 0° 20′ N. to 3° S. and 31° 40′ to 34° 52′ E. Among the fresh-water lakes of the world it is exceeded in size by Lake Superior only and has an area of over 26,000 sq.m. In shape it is an irregular quadrilateral, but its shores, save on the west, are deeply indented. Its greatest length from north to south is 250 m., its greatest breadth 200 m. Its coast-line exceeds 2,000 m. It fills a shallow depression in the central part of the great plateau which stretches between the western and eastern rift-valleys (*see* AFRICA), and has an elevation of about 3,720 ft. above the sea. Its greatest ascertained depth is a little over 270 ft., and it is remarkable for the severe and sudden storms which render navigation dangerous. It contains many archipelagos, the majority being near the coast-line. The lake is full of reefs, many just below the surface of the clear water. It is abundantly stocked with fish. The land surrounding the lake consists of gneiss, quartz and schistose rocks, covered with marl and red clay and in the valleys with loam.

Shores and Islands.—The shores of the lake present varied aspects. The western coast, which contains no large indentations, is, in the south, backed by precipices 300 ft. high, behind which rise downs to thrice the height of the cliffs. Going north, the hills give way to papyrus and ambach swamps, which mark the delta of the Kagera. Beyond the delta the hills reappear, and increase in height, till at the north-west corner they rise some 500 ft. above the water. This western shore is marked by north to south faults which run parallel to the lake at a short distance inland. The northern coast is very deeply indented and is marked by rocky headlands jutting into the waters. This high land is narrow, and streams which rise on its northern face drain north away from the lake. On a promontory about 30 m. east of the Katonga is Entebbe, the port and administrative centre of the Uganda Protectorate. The chief indentations on the north side are Murchison bay and Napoleon gulf. Napoleon gulf itself is deeply indented, one bay, that of Jinja, being the outlet of the Nile, the water here forcing its way over the Ripon falls through the rock-bound shore of the lake. The north-east corner of the lake is flat and bare. A narrow channel leads into Kawirondo gulf, which, with an average width of 6 m., extends for 45 m. to Kisumu, the terminus of the railway from the east coast of Africa. Hills dominate the south shore of the gulf and behind them is the Kasagunga range. Proceeding south the shore trends generally south-west, is marked by many deep inlets with bold bluffs and by mountains. At the south-east corner is Speke gulf, and at the south-west corner Emin Pasha gulf. Here the coast is barren and hilly, while long ridges of rock run into the lake.

The largest island in the lake, Ukerewe, north of Speke gulf, is almost a peninsula. It is uninhabited, wooded and hilly, rising 650 ft. above the lake. At the north-west corner of the lake is the Sessi archipelago, consisting of sixty-two islands. The largest island in this group is Bugala. Most of these islands are densely forested, and some of them attain considerable elevation. Their scenery is of striking beauty. Buvuma island is at the entrance of Napoleon gulf and there are numerous other islands, of which the chief are Bugaia, Lolui, Rusinga and Mfwangani. The islands are of ironstone formation overlying quartzite and crystalline schists.

Rivers.—The Kagera, the largest and most important of the lake affluents, rises east of Lake Kivu, and enters the west side of the lake just north of 1° S. It is the most remote head-stream of the Nile (*q.v.*). The other rivers entering Lake Victoria from the west are the Katonga and Ruizi, both north of the Kagera. Between the Katonga and the Nile outlet, the rivers which rise close to the lake drain away northward, the watershed being the lake shore. On the north-east several streams reach the lake—notably the Sio, Nzoia and Lukos (or Yala). On the east the Mara Dabagh enters the lake between 1° and 2° S. It is, next to the Kagera, the largest of the lake tributaries. On the southern shores a number of short rivers drain into the lake. The only outlet of the lake is the Nile (*q.v.*).

The area drained by the lake covers, with the lake itself, 92,240 sq. miles. A detailed survey was made of the lake by Sir William Garstin. (*See* British Bluebook, *Egypt,* 1902.)

Discovery and Exploration.—The quest for the Nile sources led to the discovery of the lake by J. H. Speke in 1858. In 1862 Speke and J. A. Grant partially explored the north-west shore, leaving the lake at the Nile outlet. It was circumnavigated by H. M. Stanley in 1874. The invitation sent by King Mtesa of Uganda through Stanley to the Christian missionaries led to the despatch from England in 1876 of the Rev. C. T. Wilson, to whom we owe our first detailed knowledge of the lake. Wilson and Lieut. Shergold Smith, R.N., made, in 1877, the first voyage across the lake. Lieut. Smith and O'Neill were in the same year murdered on Ukerewe island. In 1889 Stanley further explored the lake, discovering Emin Pasha gulf. In 1890 the ownership of the lake was divided by Great Britain and Germany, the first degree of south latitude being taken as the boundary line. The southern portion, which fell to Germany, was visited and described by scientists of that nation. At the instance of the British Foreign Office a survey of the northern shores was carried out in 1899–1900 by Commander B. Whitehouse, R.N. The same officer, in 1903, undertook, in agreement with the German government, a survey of the southern shores. There is steamer service on the lake, weekly from Kisumu to Uganda ports and back, weekly round the lake and fortnightly between the Sessi islands and Entebbe. The lake is connected with the coast by rail from Kisumu to Mombasa, and there is a line from Jinja northwards to Namasagali. The lake is now entirely surrounded by British territory, the southern half being in Tanganyika territory, the northern in the Uganda protectorate and a small portion of the

east coast is within the confines of Kenya colony.

BIBLIOGRAPHY.—*See* NILE and UGANDA and the British Bluebook Egypt No. 2 (1904). This report, which is mentioned above also summarizes the information of previous travellers, whose works are quoted. In 1908 the British Admiralty published a chart of the lake (scale 4 in. to the mile). *See* also E. G. Ravenstein, "The Lake-level of the Victoria Nyanza," *Geog. Journ.* Oct. 1901; Sir H. H. Johnston, *The Uganda Protectorate* (London, 1902).

VICTORIA FALLS, rivalled only by Niagara in grandeur, form the most remarkable feature of the river Zambezi, Central Africa. The falls are about midway in the course of the Zambezi in 17° 51′ S., 25° 41′ E. For a considerable distance above the falls the river flows over a level sheet of basalt, its valley bounded by low and distant sandstone hills. Its clear blue waters are dotted with numerous tree-clad islands. These islands increase in number as the river, without quickening its current, approaches the falls, whose nearness is indicated only by a veil of spray. At the spot where the Zambezi is at its widest—over 1,860 yds.—it falls abruptly over the edge of an almost vertical chasm with a roar as of continuous thunder, sending up vast columns of vapour.

The chasm, extending over the whole breadth of the river, is about half the total width of Niagara but it is more than twice the depth, varying from 256 ft. at the right bank to 343 ft. in the centre. Unlike Niagara the water does not fall into an open basin but is arrested at a distance of from 80 to 240 ft. by the opposite wall of the chasm. Both walls are of the same height, so that the falls appear to be formed by a huge crack in the bed of the river. The only outlet is a narrow channel cut in the barrier wall at a point about three-fifths from the western end of the chasm, and through this gorge, not more than 100 ft. wide, the whole volume of the river pours for 130 yd. before emerging into an enormous zigzag trough (the Grand Cañon) which conducts the river past the basalt plateau. The tremendous pressure to which the water is subjected in the confinement of the chasm causes the perpetual columns of mist which rise over the precipice.

The fall is broken by islands on the lip of the precipice into four parts. Close to the right bank is a sloping cataract 36 yd. wide, called the Leaping Water, then beyond Boaruka Island, about 300 yd. wide, is the Main Fall, 473 yd. broad, and divided by Livingstone Island from the Rainbow Fall 535 yd. wide. At both these falls the rock is sharp cut and the river maintains its level to the edge of the precipice. At the left bank of the river is the Eastern Cataract, a millrace resembling the Leaping Water. From opposite the western end of the falls to Danger Point, which overlooks the entrance of the gorge, the escarpment of the chasm is covered with great trees known as the Rain Forest; looking across the gorge the eastern part of the wall (the Knife Edge) is less densely wooded. At the end of the gorge the river has hollowed out a deep pool, named the Boiling Pot. It is some 500 ft. across; its surface, smooth at low water, is at flood-time troubled by slow, enormous swirls and heavy boilings. Thence the channel turns sharply westward, beginning the great zigzag mentioned. This grand and gloomy cañon is over 40 m. long. Its almost perpendicular walls are over 400 ft. high, the level of the escarpment being that of the lip of the falls. A little below the Boiling Pot, and almost at right angles to the falls, the cañon is spanned by a bridge (completed in April 1905) which forms a link in the Cape to Cairo railway scheme. This bridge, 650 ft. long, with a main arch of 500 ft. span, is slightly below the top of the gorge. The height from low-water level to the rails is 420 ft.

The volume of water borne over the falls varies greatly, the level of the river in the cañon sinking as much as 60 ft. between the full flood of April and the end of the dry season in October. When the river is high the water rolls over the main falls in one great unbroken expanse; at low water (when alone it is possible to look into the grey depths of the great chasm) the falls are broken by crevices in the rock into numerous cascades.

The falls are in the territory of Rhodesia. They were discovered by David Livingstone on the 17th of November 1855, and by him named after Queen Victoria of England. Livingstone approached them from above and gained his first view of the falls from the island on the lip now named after him. In 1860 Livingstone, with Dr. (afterwards Sir John) Kirk, made a careful investigation of the falls, but until the opening of the railway from Bulawayo (1905) there were but few visitors. The land in the vicinity of the falls is preserved by the Rhodesian government as a public park.

BIBLIOGRAPHY.—*See* Livingstone's *Missionary Travels and Researches in South Africa* (1857) for the story of the discovery of the falls, and the *Popular Account of Dr. Livingstone's Expedition to the Zambesi and its Tributaries 1858–1864* (1894) for a fuller description of the falls and a theory as to their origin. In the *Geographical Journal* Jan. 1905, A. J. C. Molyneux on "The Physical History of the Victoria Falls," gives photographs and bibliography. Consult also "The Gorge and Basin of the Zambesi below the Victoria Falls," by G. W. Lamplugh in the *Geog. Jour.* (1908), vol. xxxi.

VICTORIA REGIA, the giant water-lily of the Amazon, the leaves of which may be 2 metres across, with the edges turned up to a height of several centimetres. On the lower surface, the projecting ribs bear spines. The flowers are large and pink. The plant is widely cultivated and has been introduced into Java (there is a fine specimen in the Buitenzorg gardens) and elsewhere. The roasted fruit is eaten in Brazil. There are two other species of the genus, also South American. (*See* WATER-LILY.)

VICTORINUS, GAIUS MARIUS (4th century A.D.), Roman grammarian, rhetorician and Neoplatonic philosopher, an African by birth, lived during the reign of Constantius II. He taught rhetoric at Rome (one of his pupils being Jerome) and in his old age became a convert to Christianity. His conversion is said to have greatly influenced that of Augustine. When Julian published an edict forbidding Christians to lecture on polite literature, Victorinus closed his school. A statue was erected in his honour as a teacher in the Forum Trajanum.

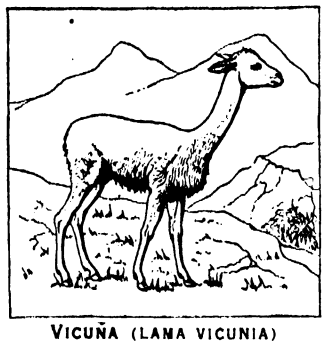
The treatise *De Definitionibus* (ed. T. Stangl in *Tulliana et Mario-Victoriniana,* Munich, 1888) is probably by him and not by Boëtius, to whom it was formerly attributed. His manual of prosody, in four books, taken almost literally from the work of Aphthonius, is extant (H. Keil, *Grammatici Latini,* vi.). It is doubtful whether he is the author of certain other extant treatises attributed to him which will be found in Keil. His commentary on Cicero's *De Inventione* (in Halm's *Rhetores Latini Minores,* 1863), is very diffuse, and is itself in need of commentary. His extant theological writings will be found in J. P. Migne, *Cursus Patrologiae Latinae,* viii.

Schmid, *Marius Victorinus Rhetor und seine Beziehungen zu Augustin* (Kiel, 1895); Gore in *Dictionary of Christian Biography,* iv.; M. Schanz, *Geschichte der römischen Litteratur,* iv. 1 (1904); Teuffel, *Hist. of Roman Literature* (Eng. trans., 1900), 408.

VICTOR-PERRIN, CLAUDE, DUKE OF BELLUNO (1764–1841), marshal of France, was born at La Marche (Vosges) on Dec. 7, 1764. In 1781 he entered the army as a private soldier, and after ten years' service he received his discharge and settled at Valence. Soon afterwards he joined the local volunteers, and distinguishing himself in the war on the Alpine frontier, in less than a year he had risen to the command of a battalion. He served at Toulon (1793), in the Italian campaign of 1796–97, in La Vendée, and then in Italy at Marengo. In 1802 he was governor of the colony of Louisiana for a short time, in 1803 he commanded the Batavian army, and in 1805–6 was French plenipotentiary at Copenhagen. On the outbreak of hostilities with Prussia he joined the V. army corps (Marshal Lannes) as chief of the general staff. He distinguished himself at Saalfeld and Jena, and after Friedland where he commanded the I. corps Napoleon gave him the marshalate. After the peace of Tilsit he became governor of Berlin, and in 1808 he was created duke of Belluno. In the same year he was sent to Spain, where he took a prominent part in the Peninsular War (especially at Espinosa, Talavera, Barrosa and Cadiz), until his appointment in 1812 to a corps command in the invasion of Russia. Here his most important service was in protecting the retreating army at the crossing of the Beresina. He took an active part in the wars of 1813–14, till in February of the latter year he had the misfortune to arrive too late at Montereau-sur-Yonne. The result

was a scene of violent recrimination and his supersession by the emperor, who transferred his command to Gérard.

Victor now transferred his allegiance to the Bourbons, and in Dec. 1814 received from Louis XVIII. the command of the second military division. In 1815 he accompanied the king to Ghent, and on the second restoration he was made a peer of France. He was war minister in 1821–23. In 1830 he was major-general of the royal guard, and after the revolution of that year he retired altogether into private life. He died in Paris on March 1, 1841.



His papers for the period 1793–1800 have been published (Paris, 1846).

VICUÑA, a term applied both to a distinctive variety of wool, and also to a special kind of "finish" given to certain varieties of woollen textures. Vicuña wool is the fleece obtained from the vicuña (*q.v.*), a wild relative of the llama (*q.v.*) inhabiting the mountainous districts of Chili and Peru. This type of wool is distinguished for its remarkably long, fine, soft and lustrous character for which it is greatly prized. These properties adapt it eminently for the production of woollen and worsted textures that require a soft and full "handle" or "feel," and also for the development of a "nap."

Vicuña fabrics comprise several varieties of woollen and worsted textures, which are of the character of serge (*q.v.*), excepting that they are more supple, softer and fuller, and of a more subdued lustre than true serge textures. This is partly owing to the different character of wool employed in their manufacture, as well as to the method of finishing. Like serges, also, vicuña fabrics are usually based on the simple twill weave structures and employed as dress and costume materials and suitings.

Vicuña fabrics comprise two distinct types of textures, viz.: (1) simple structures for the lighter and medium textures suitable for women's wear, and light suitings and coatings for men's summer wear; and (2), double-cloth structures for the heavier and stronger textures suitable for men's overcoatings. This class is produced either from two-fold worsted both for warp and weft, or from two-fold worsted warp, and single worsted or woollen weft, for softer textures. One example of the latter class is woven with the 5-end venetian (double-stitch 5-end warp satin) weave, and a 10-end sateen (weft-face) back; while a second example is woven with the four-end ($\frac{2}{2}$) twill face weave, and with the plain weave on the back, which produces a relatively stronger and better wearing cloth.

To obtain the true "vicuña" handle, the routine of the finishing process is varied to suit the character of yarn employed, the weave structure and the "setting" of the fabric, *i.e.*, the number of warp and weft threads per inch in the fabric. The procedure then consists of knotting and mending; crabbing or blowing with steam, to set the fabric; scouring; milling; dyeing; washing-off; tentering; raising (wet); cutting; brushing; steaming or dewing; shrinking and pressing (rotary machine). An alternative method is to raise the cloth previous to milling. (H. N.)

VICUÑA (LAMA VICUNIA)

VICUÑA or **VICUGNA,** one of the two wild South American representatives of the camel-tribe still surviving (*see* TYLOPODA). From its relative the guanaco, the vicuña (*Lama vicunia*) differs by its inferior stature, more slender build, shorter head, and the absence of bare callosities on the hind limbs. The colour is orange-red. Vicuñas live in herds on the bleak and elevated parts of the mountain range bordering the region of perpetual snow, in various parts of Peru, in southern Ecuador, and southwards to central Bolivia. The wool is delicate and soft and highly valued for weaving.

VIDA, MARCO GIROLAMO (*c.* 1489–1566), Italian scholar and Latin poet, was born at Cremona shortly before the year 1490 and died at Alba on Sept. 27, 1566. He entered the order of the Canonici Regolari Lateranensi, and made a reputation by two Latin poems, on the *Game of Chess* and the *Silkworm*. On the strength of this he went to Rome, when Leo X. on his succession (1513) gave him a priory and set him to compose a poem on the life of Christ. This *Christiad* is his most famous work. Between 1520 and 1527 he produced another hexameter poem on the *Art of Poetry* (ed. Baldi, Würzburg, 1881). In 1532 he became bishop of Alba.

See the *Life* by Lancetti (Milan, 1840).

VIDAME, a French feudal title. The vidame (Lat. *vice-dominus*) was originally, like the avoué (*advocatus*), an official chosen by the bishop of the diocese, with the consent of the count (*see* ADVOCATE). During the Carolingian epoch, *advocatus* and *vice-dominus* were interchangeable terms; it was only in the 11th century that they became differentiated, the title of avoué being commonly reserved for nobles charged with the protection of an abbey, that of vidame for those guarding an episcopal see. In the 12th century the office of vidame, like that of avoué, had become an hereditary fief. As a title, however, it was less common and less dignified than that of avoué. The *advocati* were often great barons who added their function of protector of an abbey to their own temporal sovereignty; the vidames were usually petty nobles, who exercised their office in strict subordination to the bishop. Their chief functions were: to protect the temporalities of the see, to represent the bishop at the count's court of justice, to exercise the bishop's temporal jurisdiction in his name, and to lead the episcopal levies to war.

See A. Luchaire, *Manuel des institutions françaises* (Paris, 1892); Du Cange, *Glossarium* (ed. Niort, 1887), s. "Vice-dominus"; A. Mallet, "Étude hist. sur les avoués et les vidames," in *Position des thèses de l'École des chartes* (an. 1870–72).

VIDIN (formerly written WIDIN or WIDDIN), a fortified river-port and capital of a department in the extreme N.E. of Bulgaria; on the right bank of the Danube, near the Yugoslav frontier. Pop. (1926) 19,115, including about 3,000 Turks and 1,500 Spanish Jews—descendants of refugees who fled hither from the Inquisition in the 16th century. Vidin is an episcopal see and the headquarters of a brigade. A steam ferry connects it with Calafat, on the Rumanian bank of the Danube, and there is a branch railway to the main line Sofia-Lom. The old town, containing several mosques and synagogues and a bazaar, preserves its oriental appearance. There is a modern cathedral, a school of viticulture and a high school, besides an ancient clock-tower and the palace (*Konak*) formerly occupied by the Turkish pashas. Vidin exports cereals and fruit, and is locally celebrated for its gold and silver filigree. It has important fisheries and manufactories of spirits, beer and tobacco.

Vidin stands on the site of the Roman town of Bononia in Moesia Superior. It is a fortress of great natural strength owing to the marshes which surround it. In the 14th century it was the seat of an independent tsardom, which was overthrown by the Turks in 1396. Under the Turks it was the seat of a pashalik, which under Pasvanoglu (1794–1807) was practically independent.

VIDOCQ, FRANÇOIS EUGENE (1775–1857), French detective, was born at Arras in 1775 (or possibly 1773). After an adventurous youth he joined the French army, where he rose to be lieutenant. At Lille he was sentenced to eight years' hard labour, and sent to the galleys at Brest, whence he escaped twice but was recaptured. For the third time he escaped, and lived for some time in the company of thieves and other criminals in Paris and elsewhere, making a careful study of their methods. He then offered his services as a spy to the Paris police (1809). Eventually Vidocq was made chief of the reorganized detective department of the Paris police, with a body of ex-convicts under his immediate command. Vidocq possessed unbounded energy and a real genius for hunting down criminals. In 1827 he retired and started a paper-mill, the work-people in which were drawn entirely from ex-convicts. The venture was a failure, and in 1832 Vidocq re-entered the police service and was employed mainly in political work. Anxious to get back to his old detective post he himself foolishly organized a daring theft. His real part in the matter became known, however, and he was dismissed from service. He died in poverty. Several volumes have been published under

his name, the best known of which is *Mémoires de Vidocq* (1828). It is, however, extremely doubtful whether he wrote any of them.

See Charles Ledru, *La Vie, la mort et les derniers moments de Vidocq* (1857).

VIDYASAGAR, ISWAR CHANDRA (1820–1891), writer and social reformer of Bengal, was born at Birsinha in the Midnapur district in 1820, of a Kulin Brahman family. He was removed to Calcutta at the age of nine, was admitted into the Sanskrit College, and carried on his studies in the midst of privations and extreme poverty. In 1839 he obtained the title of *Vidyasagar* (="Ocean of learning") after passing a brilliant examination, and in 1850 was appointed head pundit of Fort William College. In 1846 appeared his first work in Bengali prose, *The Twenty-Five Tales of a Betal.* This was succeeded by his *Sakuntala,* 1855, and by his great work, *The Exile of Sita,* 1862.

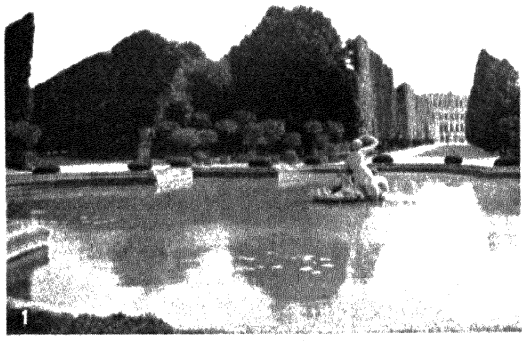
As a social reformer and educationist, too, Iswar Chandra made his mark. He associated himself with Drinkwater Bethune in the cause of female education; and the management of the girls' school, called after Bethune, was entrusted to him in 1851. And when Rosomoy Datta resigned the post of secretary to the Sanskrit College of Calcutta, a new post of principal was created, and Iswar Chandra was appointed to it. He simplified the method of learning Sanskrit; and thus rendered a great service to Sanskrit learning of that ancient tongue among his countrymen. Under the education scheme of 1854 he established aided schools in Bengal. In 1858 he resigned his appointment under government. He became manager of a private college at Calcutta.

But he now turned to practical reform. He had discovered that the ancient Hindu scriptures did not enjoin perpetual widowhood, and in 1855 he startled the Hindu world by his work on the *Remarriage of Hindu Widows.* Such a work, from a learned and presumably orthodox Brahman, aroused a storm of indignation. He appealed to the British government to declare that the sons of remarried Hindu widows should be considered legitimate heirs. The act was passed in 1856, and some years after Iswar Chandra's own son was married to a widow. In the last years of his life Iswar Chandra wrote works against Hindu polygamy. He was as well known for his lavish charity and wide philanthropy as for his educational and social reforms. He received the C.I.E. in 1880. He died on July 29, 1891. (R. C. D.)

VIEBIG, CLARA (1860–), German novelist, was born on July 17, 1860, at Trier, and educated at Düsseldorf and at the Berlin high school of music. She married in 1896 Fritz Cohn, and has one son. She began by writing stories of the Eifel country, in which she was born, *Kinder der Eifel* (1897). Among the most famous of her earliest novels was *Das schlafende Heer* (1904), the scene of which is laid in German Poland; in this book there is no extenuation of the faults of either Germans or Poles. Among her other works are: *Einer Mutter Sohn* (1906), *Töchter der Hekuba* (1917), *Unter dem Freiheitsbaum* (1924), and *Die Passion* (1926).

VIEIRA, ANTONIO (1608–1697), Portuguese Jesuit, writer and orator, was born at Lisbon on Feb. 6, 1608. He went with his parents to Brazil in 1615, was educated by the Jesuits at Bahia, and entered the order, receiving the priesthood in 1635. He at once made his mark as a preacher. He was sent, in 1640, with the viceroy's son to congratulate John IV. of Portugal on his accession, and was employed on various important diplomatic missions to England, France, Holland and Italy. Vieira was full of new and progressive ideas and advocated in a series of important pamphlets the abolition of the distinction between Old and New Christians, the reform of the procedure of the inquisition, and the admission to Portugal of Jewish and foreign traders.

As a young man he had determined to serve the negro slaves and the native Indians, and on his return in 1653 he resumed his great missionary work among the Indians. He was hindered in every possible way by the Colonial authorities, and decided that the only way to ensure the success of his mission was to secure the withdrawal of the Indians from the jurisdiction of the governors and to place them under that of the Society. In 1654 he sailed to Lisbon, and there secured from the king the necessary decrees. During the next six years he organized the new control and organized the missionaries. But his enemies among the colonists, who complained that the supply of slaves had decreased, and among the other religious orders shut out from the missions, secured his exile to Portugal. King John was dead, and he had no protector against the inquisition when he was charged with heretical teaching in some of his strange books, notably in the *Clavis Prophetarum.* He was imprisoned for two years (1665–67), and on his release was prohibited from writing, teaching and preaching. On the accession of Pedro II. it was determined that he should go to Rome to procure the revision of the sentence. There Clement X. invited him to preach before the college of Cardinals, and he became confessor to Queen Christina of Sweden and a member of her literary academy. At the request of the pope he drew up a report of 200 pages on the inquisition in Portugal, with the result that after a judicial inquiry Pope Innocent XI. suspended it for five years (1676–81). Ultimately Vieira returned to Portugal with a papal bull exempting him from the jurisdiction of the grand inquisitor, and in Jan. 1681 he embarked for Brazil. He resided in Bahia and in 1687 became superior of the province. He died on July 18, 1697.

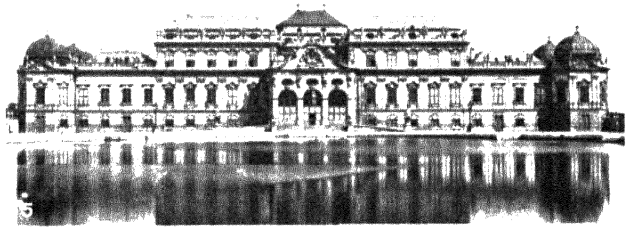


BIBLIOGRAPHY.—Vieira's writings include: *Sermoes* (Sermons) (15 vols., Lisbon, 1679–1748), and many subsequent but incomplete editions; Span., Ital., Ger. and French translations have gone through several editions, *Historia do Futuro* (Lisbon, 1718); this and the *Quinto Imperio* and the *Clavis Prophetarum* seem to be in essence one and the same book in different redactions. *Cartas* (Letters) (3 vols., Lisbon, 1735–46). *Noticias reconditas do modo de proceder a Inquisicão de Portugal com os seus presos* (Lisbon, 1821). The *Arte de Furtar* published under Vieira's name is not his. A badly edited edition of Vieira's works in 27 vols. appeared in Lisbon, 1854–58; there are unpublished mss. of his in the British Museum and Bibliothèque Nationale; and a bibliography will be found in Sommervogel, *Bibliothèque de la compagnie de Jésus,* viii. 653–85.

See also André de Barros, *Vida* (Lisbon, 1746), a Jesuit panegyric; D. Francisco Alexandre Lobo bishop of Vizeu, "Historical and Critical Discourse," *Obras* (Lisbon, 1849), vol. ii., a valuable study; João Francisco Lisboa, *Vida* (5th ed., Rio, 1891), he is unjust to Vieira, but may be consulted to check the next writer; Abbé E. Carel, *Vieira, sa vie et ses oeuvres* (Paris, 1879); Luiz Cabral, *Vieira, biog., caractère, éloquence* (Paris, 1900); *ibid., Vieira pregador* (2 vols., Oporto, 1901); Sotero dos Reis, *Curso de litteratura Portugueza e Brazileira,* iii. 121–244.

VIELLE, a French term, derived from Lat. *fidicula,* embracing two distinct types of instruments: (1) from the 12th to the beginning of the 15th century bowed instruments having a box-soundchest with ribs; (2) from the middle or end of the 15th century, the hurdy-gurdy (*q.v.*). The most common shape given to the earliest vielles in France was an oval, which with its modifications remained in favour until the guitar-fiddle, the Italian lyra, asserted itself as the finest type, from which also the violin was directly evolved.

VIENNA, the capital of the Austrian republic, has the status of an autonomous federal province and its municipal council fulfils the functions of a provincial diet. The city lies at the eastern foot of the Wiener Wald, on the right bank of the Danube within easy reach of a number of contrasted physical and economic regions. Here many of the great routes from north to south and west to east intersect while close at hand runs the linguistic frontier between German, Slav and Magyar. From the multiplicity of these contacts Vienna acquired a cultural leadership that placed it in the forefront of European cities. Only an arm of the river, the Danube canal, passes through Vienna. The main river was developed between 1870 and 1877, and now has a quay length on the right bank of about 9 m. with accommodation in a winter harbour, Freudenau, to shelter above 500 barges of 500–700 tons cargo capacity. Navigation is possible for about 300 days per year. The new channel has an average width of 915 ft.; bordering its left bank is a free flood space about ¼ m. in width, separated by a dam from houses that stretch to the old course of the Danube.



The city is divided into 21 districts of which the Inner Town on the right bank of the Danube canal is the nucleus. The fortifications which girdled this old town were removed in 1858–60 and replaced by a magnificent boulevard—the Ringstrasse—2 m. long and 150 ft. in width, planted with four rows of trees and lined with splendid buildings and monuments. Near the centre of this inner city is the cathedral of St. Stephen, a Gothic building

SCENES IN VIENNA

1. Schönbrunn Palace and gardens on the outskirts of Vienna. Used as a summer residence by the Imperial family
2. The Imperial Museums of Fine Arts and Natural History. Built 1870–89, the museums are similar in their detail
3. A section of the Parliament building. The Grecian style has been adapted to modern requirements
4. Entrance to one of the many amusement parks in Vienna. A colossal
5. The Hofburg (Imperial Palace) a huge complex of buildings of various styles and epochs. The oldest part dates from the 13th century
6. The Vienna Opera house. Interior vies in sumptuousness with the Opera house of Paris. Built 1861–69
7. Spire of St. Stephen's Cathedral towering 450 ft. in the air and regarded as one of the finest Gothic spires in the world. Rebuilt 1860–64

dating mainly from the 14th and 15th centuries, but incorporating fragments of the original 12th century edifice, destroyed by fire 1193. Among its many impressive features may be mentioned the lofty tower (450 ft.), rebuilt in 1860–64, the catacombs, the groined ceiling, the 35 marble altars and the sarcophagus of Frederick III. This district is rich in Baroque buildings, many occupied by Government departments, banks and other commercial organizations, for it is gradually ceasing to be a residential neighbourhood; here too are situated the larger and most fashionable shops, particularly in the *Graben* thoroughfare.

South-west of the cathedral and near the Ring is the Hofburg, a huge complex of buildings of various periods and styles enclosing a number of courtyards, the oldest parts dating from the 13th century but including extensive additions since 1887. As a former imperial palace it abounds in magnificently appointed private and State apartments, numerous valuable collections and the National Library of about 1,200,000 volumes, 34,000 mss., 91,000 maps, 81,000 papyri, including the famous "Papyrus Rainer," and a large collection of musical and dramatic works. The Hofburg is separated from the Ring by handsome and spacious parks, the Hofgarten and Volksgarten. Other notable buildings in the old town include the 14th century Gothic Augustine and Maria Stiegen churches, the Minorite church of similar date and style containing a remarkable mosaic of Leonardo da Vinci's "Last Supper" by Raffaeli, the richly-frescoed Baroque churches of St. Peter (1702–13) and the university (1625–31), the Capuchin church, the 13th century Schotten church (restored 1828–83), the church of St. Ruprecht first built in 740 and the old Rathaus.

Beyond the imposing Ring and grouped around it are a number of impressive buildings and parks. Opposite the Hofburg stand the museums of natural history and art, two domed Renaissance buildings dating from 1872–81, identical in construction but separated by gardens containing the Maria Teresa monument. Adjoining the museums to the west is the palace of justice (1881) burned during riots in 1927, and the houses of parliament (1883) in modified Grecian style. Beyond these stands the new *Rathaus* (1873–83), a very large and lavishly decorated building separated from the Ring by the *Rathaus* park. This edifice is in modern Gothic style which is a striking contrast to the Classical and Renaissance styles so strongly represented in Viennese architecture. To the north stands the university, an example of Renaissance style (1873–74), even larger than the *Rathaus*. The university, the oldest German foundation (1365), has done much to raise Vienna to its high position as one of the leaders of culture amongst the European nations and its medical faculty is of world-wide reputation. The university library with 1,060,000 volumes is very well-equipped.

Other important buildings of the *Ringstrasse* include the Opera (1861–69), in French early Renaissance style. On the eastern side lies the Town park, rich in monuments. The Inner town and its immediate neighbourhood is still, unlike the older parts of most European towns, the fashionable quarter, containing many of the embassies and legations, the government offices and the principal hotels; it is also the richest in handsome buildings.

Across the Danube canal and between it and the main stream lie Leopoldstadt and Brigittenau, the only districts on the left bank of the canal. The former is the chief commercial quarter and is still inhabited to a great extent by Jews. Around the Ring stretches a girdle of nine inner suburbs once bound to the inner town by a second line of fortifications (1706) known as the Lines. These were rased in 1893 and a second wide boulevard (*Gürtelstrasse*) follows their course around the city.

Vienna is richly endowed in museums, picture-galleries and other marks of cultural leadership, stored with masterpieces representative of all types, masters and periods In addition it possesses many private exhibitions of note. Every form of intellectual development, artistic, musical and scientific in all its branches, has

its representative collections supplemented by large libraries belonging to the state, city, private societies or monastic orders. In itself it is a museum of architecture and a city of open spaces and parks, amongst which may be mentioned the Prater (2,000 ac.), a wooded park on the east side of the river between the Danube and the Danube canal.

Situated at an altitude of about 550 ft. above sea-level, it has a healthy and agreeable climate. The mean annual temperature is 49·4° F and the range about 40° F. The climate is changeable but stimulating, liable to rapid falls of temperature and sudden storms especially in spring and autumn, and the rainfall amounts to 27 in. a year. Its water supply is drawn from the Alps by aqueducts.

Though it has suffered loss both in population and trade by the war Vienna has gathered to itself much of the industrial life of Austria and still holds a high place amongst the world's cities as a producer of artistic fancy goods, notably leather, jewellery, *objets d'art*, silks, clothing, millinery and other luxury goods. In addition it has manufactures of optical instruments, metal wares, heavy iron and steel machinery and rolling stock, furniture, paper, beer, textiles and chemicals and is an important publishing centre and also has a thriving film industry. As a transit centre it is recovering its old importance. The revival of the Industrial Fair, electrification of the city belt railway, the transformation of palaces, even parts of the Hofburg, into offices, shops and public halls, of old imperial gardens into public parks, schemes of housing, these and many other activities for ultimate social welfare are indicative of a progressive spirit somewhat foreign to popular ideas of the Viennese.

The population of Vienna numbered in 1923 1,866,147 inhabitants on an area of 107 sq.m., compared with the population of 2,031,498 in 1910 and 1,841,326 in 1920. By virtue of its situation the population of Vienna has always been of a very cosmopolitan character with a preponderance of the German element. The break up of the empire caused many of the Hungarians, Czechs and other Slavs to leave the city but increased the proportion of Jews, which rose from 9% (1910) to 11%.

HISTORY

Under the name of Vindobona Vienna was a Celtic settlement and later Roman garrison town. The Roman fortress stood on the small eminence bounded N. by the modern Salzgries, E. by the Rotenturmstrasse, S. by the Graben and W. by the Tiefer Graben. Here Marcus Aurelius is supposed to have died (A.D. 180). During the period of the Great Migrations and the succeeding centuries its traces were lost; but tradition ascribes the foundation of the St. Peter's Church to Charlemagne (A.D. 800), the Church of St. Rupprecht being older still. After the establishment of the Ostmark (*see* AUSTRIA) it revived. In 1137 "Wienne" is mentioned as a "civitas."

In that year Henry Jasomirgott chose it as capital of the duchy of Austria, establishing his court Am Hof outside the old walls. The cathedral (Stefanskirche) was founded in the same year; a commercial town grew up round it, and a ghetto round the present Judenplatz. Later, under the Babenberger, Vienna became an important trading centre, largely thanks to new relations between East and West established by the Crusades. It was also the centre of a brilliant court life and of an important school of lyric poetry (Walter von der Vogelweide, etc.), while the great epics of the *Niebelungen* and the *Gudrun* were composed near its walls. By the end of this period it had grown to about the size of the present Innere Stadt; many monastic orders were established here, and many churches built; although owing to the numerous fires and later rebuilding, none of these have kept their original form.

The Habsburg Rule.—The first Habsburg to enter Vienna as ruler, Albert, came into immediate conflict with the city, which he invested and forced to capitulate, annulling many of its privileges. The era of the earlier Habsburgs was generally unfortunate; the plague, the visitations of robbers and condottieri, the financial crisis and monetary depreciation, and the ceaseless internecine wars of the Habsburgs hit the city hard; yet it remained a wealthy and important centre, and some of the Habsburgs were its generous patrons, notably Rudolph IV., who founded the university (1356) and did much for the reconstruction of the Stefanskirche. Under Frederick IV. Vienna at first preserved neutrality; but it was the centre of the movement against Frederick led by Eiczing, and after Archduke Albrecht had twice stormed the city in 1458, a radical opposition was formed, and Frederick was besieged in the Hofburg (1462). Frederick never liked Vienna, residing for preference in Wiener Neustadt, and later in Linz; Matthias Corvinus of Hungary, however, after taking Vienna, made it his residence. Maximilian I. showed an equal lack of interest in Vienna; and Ferdinand I., on arriving in Austria, found Vienna entirely old-fashioned. Another great fire raged in 1525, and in 1529 the city had to stand a siege from the Turkish troops. The suburbs were deserted, and more and more inhabitants crowded into the old town. Rudolph II. resided in Prague; but Ferdinand II. returned to Vienna, which remained the residence of the Habsburgs.

The spiritual forces of the Counter-Reformation were what gave Vienna its most characteristic aspect. The period of early baroque saw the foundation of a number of churches—the Franciscans, the Jesuits, the Capucines and many more, including a number outside the city walls, such as the Barmherziger Brüder, the Paulaner, Schwarzspanier and the Barnabiten; with a smaller output of other buildings such as the Archbishop's palace. The second siege of Vienna by the Turks (1683) was the indirect cause of the appearance of the characteristic Viennese cafés, almost simultaneously with another no less characteristically Viennese product of the Orient—the lilac, first planted in Vienna, to spread thence over Western Europe. The disappearance of the Turkish danger ushered in a time of rapid expansion; the Hofburg was rebuilt, its library and stables constructed, together with a number of buildings in sumptuous baroque style: the Karlskirche, the Peterskirche, the Reichskanzlei, Hofreitschule and Bürgerliches Zeughaus, the Pestsäule in the Graben, the Josefssäule in the Hoher Markt, the Lichtenstein, Starhemberg, Schwarzenberg, Kinsky, Esterhazy and Prince Eugen palaces. The Belvedere palace was built 1717–24; Schönbrunn was begun about 1695, but not finished till half a century later. The architecture of the later 18th century is by comparison sober and practical.

The reign of Francis I. created the typical Viennese of tradition; frivolous, non-political, discontented, easy-going; "Alt-Wien" with its waltzes, its Prater and its political spies. The revolution of 1848 showed that even the Viennese were not patient for ever. Its main driving forces in Vienna were the students and the workmen of the suburbs, in which a dense industrial population had begun to grow up with the development of machinery. Again Vienna suffered a siege; this time from the troops of its own emperor, by whom it was quickly reduced. The modern period under Francis Joseph saw another transformation. The old ramparts and glacis were levelled, the great Ringstrasse built in their place. Round it a number of great buildings were erected in various styles; the Opera, the new Rathaus, the Parliament, the Burgtheater, the new university and the Votivkirche. In the latter half of the 19th century the population of Vienna grew with great rapidity. The inner ring of suburbs was entirely incorporated with the city, which stretched out beyond the "Vorortlinie" to the outer ring, swallowing up many of the vineyards on which much of Vienna's old fame had rested. The municipality again became a powerful political force, and once again came into conflict with the emperor, who had twice refused to confirm the appointment of Karl Lueger as Burgomaster of Vienna.

After the World War and revolution of 1918, which caused untold suffering in Vienna, partially relieved by the general effort of many foreign charitable organizations, the power passed to the Social Democratic party. Vienna became capital of the new Austrian republic, receiving the status of a province in 1921. The

Social Democratic municipality embarked on a far-reaching and ambitious programme of social reform, which included a serious attempt to grapple with the very acute housing problem.

VIENNA, CONGRESS OF (1814–1815). The fall of Napoleon left the disposition of his empire to the four Powers who had overthrown him—Austria, Prussia, Russia and Britain. Other countries, of whom Spain, Portugal and Sweden were the most important and signed the Treaties of Paris, May 30, 1814, had shared in this task, but the four greater Powers were bound together by a special alliance (Treaty of Chaumont, March 1, 1814). Thus though the treaties with France stipulated that all countries who had taken part in the war should send plenipotentiaries to a congress at Vienna, the four Powers meant to make the decisions themselves, and, as they could not agree at Paris, bound France by a secret article of the treaties to recognize these decisions at a future date.

The Delegates.—Thus the meeting at Vienna, where representatives began to arrive towards the end of September, was meant to be merely a convenient assembly to ratify the decisions of the "four." Nevertheless, all Europe sent its most important statesmen. Metternich, principal minister of Austria since 1809, naturally represented his Emperor Francis II., a stubborn man who sometimes had a policy of his own. Wessenberg, an ambassador, Gentz, a journalist of great capacity, who acted as secretary of the congress, and Hudelist, a permanent official, were his principal assistants. The brilliant, but wayward and emotional, Alexander I. of Russia directed his own diplomacy. His servants who were mainly foreigners, included Capo d' Istria (a Greek), Stein (the regenerator of Prussia), Nesselrode (of German blood), Laharpe (his Swiss tutor), and Czartoryski (a Pole). The weak Frederick William III. of Prussia had as his principal minister Prince von Hardenberg, who had lost credit owing to physical infirmities, but was ably seconded by the celebrated Wilhelm von Humboldt and some efficient civil servants. Great Britain was represented by the foreign minister Lord Castlereagh, the creator of the Alliance of Chaumont. With him were Lord Clancarty, Lord Stewart and Lord Cathcart. He had a small but capable staff including Edward Cooke, under-secretary of State for foreign affairs. When Castlereagh had to return to his parliamentary duties the duke of Wellington replaced him and Lord Clancarty was principal representative after the duke's departure. The restored Louis XVIII. sent the astute diplomatist, Prince Talleyrand, who had only mediocre helpers except La Besnardière, one of Napoleon's permanent officials. Spain, Portugal and Sweden also had only men of moderate parts to represent them, in Labrador, Palmella and Lövenheilm. Count Münster, who represented the British Prince Regent as ruler of Hanover, had much influence on German questions. Many of the rulers of the minor States of Europe put in an appearance. With them came a host of courtiers, secretaries and ladies to enjoy the magnificent hospitality of the almost bankrupt Austrian court. The social side of the congress made a great impression on the age, and on history. It was one of the causes of the long and unexpected delay in producing a result, for Metternich at least sometimes subordinated business to pleasure.

Procedure of the Congress.—This was due to the difficulty and complexity of the problems to be solved. First there was the problem of the organization of the congress, for which there was no precedent. The "four" were determined to keep the management of the main problems entirely in their own hands; but since they had rather rashly summoned a congress they must pay some attention to it. The ministers of the "four" assembled early to discuss this problem, and finally agreed on Sept. 22 that the "four" should have the "initiative," by which they meant the "decision" of the future of all the conquered territories. They were then to "communicate" with France and Spain. The "congress" was to be summoned only when all was ready.

This was the situation which Talleyrand found when he arrived on Sept. 24. He refused to accept it and was supported by Labrador. He denied that either the "four" or the "six" were legally constituted bodies, and desired that the congress should be summoned to elect a directing committee. If there was any other body which had any rights it was the "eight" Powers who had signed the Paris treaties. The "four" were much disturbed, for they knew that all the smaller Powers would support Talleyrand if they gave him the chance of appealing to them. But they had no intention of giving way, and refused to summon a meeting of all the plenipotentiaries. A notice was issued that the opening of the congress was postponed till Nov. 1. No solution could be found, however, and after a meeting of the "eight" on Oct. 30 the opening was again postponed.

Meanwhile the work of the congress proceeded without the sanction of the main body of plenipotentiaries. The "four" discussed the main territorial problems informally amongst themselves. The "eight" assumed the formal direction of the congress; a committee of German states met to draw up a constitution for Germany, and a special committee on Switzerland was appointed by the "four." Talleyrand was thus excluded from the main work of the congress, but his protests on behalf of the smaller Powers grew fainter as he realised that the "four" were not in agreement, Castlereagh and Metternich gradually won his confidence and at last insisted on France being admitted to the "four." The "four" thus became the "five" and it was this committee of five which was the real Congress of Vienna. Between Jan. 7 and Feb. 13 it settled the frontiers of all territories north of the Alps and laid the foundations for the settlement of Italy. In this it was much assisted by a statistical committee which Castlereagh had proposed. Meanwhile the committee of "eight" dealt with more general matters. The congress as a representative body of all Europe never met.

Poland and Saxony.—The great difficulty which nearly produced war was the disposition of Poland and Saxony. By treaties signed in 1813 Alexander had promised that the sovereigns of Prussia and Austria should rule over as many subjects as they had done before they were reduced in size by Napoleon. He had also promised that the duchy of Warsaw, which Napoleon had constituted out of the Prussian and Austrian shares of the Polish partitions, should be divided between the three Powers. After the battle of Leipzig, however, he claimed practically all Poland for Russia, and suggested that Austria could find compensation in Italy, and Prussia by annexing all Saxony, whose king had been the most faithful of Napoleon's vassals. In this plan he was moved by a sincere wish to give the Poles an opportunity for the expression of their nationality; but, of course, he intended to keep Russian sovereignty over all Poland. Metternich was much alarmed, and Hardenberg, while very desirous of Saxony, was not anxious to see Russia's frontier extended so far. Castlereagh was also, as a true disciple of Pitt, afraid of Russian expansion. Accordingly Castlereagh encouraged Austria to agree to the sacrifice of Saxony to Prussia so that the three Powers could oppose Russia's demands on Poland. With great difficulty he eventually succeeded in so doing, carrying on himself meanwhile an exceedingly frank controversy with Alexander. But the plan, which included an offer of constituting an entirely independent Poland, which it was known Alexander must reject, failed because Frederick William III., who was grateful to the tsar for his help in the overthrow of Napoleon, refused to support Hardenberg when the crisis came. Metternich and Hardenberg were, therefore, estranged, and the former withdrew his consent to Prussia's absorption of all Saxony. Prussia then went altogether on to Russia's side, and a complete deadlock resulted.

Castlereagh's Diplomacy.—Castlereagh had been much chagrined at the failure of his first plan. Moreover, his cabinet were alarmed at his activity in European matters, and he was warned against going too far. The difficult negotiations with the United States, with whom Britain was still at war, also made caution necessary. Nevertheless, Castlereagh saw that if a European war broke out both France and Britain would certainly be involved

before it was over. He had already prepared the way with Talleyrand, and in December both he and Metternich promised Talleyrand that the Bourbon house should be re-established in Naples instead of Murat. Secure of Talleyrand's support they insisted that France should be admitted to the committee of the "four." When Hardenberg threatened war, Castlereagh drew up a secret treaty of defensive alliance which Talleyrand and Metternich signed on Jan. 3, 1815. For a few days the issue was doubtful, but the tsar, who had already obtained most of Russia's demands, *inclined to peace, and eventually Prussia gave way.* With Castlereagh *acting as mediator*, a compromise was arranged on the question of Saxony, and then the rest of the territorial settlement was comparatively easy, especially as Castlereagh reduced the demands of both Hanover and the Netherlands, whose policy was ultimately controlled by Britain.

Decisions of the Congress.—Alexander gave back Galicia to Austria, Thorn and a region round it to Prussia, while Cracow was made a free town. The rest of the duchy of Warsaw was incorporated as a separate kingdom under the tsar's sovereignty. Prussia got two-fifths of Saxony, and was compensated by extensive additions in Westphalia and on the left bank of the Rhine. It was Castlereagh who insisted on her accepting this latter territory, with which it was suggested the king of Saxony should be compensated, for he wanted Prussia to guard the Rhine against France and act as a buttress to the new kingdom of the Netherlands, which Holland had formed by incorporating Belgium. Austria was compensated by Lombardy and Venice. She also got back most of the Tyrol. The South German States on the whole did well. Hanover was also enlarged. The outline of a constitution, a loose confederation, was drawn up for Germany. It was a triumph for Metternich and a defeat for Stein. Denmark lost Norway to Sweden but got Lauenberg, while Swedish Pomerania went to Prussia. In Italy, Piedmont absorbed Genoa; Tuscany and Modena went to an Austrian archduke; Parma was given to Marie Louise, though the young Napoleon's claims to succeed failed to win British and French approval. The papal territory was restored to the pope. Murat's fate was decided even before his rash attempt after Napoleon's return from Elba, and the Sicilian Bourbons restored to Naples. Switzerland was given a new constitution. Valuable articles were included on the free navigation of international rivers and diplomatic precedence. (*See* DIPLOMACY.) Castlereagh's great efforts on behalf of the abolition of the slave trade were only rewarded by a pious declaration.

The final act, which included all these agreements in one great instrument, signed on June 9, 1815, by the "eight" (except Spain, who refused as a protest against the Italian settlement) was afterwards acceded to by all the other Powers, and was the most comprehensive treaty which Europe had ever possessed.

As a result the lines laid down by the Congress of Vienna lasted, except for one or two changes, for over 40 years. The statesmen had successfully worked out their principle of a balance of power. But the idea of nationality had been almost entirely ignored—necessarily so because it was not yet ready for expression. Territories had been bartered about without much reference to the wishes of their inhabitants. Until an even greater settlement took place it was customary for historians to condemn the statesmen of Vienna. It is now realised how difficult their task was, and the fact that they secured for Europe a period of peace, which was its cardinal need, is fully recognized. But the statesmen failed to give to international relations any organ by which their work could be adapted to the new forces of the 19th century, and it was ultimately doomed to destruction.

(C. K. W.)

VIENNE, a department of west-central France, formed in 1790 out of Poitou (four-fifths of its present area), Touraine (one-seventh) and Berry, and bounded by Deux-Sèvres on the west, Charente on the south, Haute-Vienne on the south-east, Indre on the east, Indre-et-Loire on the north-east and north and Maine-et-Loire on the north-west. Pop. (1926), 310,474. Area, 2,711 sq.m. The department includes the basin of the Vienne from the point at which it emerges from the Plateau Central down to its junction with the Greuse, while its extreme south-west corner includes a small part of the course of the Charente. It thus contains the famous gate of Poitou (Seuil du Poitou) between the Plateau Central and the Gâtine, the historic south-west entry into the Paris basin. The winter average temperature is 39° to 41° F, the summer average temperature being 66° to 68°. The prevailing winds are from the south-west and west. The annual rainfall is 24 in. in the north to 32 in. in the south.

Wheat, oats and barley are the principal cereals grown, other important crops being lucerne, sainfoin, clover, mangel-wurzels and potatoes. Some colza and hemp are grown. The district of Poitiers grows good red wine, and the white wine of Trois-Moutiers near Loudun is well known. The breeding of live stock is fairly active. Poitou is famous for its mules, and the geese and turkeys of the department are highly esteemed. Among the fruit trees are the chestnut, walnut and almond. In the forests a small number of wild boars and other wild game survives. Freestone is quarried. There are mineral springs at La Roche-Posay. The most important industrial establishments are the national arms manufactory at Châtellerault and the cutlery works near that town. The capital of Vienne is Poitiers, and the department is divided into 3 arrondissements (Poitiers, Châtellerault, Montmorillon), 31 cantons and 300 communes. The chief towns are Poitiers, Châtellerault, Loudun, Montmorillon and Chauvigny (*qq.v.*). Sanxay has ruins of a theatre and other Gallo-Roman remains near by. Vienne is rich in megalithic monuments.

VIENNE, the chief town of an arrondissement of the department of the Isère, France. Pop. (1926) 21,861. Vienne stands on the left bank of the Rhone just below the junction of the Gère with the Rhone, between the river and low hills, and about 20 m. by rail S. of Lyons. Its site is an immense mass of ancient *débris*, which is constantly yielding interesting antiquities. On the bank of the Gère are traces of the ramparts of the old Roman city, and on the Mont Pipet (E. of the town) are the remains of an amphitheatre, while the ruined castle there was built in the 13th century on Roman substructures. Several of the ancient aqueducts (one only is now actually in use) are still to be seen.

Vienne, originally the capital of the Allobroges, became a Roman colony about 47 B.C. under Caesar, who embellished and fortified it. A little later these colonists were expelled by the Allobroges; the exiles then founded the colony of Lyons (Lugdunum). It was not till the days of Augustus and Tiberius that Vienne regained all its former privileges as a Roman colony. Later it became the capital of the Provincia Viennensis. In 257 Postumus was proclaimed emperor here, and for a few years Vienne was the capital of a short-lived provincial empire. It is said to have been converted to Christianity by Crescens, the disciple of St. Paul. There were Christians here in 177, as in the Greek letter (preserved to us by Eusebius) addressed at that date by the churches of Vienne and Lyons to those of Asia and Phrygia mention is made of "the" deacon of Vienne. The first bishop certainly known is Verus, who was present at the Council of Arles in 314.

About 450 Vienne became an archbishopric and continued one till 1790, when the see was suppressed. The archbishops disputed with those of Lyons the title of "Primate of All the Gauls." Vienne was conquered by the Burgundians in 438, and in 534 was taken by the Franks. Sacked in 558 by the Lombards and in

737 by the Saracens, the government of the district was given by Charles the Bald in 869 to a Count Boso, who in 879 was proclaimed king of Provence, and was buried in 887 in the cathedral church of St. Maurice. Vienne then continued to form part of the kingdom of Provence or Arles till in 1032 it reverted to the Holy Roman Empire. Vienne was sacked in 1562 by the Protestants under the baron des Adrets, and was held for the Ligue 1590–95, when it was taken by Montmorency. The fortifications were demolished between 1589 and 1636. In 1790 the archbishopric was abolished, the title "Primate of all the Gauls" being attributed to the archbishops of Lyons.

Ancient Monuments.—The town possesses two fine Roman monuments. One is the temple of Augusta and Livia, a building of the Corinthian order, built by the emperor Claudius, and inferior only to the Maison Carrée at Nîmes. From the 5th century to 1793 it was a church (Notre Dame de Vie), and the "festival of reason" was celebrated in it at the time of the Revolution. The other is the *Plan de l'Aiguille*, a truncated quadrangular pyramid, about 52 ft. in height, resting on a portico with four arches; it is now generally believed to have been part of the *spina* of a large circus, the outlines of which have been traced. The church of St. Peter belonged to an ancient Benedictine abbey and was rebuilt in the 9th century, in the earliest Romanesque style. It has of late years been completely restored, and shelters the magnificent *Musée Lapidaire*. The former cathedral church of St. Maurice (11th to 16th centuries), has three aisles, but no apse or transepts. The most striking portion is the W. front (1533), which rises from a terrace overhanging the Rhone.

There are very important cloth factories and also distilleries, iron foundries, refining furnaces, etc. Vienne is the seat of a sub-prefect, of a tribunal of commerce, a chamber of commerce and a board of trade-arbitrators.

VIENNE, a river of central France, 219 m. long, a left-hand tributary of the Loire. Rising on the plateau of Millevaches at a height of 2,789 ft., the Vienne flows westward through the hilly country of the crystalline rocks of the Central Plateau of France. The first large town on its banks is Limoges, below its confluence with the Taurion (right). The river next reaches St. Junien, turns abruptly northwards to Confolens and passes on to the Jurassic rocks to flow through a picturesque and wider valley. Passing Chauvigny, it proceeds to the confluence of the Clain (left), on which stands Poitiers, just above Châtellerault. Below that town it receives the Creuse (right), which rises on the Millevaches Plateau and is 159 m. long. From near Châtellerault, past Chinon, to its junction with the Loire the Vienne flows across Cretaceous strata. There is little river-traffic on the Vienne below its confluence with the Creuse (30 m.). (*See* LOIRE.)

VIENNE, COUNCIL OF, an ecclesiastical council, which in the Roman Catholic Church ranks as the fifteenth ecumenical synod. It met from October 16, 1311, to May 6, 1312, under the presidency of Pope Clement V. The transference of the Curia from Rome to Avignon (1309) had brought the papacy under the influence of the French crown; and this position Philip the Fair of France now endeavoured to utilize by demanding from the pope the dissolution of the powerful and wealthy order of the Temple, together with the introduction of a trial for heresy against the late Pope Boniface VIII. To evade the second claim, Clement gave way on the first (*see* TEMPLARS). On the 22nd of March the order of the Temple was suppressed by the bull *Vox clamantis*, while further decisions as to the treatment of the order and its possessions followed later. Additional decisions were necessitated by the violent disputes which raged within the Franciscan order as to the observance of the rules of St. Francis of Assisi.

See Mansi, *Collectio Conciliorum*, vol. xxv.; Hefele, *Conciliengeschichte*, vol. vi. pp. 532–534.

VIERSEN, a town in the Prussian Rhine province, 11 m. by rail S.W. from Crefeld, and at the junction of lines to München-Gladbach, Venlo, etc. Pop. (1925) 32,037. Viersen is one of the chief seats in the lower Rhine country for the manufacture of velvets, silks and plush, cotton, paper, boots and cement.

VIERZON, a town of central France, in the department of Cher, 20 m. N.W. of Bourges by rail. The Cher and the Yèvre unite at the foot of the hill on which lie Vierzon-Ville (pop. [1926] 11,313) and Vierzon-Villages (pop. [1926] 6,929); Vierzon-Bourgneuf (pop. [1926] 2,114) is on the left bank of the Cher. The town has a port on the canal of Berry and is an important junction on the Orléans railway; there are several large manufactories for the production of agricultural machines, also foundries, porcelain, brick and tile works and glass works.

VIETA (or VIÈTE), **FRANÇOIS,** SEIGNEUR DE LA BIGOTIÈRE (1540–1603), more generally known as FRANCISCUS VIETA, French mathematician, was born at Fontenay-le-Comte, in Poitou. According to F. Ritter, *Bolletino Boncompagni* (1868), Vieta was brought up as a Catholic, and died in the same creed; but there can be no doubt that he belonged to the Huguenots for several years. On the completion of his studies in law at Poitiers Vieta became an advocate in his native town, and later councillor of the parlement of Brittany. Rohan, the well-known chief of the Huguenots, took Vieta under his special protection. After the accession of Henry IV., Vieta became in 1589 councillor of the parlement at Tours, and subsequently a royal privy councillor.

We know of one important service rendered by Vieta as a royal officer. While at Tours he discovered the key to a Spanish cipher, consisting of more than 500 characters, and thenceforward all the despatches in that language which fell into the hands of the French could be easily read. Philip II. was so convinced that his cipher was a safe one that when he found the French were aware of the contents of his letters he complained to the pope that the French were using sorcery against him.

Vieta printed at his own expense the numerous papers which he wrote on various branches of this science, and communicated them to scholars in almost every country of Europe.

Vieta has been called the father of modern algebra. All that is wanting in his writings, especially in his *Isagoge in artem analyticam* (1591), in order to make them look like a modern school algebra, is merely the sign of equality. His *Recensio canonica effectionum geometricarum* is what we now call an algebraic geometry.

He conceived methods for the general resolution of equations of the second, third and fourth degrees different from those of Ferro and Ferrari, with which, however, it is difficult to believe him to have been unacquainted. He knew the connection existing between the positive roots of an equation (which, in his day, were alone thought of as roots) and the coefficients of the different powers of the unknown quantity. He found out the formula for deriving the sine of a multiple angle, knowing that of the simple angle with due regard to the periodicity of sines. This formula must have been known to Vieta in 1593. In his *Apollonius Gallus* (1600) Vieta made use of the centre of similitude of two circles. Lastly he gave an infinite product for the number π. (*See* article on CIRCLE.)

Vieta's collected works were issued under the title of *Opera Mathematica* by F. van Schooten at Leyden in 1646.

VIGAN, a municipality (with administration centre and 25 *barrios* or districts) and the capital of the province of Ilocos Sur, Luzon, Philippine islands, near the mouth of the Abra river, about 200 m. N. by W. of Manila. Pop. (1918) 17,765. In 1918, Vigan had 38 factories and 45 household industry establishments, with outputs valued at 255,200 and 93,000 pesos respectively. The language is Ilocano.

VIGÉE-LEBRUN, MARIE-ANNE ELISABETH (1755–1842), French painter, was born in Paris on Apr. 16, 1755, the daughter of a painter, from whom she received her first instruction, though she benefited more by the advice of Doyen, Greuze, Joseph Vernet and others. When only about 20 years of age she had made her name by her portraits of Count Orloff and the duchess of Orleans, and had become a general favourite in society. In 1776 she married the painter and art-critic J. B. P. Lebrun, and in 1783 her picture of "Peace bringing back Abundance" (now at the Louvre) gained her the membership of the Academy. When the Revolution broke out in 1789 she escaped first to Italy, where she worked at Rome and Naples. At Rome she painted the Princesses Adelaide and Victoria, and at Naples the "Lady Hamilton as a Bacchante" now in the collection of

Tankerville Chamberlayne. She then visited Vienna, Berlin and St. Petersburg, returning to Paris in 1781. In 1782 she went to London, where she painted Lord Byron and the prince of Wales. She was a great traveller, and her portraits are to be found in the collections of many countries. She died in Paris on Mar. 30, 1842 at the age of 87, having been widowed for 29 years.

Among her many sitters was Marie Antoinette, of whom she painted over 20 portraits between 1779 and 1789. A portrait of the artist is in the hall of the painters at the Uffizi, and another at the National Gallery. The Louvre owns two portraits of Mme. Lebrun and her daughter, besides five other portraits.

A full account of her eventful life is given in her *Souvenirs* (1835, 1837) and in C. Pillet's *Mme. Vigée-Le Brun* (1890). The artist's autobiography has been translated by Lionel Strachey, *Memoirs of Mme. Vigée-Lebrun* (New York, 1903), fully illustrated.

VIGELAND, ADOLF GUSTAV (1869–), Norwegian sculptor, was born at Mandel in South Norway on April 11, 1869. In early youth he studied wood engraving and in 1889 at Christiania (Oslo), produced his first work as a sculptor, a relief depicting incidents from the *Iliad*. He afterwards travelled and studied under Skeibrok in Christiania and Bissen in Copenhagen. Vigeland's work deals with the primitive emotion of men. He forsook his earlier semi-impressionistic form of art and adopted a more classic style. His chief work "The Fountain," begun in 1915, is still unfinished (1926). It was intended, when complete, to consist of 26 large groups of stone and a multitude of minor figures in bronze; the whole depicting the history of mankind, from barbarism to civilisation. Vigeland also achieved a wide reputation as a portrait sculptor.

See M. G. Vidalene, *L'art norvégien contemporain* (1921).

VIGEVANO, a town and episcopal see of Lombardy, Italy, in the province of Pavia, on the right bank of the Ticino, 24 m. by rail S.W. from Milan on the line to Mortara, 381 ft. above sea-level. Pop. (1921) 20,920 (town); 30,583 (commune). It is a mediaeval walled town, with an arcaded market-place and a castle of the Sforza family, dating from the 14th century and adorned with a loggia by Bramante and a tower imitating that of Filarete in the Castello Sforzesco at Milan. It is a place of some importance in the silk trade.

VÍGFÚSSON, GÚDBRANDR (1828–1889), the foremost Scandinavian scholar of the 19th century, was born of a good Icelandic family in Breiðafjord. In 1849 he came to Copenhagen university as a *bursarius* in the Regense college. He was, after his student course, appointed *stipendiarius* by the Arna-Magnaean trustees, and worked for 14 years in the Arna-Magnaean library till, as he said, he knew every scrap of old vellum and of Icelandic written paper in that whole collection. During his Danish life he twice revisited Iceland (last in 1858), and made short tours in Norway and south Germany with friends. In 1866, after some months in London, he settled down in Oxford, which he made his home for the rest of his life. He held the office of reader in Scandinavian at the University of Oxford (a post created for him) from 1884 till his death. He was a jubilee doctor of Upsala, 1877, and received the Danish order of the Dannebrog in 1885. Vígfússon died of cancer and was buried in St. Sepulchre's cemetery, Oxford. His memory was remarkable; if the whole of the Eddic poems had been lost he could have written them down from memory.

By his *Túnatál* (written between Oct. 1854 and April 1855) he laid the foundations for the chronology of Icelandic history, in a series of conclusions that have not been displaced (save by his own additions and corrections), and that justly earned the praise of Jacob Grimm. His editions of Icelandic classics (1858–68), *Biskopa Sögur, Bardar Saga, Forn Sögur* (with Möbius), *Eyrbyggia Saga* and *Flateyar-bók* (with Unger) opened a new era of Icelandic scholarship, and can only fitly be compared to the Rolls Series editions of chronicles by Dr. Stubbs for the interest and value of their prefaces and texts. Seven years of constant and severe toil (1866–73) were given to the Oxford Icelandic-English dictionary, incomparably the best guide to classic Icelandic, and a monumental example of single-handed work. His later series of editions (1874–85) included *Orkneyinga* and *Hâconar Saga*, the great and complex mass of Icelandic historical *sagas*, known as *Sturlunga* and the *Corpus Poeticum Boreale*, in which he edited the whole body of classic Scandinavian poetry.

VIGIL, in the Christian Church, the eve of a festival. The *vigiliae* (*pernoctationes*, *παννυχίδες*) were originally the services celebrated during the night preceding the feast. The abuses connected with nocturnal vigils led to their being attacked, especially by Vigilantius of Barcelona (*c.* 400), against whom Jerome fulminated in this as in other matters. The custom, however, persisted until the middle ages, when the nocturnal *vigiliae* were, except in the monasteries, gradually discontinued, the vigil services, with the term itself, being transferred to the day preceding the feast. The only surviving relic of the older custom, in the Roman Catholic Church, is the midnight mass at Christmas.

The Church of England has a special collect, gospel and epistle for "Easter Even" only. For the other vigils recognized, the rubric directs that the collect appointed for the feast "shall be said at the Evening Service next before."

VIGILANCE COMMITTEE, in the United States, a self-constituted judicial body, occasionally organized in the western frontier districts for the protection of life and property. The first committee of prominence bearing the name was organized in San Francisco in June 1851, when the crimes of desperadoes who had immigrated to the gold-fields were rapidly increasing in number and it was said that there were venal judges, packed juries and false witnesses. At first this committee was composed of about 200 members; afterwards it was much larger. The general committee was governed by an executive committee and the city was policed by sub-committees. Within about 30 days four desperadoes were arrested, tried by the executive committee and hanged, and about 30 others were banished. Satisfied with the results, the committee then quietly adjourned, but it was revived five years later. Similar committees were common in other parts of California and in the mining districts of Idaho and Montana. That in Montana exterminated in 1863–64 a band of outlaws organized under Henry Plummer, the sheriff of Montana City; 24 of the outlaws were hanged within a few months. Committees or societies of somewhat the same nature were formed in the Southern States during the Reconstruction period (1865–72) to protect white families from negroes and "carpet-baggers," and besides these there were the Ku-Klux-Klan (*q.v.*) and its branches, the Knights of the White Camelia, the Pale Faces and the Invisible Empire of the South, the principal object of which was to control the negroes by striking them with terror.

See T. J. Dimsdale, *The Vigilantes of Montana* (Virginia City, 1866); H. H. Bancroft, *Popular Tribunals* (San Francisco, 1887); P. Garnett, ed., *Papers of the San Francisco Committee of Vigilance of 1851* (Berkeley, Calif., 1910–19); Mary Floyd Williams, ed., *Papers of the San Francisco Committee of Vigilance of 1851* (Berkeley, 1919); Mary Floyd Williams, *History of the San Francisco Committee of Vigilance of 1851* (Berkeley, 1921); and William John McConnell, *Frontier Law* (Yonkers-on-Hudson, N.Y., 1924).

VIGILANTIUS (*fl. c.* 400), the presbyter, celebrated as the author of a work, no longer extant, against superstitious practices, which called forth one of the most violent and scurrilous of Jerome's polemical treatises, was born about 370 at Calagurris (Cazères or perhaps Saint Bertrand de Comminges, Haute-Garonne), where his father kept a "statio" or inn on the great Roman road from Aquitania to Spain. Sulpicius Severus sent him in 395 with letters to Paulinus of Nola. On his return to Severus in Gaul he was ordained, and set out for Palestine, where he was received by Jerome at Bethlehem. Vigilantius was dragged into the dispute then raging about Origen, in which he did not see eye to eye with Jerome. About 403, some years after his return from the East, Vigilantius wrote his work against superstitious practices, in which he argued against relic worship, as also against the vigils in the basilicas of the martyrs, the rejection of earthly goods and the attribution of special virtue to the unmarried state, especially in the case of the clergy. All that is known of the work is through Jerome's treatise *Contra Vigilantium*, or, as that controversialist would seem to prefer saying, "Contra Dormitantium." The influence of Vigilantius long remained potent both in France and Spain, as is proved by the polemical tract of

Faustus of Rhegium (d. *c.* 490).

VIGILIUS, pope from 537 to 555, succeeded Silverius and was followed by Pelagius I. He was ordained by order of Belisarius while Silverius was still alive; his elevation was due to Theodora, who had induced him to promise to disallow the council of Chalcedon, in connection with the "three chapters" controversy. But he failed to fulfil his promise, and was summoned to Constantinople, which he reached in 547. There he issued a document known as his *Judicatum* (548), in which he condemned indeed the three chapters, but expressly disavowed any intentions thereby to disparage the council of Chalcedon. After some trimming, he prepared another document, the *Constitutum ad Imperatorem,* which was laid before the so-called fifth "oecumenical" council in 553, and led to his condemnation by the majority of that body, some say even to his banishment. Ultimately, however, he was induced to confirm the decrees of the council, and was allowed after an enforced absence of seven years to set out for Rome. He died at Syracuse, before he reached his destination, on June 7, 555.

VIGINTISEXVIRI. This was the collective name which was given in Rome to "26" magistrates of inferior rank. They were divided into six boards, two of which were abolished by Augustus. Their number was thereby reduced to twenty and their name altered to VIGINTIVIRI ("the twenty"). The six boards were: (1) *Tresviri capitales* (*see* TRESVIRI); (2) *Tresviri monetales;* (3) *Quatuorviri viis in urbe purgandis,* who had the care of the streets and roads inside the city; (4) *Duoviri viis extra urbem purgandis* (*see* DUUMVIRI), abolished by Augustus; (5) *Decemviri stlitibus iudicandis* (*see* DECEMVIRI); (6) *Quatuor praefecti Capuam Cumas,* abolished by Augustus.

See Mommsen, *Römisches Staatsrecht,* ii. (1887), p. 592.

VIGLIUS, the name taken by WIGLE VAN AYTTA VAN ZUICHEM (1507–1577), Dutch statesman and jurist, a Frisian by birth, who was born on Oct. 19, 1507. He studied at various universities—Louvain, Dôle and Bourges among others—devoting himself mainly to the study of jurisprudence, and afterwards visited many of the principal seats of learning in Europe. His great abilities attracted the notice of Erasmus and other celebrated men, and his renown was soon wide and general. Having lectured on law at the universities of Bourges and Padua, he accepted a judicial position under the bishop of Münster which he resigned in 1535 to become assessor of the imperial court of justice (*Reichskammergericht*). For five years he was professor at Ingolstadt. In 1542 the official connection of Viglius with the Netherlands began. At the emperor's invitation he became a member of the council of Mechlin, and some years later president of that body. He was soon one of the most trusted of the ministers of Charles V., whom he accompanied during the war of the league of Schmalkalden in 1546. He was generally regarded as the author of the edict against toleration issued in 1550; a charge which he denied. When the emperor abdicated in 1555 Viglius was anxious to retire also, but at the instance of King Philip II. he remained at his post and was rewarded by being made coadjutor abbot of St. Bavon, and in other ways. In 1559, when Margaret, duchess of Parma, became regent of the Netherlands, Viglius was an important member of the small circle who assisted her in the work of government. He was president of the privy council, member, and subsequently president, of the state council, and a member of the committee of the state council called the *consulta.* In 1565 he was allowed to give up the presidency of the state council, but was persuaded to retain his other posts. However, he had lost favour with Margaret, who accused him to Philip of dishonesty and simony, while his orthodoxy was suspected. When the duke of Alva arrived in the Netherlands Viglius at first assisted him; but he subsequently opposed the duke's scheme of extortion. He died at Brussels on May 5, 1577.

He wrote a *Tagebuch des Schmalkaldischen Donaukriegs,* edited by A. von Druffel (Munich, 1877), and some of his lectures were published under the title *Commentarii in decem Institutionum titulos* (Lyons, 1564). His *Vita et opera historica* are given in the *Analecta Belgica* of C. P. Hoynck van Papendrecht (the Hague, 1743). *See* L. P. Gachard, *Correspondance de Philippe II. sur les affaires des Pays-Bas* (Brussels, 1848–79); and *Correspondance de Marguerite d'Autriche, duchesse de Parme, avec Philippe II.* (Brussels, 1867–81); and E. Poullet, *Correspondance de cardinal de Granvelle* (Brussels, 1877–81).

VIGNE, PAUL DE (1843–1901), Belgian sculptor, was born at Ghent. His first exhibit was the "Fra Angelico da Fiesole" at the Ghent Salon in 1868. In 1872 he exhibited at the Brussels Salon. He was employed by the government to execute caryatides for the Brussels conservatoire. In 1876 the Antwerp Salon accepted his busts of E. Hiel and W. Wilson, which were afterwards placed in the communal museum at Brussels. Until 1882 he lived in Paris, where he produced the marble statue "Immortality" (Brussels Gallery), and "The Crowning of Art," a bronze group on the façade of the Palais des Beaux-Arts at Brussels. His monument to the popular heroes, Jean Breydel and Pierre de Coninck, was unveiled at Bruges in 1887. At his death he left unfinished his principal work, the Anspach monument, which was erected at Brussels under the direction of the architect Janlet with the co-operation of various sculptors.

Other works are the bronze bust of "Psyche" (Brussels Gallery), of which there is an ivory replica; the marble statue of Marnix de Ste. Aldegonde in the Square du Sablon, Brussels; the Metdepenningen monument in the cemetery at Ghent; and the monument to Canon de Haerne at Courtrai.

See E. L. de Taeye, *Les Artistes Belges contemporains* (Brussels, 1896), and O. G. Destrée, *The Renaissance of Sculpture in Belgium* (London, 1895).

VIGNETTE, in architecture, a running ornament, representing a little vine, with branches, leaves and grapes, common in the Tudor period. It is also called *trayle.* From the transference of the term to book-illustration resulted the sense of a small picture, vanishing gradually at the edge.

VIGNY, ALFRED DE (1797–1863), French poet, was born at Loches (Indre-et-Loire) on March 27, 1797. For generations the ancestors of Alfred de Vigny had been soldiers, and he himself joined the army, with a commission in the Household Troops, at the age of sixteen. But the Revolutionary and Napoleonic wars were over, and after twelve years of life in barracks he retired. While still serving he had made his mark, if as yet unrecognized, by the publication in 1822 of a volume of poems, and in 1826 by another, together with the famous prose romance of *Cinq-Mars,* which derived some of its popularity from the enormous vogue of the novels of Scott. Some of his most celebrated pieces—*Eloa, Dolorida, Moïse*—appeared (1822–23) before the work of younger members of the Romantic school whose productions strongly resemble these poems. Nor is this originality limited to the point which he himself claimed in the Preface to his collected *Poems* in 1837—that they were "the first of their kind in France, in which philosophic thought is clothed in epic or dramatic form." Indeed this claim is disputable in itself; it is in *poetic,* not *philosophic* quality, that his idiosyncrasy and precursorship are most remarkable. It is quite certain that the other Alfred—Alfred de Musset—felt the influence of his elder namesake, and the verses of Hugo, and even of Lamartine, considerably his elder, owe something to him. His poetry, written for the most part in the earlier part of his life, is small in volume, but it forms probably his chief title to fame.

Alfred de Vigny, though he belonged to no *cénacle,* but shut himself up, as the saying went, in a *tour d'ivoire,* belonged to the Romantic movement of the 'thirties, and was stimulated by it to drama and to novel-writing. In the year before the revolution of July he produced at the Théâtre Français a translation, or rather paraphrase, of *Othello,* and an original piece, *La Maréchale d'Ancre.* In 1832 he published the curious book *Stello,* containing studies of unlucky youthful poets—Gilbert, Chatterton, Chénier—and in 1835 he brought out his drama of *Chatterton,* which, by the hero's suicide, shocked French taste even after five years of Romantic education, but had a considerable success. The same year saw the publication of *Servitude et grandeur militaires,* a collection of sketches rather than a connected work in which Vigny's military experience, his idea of the soldier's duties, and his rather poetical views of history were all worked in. The subjects of *Chatterton* and *Othello,* were, of course drawn from

English sources, and in fact Alfred de Vigny knew English well, lived in England for some time and married in 1828 an Englishwoman, Lydia Bunbury.

In 1845 Alfred de Vigny was elected to the Academy, but made no compromise in his "discourse of reception," which was unflinchingly Romantic. Still, he produced nothing save a few scraps; and, beyond the work already enumerated, little has to be added except his *Journal d'un poète* and the poems called *Les Destinées*. Vigny died at Paris on Sept. 17, 1863.

See M. Paléologue, "Alfred de Vigny" in the *Grands écrivains français* (1891); L. Dorison, *Alfred de Vigny, poète-philosophe* (1892) and *Un symbole social* (1894); G. Asse's *Alfred de Vigny et les éditions originales de sa poésie* (1895); E. Dupuy's *La Jeunesse des Romantiques* (1905); E. Lauvrière's *Alfred de Vigny* (Paris, 1910); L. Séché, *Alfred de Vigny* (2 vols., 1916); Anatole France, *Alfred de Vigny* (1923); M. Citoleux, *A. de Vigny, Persistances classiques et affinités étrangères* (1924); A. V. de Vigny, *Lettres inédites à Victor Hugo, 1820–1831* (1925). There are many editions of Vigny's works; there is a critical edition (1914) of his poems, edited by E. Estève for the Soc. des Textes français modernes.

VIGO, a seaport and naval station of north-western Spain, in the province of Pontevedra; on Vigo bay (Ria de Vigo) and on a branch of the railway from Tuy to Corunna. Pop. (1920) 53,100. Vigo was attacked by Sir Francis Drake in 1585 and 1589. In 1702 a combined British and Dutch fleet under Sir George Rooke and the duke of Ormonde destroyed a Franco-Spanish fleet in the bay, and captured treasure to the value of about £1,000,000. In 1719 Vigo was captured by the British under Viscount Cobham. Vigo bay, one of the finest of the Galician fjords, extends inland for 19 m., and is sheltered by low mountains and by the islands (Islas de Cies, ancient *Insulae Siccae*) at its mouth. The town is built on the south-eastern shore, and occupies a hilly site dominated by two obsolete forts. Vigo owes its importance to its deep and spacious harbour, and to its fisheries. It has developed very rapidly in the 20th century, and has more than doubled its population. It is a port of call for many lines trading between Western Europe and South America. The town contains flour, paper and sawmills, sugar and petroleum refineries, tanneries, distilleries and soap works.

VIIPURI, formerly Viborg, a seaport and summer resort of Finland in 60° 43′ N., 28° 45′ E., at the mouth of the Saima canal on the Bay of Viipuri in the Gulf of Finland. Pop. (1925) 48,367. The canal links it with a series of lakes. Its exports are cement and farm produce, and its imports coal, fertilizers, foodstuffs and manufactured goods. It is picturesquely situated on glaciated, dome-shaped, granite hills surrounding the bay, which is guarded by the naval station of Björkö. Viipuri is a tourist centre for the Finnish lakes. Its castle, built in 1293 by Marshal Torkel Knutson, was the first centre for the spread of Christianity in Karelia.

VIJAYANAGAR (vē-jah-yahn'ą-gar) ("the city of victory"), an ancient Hindu kingdom and ruined city of southern India. The kingdom lasted from about 1336 to 1565, forming during all that period a bulwark against the Mohammedan invasion from the north. The great part of its history is obscure; but its power and wealth are attested by more than one European traveller, and also by the character of the existing ruins. At the beginning of the 14th century Mohammedan raiders had effectually destroyed every Hindu principality throughout southern India, but did not attempt to occupy the country permanently. In this state of desolation Hindu nationality rose again under two brothers, named Harihara and Bukka, of whom little more can be said than that they were Kanarese by race. Hence their kingdom was afterwards known as the Carnatic (*q.v.*). In 1565, on the downfall of the kingdom, the confederate sultans of Bijapur, Ahmednagar and Golconda, overwhelmed the Vijayanagar army in the plain of Talikota, and sacked the defenceless city. The city has ever since remained a wilderness of immense ruins, which are now conserved by the British Government.

See R. Sewell, *A Forgotten Empire* (1900); and B. S. Row, *History of Vijayanagar* (Madras, 1906).

VIKING. A word *wicing*, "warrior," corresponding to the O. Norse *vikingr* and the modern *viking*, was current in England at least a century before the earliest recorded Scandinavian descents upon the West. Its Scandinavian equivalent early acquired the more specialized sense of "sea-warrior," and the modern term "Viking age" is a convenient designation of the phase of Scandinavian history which produced the incessant raiding expeditions characteristic of the 9th and early 10th centuries. Most of our evidence as to the Vikings of this period is derived from the literature of the lands which they visited, and is therefore essentially hostile. To contemporary chroniclers they were utterly hateful, faithless, cruel and enemies of civilization and the arts of peaceful life. Their own side of the story is untold, for the men who created the great literature of western Scandinavia had no certain memory of events or personalities in the true Viking age. Their character can only be inferred from the scale upon which their raids were planned, the forms of society which arose in the different lands of their settlement, and the archaeological evidence which reveals something of their culture. Judged in this way they cease to appear as a mere blind force of destruction. It becomes clear that they possessed their own culture, though it was not the culture of the Christian West. Long before the end of the 9th century they had learned to penetrate all the greater water-ways of Europe. And the raids through which they gained this knowledge were only preliminary to wider voyages through which at last even the New World became known for a moment to men of Scandinavian birth.

The Viking Raids.—The Vikings began by more or less desultory raids, in the course of which they seized upon some island, which they generally used as an arsenal for attacks on the mainland. At first the raids were made in the summer, and the *first wintering* in any new scene of plunder meant settlement in the country, and some sort of division of territory. After that the northerners assimilated themselves more or less to the natives of the country. This course was followed in the history of the Viking attacks on Ireland, the earliest of their continuous series of attacks. Thus they began by seizing the island of Rechru (now Lambay) in Dublin bay (A.D. 795) and in 20 years were on the northern, western and southern coasts; by A.D. 825 they ventured raids to a considerable distance inland. In A.D. 832 came a large fleet under Turgesius (Thorgestr). The new invader extended his conquests till, in A.D. 842, one-half of Ireland (called Lethcuinn or Con's Half) had submitted; he established his wife, Ota, as a sort of *völva*, or priestess, in what had been one of Ireland's most famous literary monasteries, Clonmacnoise. Turgesius was killed soon after, in 845; and though in A.D. 853 Olaf the White was over-king of Ireland, the Vikings' power diminished. In the end, territory was—if by no formal treaty—ceded to their influence; and the (Irish) kingdoms of Dublin and Waterford were established on the island.

This sketch may be taken as the prototype of Viking invasion of any region of Western Christendom which was continuously attacked. Almost simultaneously with the attacks on Ireland came others, probably also from Norway, on the western coasts and islands of Scotland. Plunderings of Iona are mentioned in A.D. 802, 806, and in the course of a generation almost all the monastic communities in western Scotland had been destroyed. On the Continent there were three distinct regions of attack. The Danes early settled on the island of Walcheren, which had, in fact, been given by the emperor Louis the Pious to a fugitive Danish king, Harald by name, who sought the help of Louis and adopted Christianity. From the island the raids extended on either side: sometimes eastward as far as the Rhine, and so into Germany proper; at other times westward to the Somme, and thus into the territory of Charles the Bald, the future kingdom of France. Toward the end of the 9th century all Frisia between Walcheren and the German ocean seems to have been possessed by the invaders. The serious attacks of the pirates in any part of the empire distant from their own lands began about the middle of the century, when they first wintered in the Seine territory. Their first attack on Paris was in A.D. 845; in A.D. 885–887 a much more important but unsuccessful one took place, the invaders receiving an indemnity for raising the siege and leave to pass beyond Paris into Burgundy. The settlement of Danes under Rollo on the lower Seine, *i.e.*, in Normandy, belongs to the next century.

The third region is the mouth of the Loire, where the island *point d'appui* was Noirmoutier. The Northmen wintered there in A.D. 843. No region was more often ravaged than that of the lower Loire, so rich in abbeys—St. Martin of Tours, Marmoutiers, St. Benedict, etc. But the country ceded to the Vikings under Hasting at the Loire mouth was insignificant and not in permanent occupation.

Near the end of the 9th century, however, the plundering expeditions which emanated from these three sources became so incessant and so widespread that we can signalize no part of west France as free from them, and at the same time much mischief was wrought in the Rhine country and in Burgundy. Unfortunately, at this point our best authority ceases; and we cannot well explain the changes which brought about the Christianization of the Normans and their settlement in Normandy as vassals of the West Frankish kings.

For the Viking attacks in the British Isles, the course of events is clearer. In its general features it follows the normal course. The Vikings had begun to visit the English coast about the end of the 8th century, but their serious attacks do not begin till 838. Their first wintering was on the contiguous island of Thanet in A.D. 851. In 865 England was visited by a "great army," which overthrew the ancient kingdoms of Northumbria, Mercia and East Anglia. Wessex was saved only by Alfred's victory at Edington, after which Guthrum, the Danish leader, accepted baptism and settled with his men in East Anglia. But the forces defeated at Edington represented but half of the Viking army in England at the time. The other half had already settled in Northumbria, and the region between Humber and Welland.

The six territories which we have signalized—Ireland, Western Scotland, England, the three in West Francia which merge into each other by the end of the 9th century—do not comprise the whole field of Viking invasion. To the east they twice sailed up the Elbe (A.D. 851, 880) and burnt Hamburg. Southwards they plundered far up the Garonne, and in the north of Spain; and one fleet of them sailed round Spain, plundering, but attempting in vain to establish themselves in this Arab caliphate. They plundered on the opposite African coast, and at last got as far as the mouth of the Rhone, and thence to Luna in Italy.

In the third quarter of the 9th century two distinct tendencies appeared among the Vikings in the West. One section was ready to settle down and receive territory at the hands of the Christian rulers; the other section adhered to a life of adventure and of plunder. A large portion of the great army, unable to obtain settlement in England, sailed to the Continent and spread devastation far and wide. Under command of two Danish "kings," Godfred and Siegfried, they were first in the country of the Rhine-mouth or the Lower Scheldt; afterwards dividing their forces, some devastated far into Germany, others extended their ravages on every side in northern France down to the Loire. The whole of these vast countries, Northern Francia and part of Burgundy and the Rhineland, were as much at their mercy as England before the battle of Edington, or Ireland before the death of Turgesius. But in every country alike the wave of Viking conquest now began to recede. The settlement of Normandy was the only permanent outcome of the Viking age in France. In England, under Edward the Elder and Aethelflaed, Mercia recovered a great portion of what had been ceded to the Danes. In Ireland a great expulsion of the invaders took place in the beginning of the 10th century. In the following generations the kingdoms of Denmark and Sweden became consolidated, and the energy of the Norwegian peoples found vent in the settlement of Iceland.

Severe as were the raids in Europe, and great as was the suffering—on account of which a special prayer, *A furore Normannorum libera nos* was inserted in some of the litanies of the West—if the Vikings had been nothing more than pirates their place in history would be insignificant. But the Viking outbreak has to some extent the character of a national movement. While some were harrying in the West others were founding Garðaríki (Russia) in the East; others were pressing farther south till they reached the eastern empire in Constantinople, so that when Hasting and Björn had sailed to Luna in the Gulf of Genoa the northern folk had almost put a girdle round the Christian world. There is every evidence that they were not a mere lawless folk, but under suitable conditions, as in their 10th century colony of Jómborg, could develop an elaborate discipline and a strict code of honour. They were not entirely unlettered, for the use of runes dates back considerably earlier than the Viking age.

The Viking Ships.—In certain material possessions—those belonging to war and naval adventure—the Vikings were ahead of the Christian nations. There is certainly a historical connection between the ships which the tribes on the Baltic possessed in the days of Tacitus and the Viking ships, a fact which would lead us to believe that the art of shipbuilding had been better preserved there than elsewhere in northern Europe. Merchant vessels must, of course, have plied between England and France or Frisia. But it is certain that even Charlemagne possessed no adequate navy. Nor was any English king before Alfred stirred up to undertake the same task. The Viking ships had a character apart. They may have owed their origin to the Roman galleys; they did without doubt owe their sails to them. Their structure was adapted to short voyages in a sea not exposed to the most violent storms or dangerous tides. They were shallow, narrow in the beam, pointed at both ends, and so eminently suitable for manoeuvring (with oars) in creeks and bays. The Viking ship had but one large and heavy square sail, and when a naval battle was in progress it would depend for its manoeuvring on the rowers. In saga literature we read of craft (of "long ships") with 20 to 30 benches of rowers, which would mean 40 to 60 oars. It is not probable that the largest viking ships had more than ten oars a side. As these ships must often, against a contrary wind, have had to row both day and night, it seems reasonable to imagine the crew divided into three shifts which would give twice as many men available to fight on any occasion as to row. Thus a 20 oared vessel would carry 60 men. But some 40 men per ship seems, for this period, nearer the average. In 896, it is incidentally mentioned in one place that five vessels carried 200 Vikings, an average of 40 per ship. Elsewhere about the same time we read of 12,000 men carried in 250 ships, an average of 48.

The round and painted shields of the warriors hung outside along the bulwarks; the vessel was steered by an oar at the right side. Prow and stern rose high; and the former was carved most often as a snake's or dragon's head. The warriors were well armed. The *byrnie*, a mail-shirt, is often mentioned in Eddic songs; so are the axe, spear, javelin, the bow and arrows and the sword. An immense joy in battle breathes through the earliest Norse literature, which has scarce its like in any other literature; and we know that the language recognized a peculiar battle fury, a madness by which men were seized and which went by the name of "berserk's way" (*berserksgangr*). The courage of the Viking was proof against anything, even as a rule against superstitious terrors. He was unfortunately hardly less marked for cruelty and faithlessness. It is also true, however, that they showed a capacity for government, and in times of peace for peaceful organization. Normandy was the best-governed part of France in the 11th century; and the Danes in East Anglia and the Five Boroughs developed a form of society remarkable for its stability amid changing political conditions. Nevertheless, the significance of the Vikings in the history of western Europe lies less in the communities which they founded than in the stimulus given by their raids to the new military organization of society out of which feudalism was presently to arise.

VIKRAMĀDITYA, a legendary Hindu king of Uzjain, who is supposed to have given his name to the Vikram Samvat, the era which is used all over northern India, except in Bengal, and at whose court the "nine gems" of Sanskrit literature are also supposed to have flourished. The Vikram era is reckoned from the vernal equinox of the year 57 B.C., but there is no evidence that that date corresponds with any event in the life of an actual king. As a matter of fact, all dates in this era down to the 10th

century never use the word Vikram, but that of Malava instead, that being the tribe that gives its name to Malwa. The name Vikramaditya simply means "sun of power," and was adopted by several Hindu kings, of whom Chandragupta II. (Chandragupta Vikramaditya), who ascended the throne of the Guptas about A.D. 375, approaches most nearly to the legend.

See Alexander Cunningham, *Book of Indian Eras* (1883); and Vincent Smith, *Early History of India* (1904).

VILL, the Anglicized form of the word *villa,* used in Latin documents to translate the Anglo-Saxon *tun,* township. Ultimately "vill" and "township" became regarded as equivalent terms, and so remained in legal use until the ecclesiastical parish became regarded as the normal unit of local administration. In classical Latin *villa* had meant "country-house," "farm," "villa" (*see* VILLA); but even by the 3rd century it had acquired the sense of "village." Later it even displaced *civitas,* for city; thus Rutilius Namatianus in his *Itinerarium* speaks of *villae ingentes, oppida parva;* whence the French *ville* (*see* Du Cange, *Glossarium lat. s.v.* Villa). In the Frankish empire *villa* was also used of the royal and imperial palaces or seats with their appurtenances. In the sense of a small collection of habitations the word came into general use in England in the French form "village." From *villa,* too, are derived villein and villeinage (*q.v.*).

VILLA, FRANCISCO (*"Pancho"*) (1877–1923), Mexican revolutionary general, born at Rio Grande, state of Durango, Mexico, Oct. 4, 1877. As a youth without a home, roaming and thieving, he gathered around him a band of rough followers and changed his real name, Doroteo Arango, to that of a bandit once notorious in his region. He headed a well-organized ring of cattle rustlers operating in the northern states and this caused a price to be placed on his head by the Diaz Government. He was, therefore, very willing in 1910 to join Madero in his revolt against Diaz. Villa was captured by Gen. Victoriano Huerta during the campaign but later escaped into Texas. In 1914 he reentered Mexico to join forces with Gen. Venustiano Carranza (*q.v.*) against Huerta who had in the meantime overthrown Francisco Madero (*q.v.*) and seized the presidency. The two generals drove Huerta from the country but in the moment of triumph could not agree between themselves. Carranza refused to treat with Villa, regarding him as a mere bandit and not trusting his intentions. Villa marched into Mexico City and Carranza fled to Vera Cruz. But Obregon (*q.v.*), Carranza's chief general, succeeded in driving Villa out of Mexico City and pursued him relentlessly until he took refuge in the mountains of the northern states. The United States recognized Carranza's Government and Villa, feeling he had been duped, developed a hatred for the "gringos" which led to his later outrages. On Mar. 9, 1916, with some 400 men he crossed the U.S. border and raided Columbus, N. Mex., killing 16 citizens and partly burning the town. The next day President Wilson ordered a force into Mexico to capture Villa and his band. It was expected that Carranza would co-operate in the pursuit of his enemy but instead he voiced his objections to the entrance of U.S. troops and on June 17th notified Gen. Pershing that further invasion would be resisted by arms. The American troops withdrew without effecting their object. Villa ceased to be an international menace but remained under arms until the Federals in 1920 bought his retirement with the gift of a large estate. On July 20, 1923, his automobile was swept by a shower of bullets and he and his three companions were killed.

VILLA, the Latin word (diminutive of *vicus,* a village) for a country-house. The word is loosely and incorrectly used, especially in England, for small detached or semi-detached suburban houses. In its correct usage, however, it signifies a summer residence of great extent, especially in Italy, or one in which Italian influence is dominant. References to the villa are constantly made by Roman writers. Cicero is said to have possessed no less than seven villas, the oldest of which was near Arpinum; Pliny the younger had three or four, two of which he described at length in his letters; that at Tusculum and that near Laurentium. The remains of the villa of Hadrian at Tivoli, which covered an area over 7 m. long and in which reproductions were made of all the most celebrated buildings he had seen during his travels, and the villas of the 16th century on similar sites, such as the Villa d'Este near Tivoli, enable one to form some idea of the exceptional beauty of the positions selected and of the splendour of the structures which enriched them. Literary descriptions, as well as existing remains, reveal the house proper of the Roman villa as a rather rambling building designed to take advantage of breeze and view, rather than to be symmetrical. Long colonnades were frequent, there were occasional towers, and the building was often on more than one level. R. Lanciani (*Ancient Rome in the Light of Recent Excavations,* 279 ff.) states that the Casino del Ligorio (Villa Pia) in the Vatican gardens (1558–62), by P. Ligorio, and the Barberini villa at Castel Gandolfo of all existing Renaissance villas most closely resemble their Roman prototypes. Such villas were not limited to Italy but are found throughout the empire.

According to Pliny, there were two kinds of villas, the *villa urbana,* which was a country-seat and the *villa rustica,* the farmhouse. The Villa Boscoreale near Pompeii, which was excavated in 1893–94, is an example of the *villa rustica,* in which the principal room was the kitchen, with the bakery and stables beyond and room for the wine presses, oil presses, hand mill, etc. The villas near Rome were all built on hilly sites, so that the laying out of the ground in terraces formed a very important element in their design, and this forms the chief attraction of the Italian villas of the 16th century, among which the following are the best known: the Villa Madama, the design of which, attributed to Raphael, was carried out by Giulio Romano in 1520; the Villa Medici (1540); the Villa Albani, near the Porta Salaria; the Borghese; the Doria Pamphili (1650); the Villa di Papa Giulio (1550), designed by Vignola; the Aldobrandini (1598–1603) by G. della Porta; the Falconieri (1546) and the Mondragone Villas (1573–75) at Frascati, and the Villa d'Este near Tivoli (1549), by P. Ligorio, in which the terraces and staircases are of great ingenuity and beauty. In the proximity of other towns in Italy there are numerous villas, of which the example best known is that of the Villa Rotunda or Capra, by A. Palladio, near Vicenza, which was copied by Lord Burlington in his house at Chiswick.

The Italian villas of the 16th and 17th centuries, like those of Roman times, included not only the country residence, but all the other buildings on the estate, such as bridges, casinos, pavilions and small temples, which were utilized as summer-houses; and these seem to have had a certain influence in England, which may account for the numerous imitations in the large parks in England, as also the laying out of terraces, grottos and formal gardens. In France the same influence was felt, and at Fontainebleau, Versailles (1667–88), Meudon and other royal palaces, Le Nôtre transformed the parks surrounding them and introduced many Italian features.

VILLACH, an old town in Carinthia, Austria, on the Drava at the western end of the basin of Klagenfurt (*q.v.*). Since it lies on one of the through routes from Vienna to Italy a great deal of traffic still passes through the town. It is the timber trade centre for Italy and manufactures lead wares based upon the very rich lead-mines of Bleiberg, about 9 m. west of the town. The town is a centre for tourist traffic to the surrounding Alpine highlands. The 15th century church of St. Jacob in Gothic style has a tower about 315 ft. high. Pop. (1923), 22,100. Warmbad Villach, a watering-place with hot sulphur baths, and Mittewald, a favourite summer resort, whence the ascent of the Dobratsch can be made, are in the neighbourhood of Villach. Some of the prettiest Carinthian lakes are to be found near Villach, among others the Ossiacher-see.

VILLA DEL PILAR, a city of Paraguay, 104 m. south of Asuncion, on the left bank of the navigable river Paraguay. Pop.

(1929) about 8,000. Villa del Pilar is a thriving city, containing barracks, law courts, a national college, several schools and a branch of the Agricultural Bank. It is in a district producing tobacco, yerba maté, hides and oranges. It has a good harbour and is served by steamer and by the Paraguay Central railway.

VILLAFRANCA DI VERONA, a town of Venetia, Italy, in the province of Verona, 11 m. S.S.W. of Verona, on the railway to Mantua, 174 ft. above sea-level. Pop. (1921), 9,968 (town); 12,174 (commune). It has considerable silk industries. Here preliminaries of peace were signed between Napoleon III. and the Austrians in 1859 after the battle of Solferino. Five miles to the N. is Custozza, where the Italians were defeated by the Austrians in 1848 and 1866.

VILLAGE COMMUNITIES. The study of village communities has become one of the fundamental methods of discussing the ancient history of institutions. It will be sufficient to confine the present inquiry to the varieties presented by nations of Aryan race, not because greater importance is to be attached to these nations than to other branches of humankind, although this view might also be reasonably urged, but principally because the Aryan race in its history has gone through all sorts of experiences, and the data gathered from its historical life can be tolerably well ascertained.

The best way seems to be to select some typical examples, chiefly from the domain of Celtic, Slavonic and Germanic social history, and to try to interpret them in regard to the general conditions in which communal institutions originate, grow and decay. As the principal problem will consist in ascertaining how far land was held in common instead of by individuals, it is advisable to look out for instances in which this element of holding in common is very clearly expressed. We ought to get, as it were, acclimatized to the mental atmosphere of such social arrangements in order to counteract a very natural but most pernicious bent prompting one to apply to the conditions of the past the key of our modern views and habitual notions. A certain acquaintance with the structure of Celtic society, more especially the society of ancient Wales, is likely to make clear from the outset to what extent the husbandry and law of an Aryan race may depend on institutions in which the individual factor is greatly reduced, while the union first of kinsmen and then of neighbours plays a most decisive part.

Seebohm called our attention to the interesting surveys of Welsh tracts of country made in the 14th century, soon after these regions passed into the hands of English lords. The fragments of these surveys published by him and his commentary on them are very illuminating, but further study of the documents themselves discloses many important details and helps to correct some theories propounded on the subject. Let us take up a concrete and simple case, *e.g.*, the description of Astret Canon, a trev or township (*villata*) of the honour of Denbigh, surveyed in 1334. In the time of the native Welsh princes it was occupied entirely by a kindred (*progenies*) of free tribesmen descended from a certain Canon, the son of Lawaurgh. The kindred was subdivided into four gavells or bodies of joint-tenants. On the half-gavell of Monryk ap Canon, *e.g.*, there are no less than 16 coparceners, of whom eight possess houses. The peculiarity of this system of land tenure consists in the fact that all the tenants of these gavells derive their position on the land from the occupation of the township by their kindred, and have to trace their rights to shares in the original unit. Although the village of Astret Canon was occupied by something like 54 male tenants, the majority of whom were settled in houses of their own, it continued to form a unit both in regard to the payment of land tax and other services and payments, and also in respect of the possession and usage of the soil. On the other hand, movable property is owned in severalty. Services have to be apportioned among the members of the kindreds according to the number of heads of cattle owned by them. From the description of another township—Pireyon—we hear that gavells ought to be considered as equal shares in respect of the arable, the wood and the waste of the township. If the shares were reduced into acres there would have fallen to each of the eight gavells of Pireyon 91ac., one rood and a half and six perches of arable and woodland, and 53½ac. and half a rood of waste land. But as a matter of fact the rights of the tenants of the gavell were realized not through the appropriation of definite acres, but as proportionate opportunities in regard to tillage and as to usages in pasture, wood and waste. Pastoral habits must have greatly contributed to give the system of land-holding its peculiar character. It was not necessary, it would have been even harmful, to subdivide sharply the area on which the herds of cows and the flocks of sheep and goats were grazing.

We do not notice any systematic equalization between members of the tribal communities of the trevs. In fact, both differences in the ownership of cattle and differences of tribal standing, established by complex reckonings of pedigree and of social rank, led to marked inequalities. But there was also the notion of birthright, and we find in the laws that every free tribesman considered himself entitled to claim from his kindred grazing facilities and five erws for tillage. Such a claim could be made unconditionally only at a time when there was a superabundance of land to dispose of. In the 14th century, to which our typical descriptions refer, this state of things had ceased to be universal. Although great tracts of Welsh land were undoubtedly still in a state of wilderness, the soil in more conveniently situated regions was beginning to be scarce, and considerable pressure of population was already felt, with a consequent transition from pastoral pursuits to agriculture.

Although there are no rearrangements or redivision within the tribe as a whole, inside every gavell, representing more narrow circles of kinsmen, usually the descendants of one great-grandfather, *i.e.*, second cousins, the shares are shifted and readjusted according to one of two systems. In one case, that of the trev-cyvriv or joint-account village, every man receives "as much as another yet not of equal value"—which means, of course, that the members of such communities were provided with equal allotments, but left to make the best of them, each according to chance and ability. This practice of reallotment was, however, restricted in the 14th century to taeog trevs, to villages occupied by half-free settlers. The free tribesmen, the *priodarii* of Wales, held by *daddenhud,* were reallotted shares within the trev on the coming of each new generation or, conversely, on the going out, the dying out, of each older generation. In other words: at the demise of the last of the grandfathers in a gavell, all the fathers took equal rank and claimed equal shares, although formerly some of the portions had been distributed equally only between the grandfathers or their offspring (*stirps*). The right to claim redivision held good only within the circle of second cousins.

Another fact which is brought out with complete evidence by the Welsh Surveys is that the tenure is ascribed to communities of kinsmen and not to chiefs or headmen. The latter certainly existed and had exerted a powerful influence on the disposal of common land as well as on government and justice. But in the view of the 14th-century surveys each township is owned not by this or the other elder, but by numerous bodies of coparceners. In this way there is a clear attribution of rights of communal ownership, and not merely of rights of maintenance.

Let us now compare this description of Celtic tribal tenure with Slavonic institutions. The most striking modern examples of tribal communities settled on a territorial basis are presented by the history of the Southern Slavs in the Balkan Peninsula and in Austria, of Slovenes, Croats, Serbs and Bulgarians, but it is easy to trace customs of the same kind in the memories of Western Slavs conquered by Germans, of the Poles and of the different subdivisions of the Russians. A good clue to the subject is provided by a Serb proverb which says that *a man by himself is bound to be a martyr.* The Slavs of the mountainous regions of the Balkans and of the Alps in their stubborn struggle with nature and with human enemies have clustered and still cluster to some extent in closely united and widely spreading brotherhoods (*bratstva*) and tribes (*plemena*). Some of these brotherhoods derive their names from a real or supposed common ancestor, and are composed of relatives as well as of affiliated strangers. They number sometimes hundreds of members, of guns, as the fighting males are characteristically called. Such are the

Vuktići, Kovacevići,—as one might say in Old English the Vukotings or Kovachevings,—of Montenegro. The dwellings, fields, and pasturages of these brotherhoods or kindreds are scattered over the country. But there was the closest union in war, revenge, funeral rites, marriage arrangements, provision for the poor and for those who stood in need of special help, as in case of fires, inundations and the like. And corresponding to this union there existed a strong feeling of unity in regard to property, especially property in land. Although ownership was divided among the different families, a kind of superior or eminent domain stretched over the whole of the *bratstvo*, and was expressed in the participation in common in pasture and wood, in the right to control alienations of land and to exercise pre-emption.

As the Welsh kindreds were subdivided into gavells formed of extended family communities, even so the Bosnian, Montenegrin, Serbian and Slovene tribes fell into house communities, *Kućas, Zadrugas*, which were built up on the principle of keeping blood-relatives and their property together as long as possible. They consisted generally of some 15 to 20 grown-up persons, some six or seven first and second cousins with their wives and children, living in a hamlet around the central house of the *domaćin*, the house leader. In some instances the number of coparceners increased to 50 or even to 70. The members of the united house community, which in fact is a small village or hamlet, joined in meals and work. Their rights in the undivided household of the hamlet were apportioned according to the pedigree, *i.e.*, this apportionment took account first of the *stirpes* or extant descendants of former scions of the family, so that, say, the offspring of each of two grandfathers who had been brothers were considered as equal sharers although the *stirps*, the stock, of one was represented only by one person, while the *stirps* of the other had grown to consist of two uncles and of three nephews all alive. There was no resettlement of shares, as in the case of Wales, but the life of the house community while it existed unbroken led to work in common, the contributions to which were regulated by common consent and supervised by the leader. Grounds, houses, implements of agriculture (ploughs, oxen, carts) and of viniculture—casks, cauldrons for the making of brandy, etc.—were considered to be common capital and ought not to be sold unless by common consent. Divisions were not prohibited. Naturally a family had to divide sooner or later, and the shares had to be made real, to be converted into fields and vineyards. But this was an event which marked, as it were, the close of the regular existence of one union and the birth of similar unions derived from it. As a rule, the *kuća* kept together as long as it could, because co-operation was needed and isolation dangerous—for economic considerations as well as for the sake of defence.

Attention, however, should be called more particularly to the parallel phenomena in the social history of the Russians, where the conditions seem to stand out in specially strong contrast with those prevailing among the mountain Slavs of the Balkans and of the Alps. In the enormous extent of Russia we have to reckon with widely different geographical and racial areas, among others, with the Steppe settlements of the so-called Little Russians in the Ukraine, and the forest settlements of the Great Russians in the north. In spite of great divergencies the economic history of all these branches of Slavonic stock gravitates towards one main type, viz., towards rural unions of kinsmen, on the basis of enlarged households. In the south the typical village settlement is the *dvorišće*, the big court or hamlet consisting of some four to eight related families holding together; in the north it is the *pećišće*, the big oven, a hamlet of somewhat smaller size in which three to five families are closely united for purposes of common husbandry.

Another fact to be noticed is the tendency to form artificial associations on the pattern of the prevailing unions of kinsmen. People who have no blood-relations to appeal to for clearing the waste, for providing the necessary capital in the way of cattle and plough implements, for raising and fitting out buildings, join in order to carry on these economic undertakings, and also to help each other against aggressors. The members of these voluntary associations, which at once call to mind German, Norse and English gilds, are called "siabri," "skladniki," and the gilds themselves "spólkie," in south Russia. In a district of the Ukraine called the "Ratensky Sharostvo" there were no fewer than 278 such gilds interchanging with natural kindreds. The organization of all these unions could in no way be called patriarchal. Even in cases when there is a definite elder or headman (*bolshoy*), he was only the first among equals and exercised only a limited authority over his fellows: all the important decisions had to be taken by the council of the community.

In Great Russia, in the districts gathered under the sway of the Moscow tsars, the basis of the household community and of the rural settlements which sprang from it was modified in another direction. The entire agricultural population was subjected to strict supervision and coercive measures for purposes of military organization and taxation. Society was drilled into uniformity and service on the principle that every man has to serve the tsar, the upper class in war and civil administration, the lower class by agricultural labour. A consequence of the heavy burden laid on the land and of the growth of a landed aristocracy was a change in the management of land allotments. They became as much a badge of service and a basis for fiscal requirements as a means of livelihood. The result was the practice of reallotments according to the strength and the needs of different families. The shifting of arable (*peredel*) was not in this case a reapportionment of rights, but a consequence of the correspondence between rights and obligations.

Let us now pass to village communities in Teutonic countries, including England. A convenient starting-point is afforded by the social and economic conditions of the southern part of Jutland. The Saxon or Ditmarschen portion of this region gives us an opportunity of observing the effects of an extended and highly systematized tribal organization on Germanic soil. The independence of this northern peasant republic, which reminds one of the Swiss cantons, lasted until the time of the Reformation. We find the Ditmarschen organized in the 15th, as they had been in the 10th century, in a number of large kindreds, partly composed of relatives by blood and partly of "cousins" who had joined them. The membership of these kindreds is based on agnatic ties—that is, on relationship through males—or on affiliation as a substitute for such agnatic kinship. The families or households are grouped into brotherhoods, and these again to clans or "Schlachten" (*Geschlechter*), corresponding to Roman *gentes*. Some of them could put as many as 500 warriors in the field. They took their names from ancestors and chieftains: the Wollersmannen, Hennemannen, Jerremannen, etc.—*i.e.*, the men of Woll, the men of Henne, the men of Jerre. In spite of these personal names the organization of the clans was by no means a monarchical one: it was based on the participation of the full-grown fighting men in the government of each clan and on a council of co-opted elders at the head of the entire federation.

Let us notice the influence of this tribal organization on husbandry and property. The regular economic arrangement was an open-field one based on a three-field and similar systems. The furlongs were divided into intermixed strips with compulsory rotation on the usual pattern. And it is interesting to notice that in these economic surroundings indivisible holdings corresponding to the organic unities required for efficient agriculture arose of themselves. In spite of the equal right of all coheirs to an estate, this estate does not get divided according to their numbers, but either remains undivided or else falls into such fractions, halves or fourths, as will enable the farming to be carried on successfully. The Hufe or Hof goes mostly to the eldest son, but also sometimes to the youngest, while the brothers of the heir either remain in the same household with him, generally unmarried, or leave the house after having settled with their heir, who takes charge of the holding, as to an indemnity for their relinquished claims.

This evidence is of decisive importance in regard to the formation of unified holdings; we are on entirely free soil, with no vestige whatever of manorial organization or of coercion of tenants by the lord. The Hufe, the normal holding, is preserved intact in order to secure agricultural efficiency. This "Anerben" system is widely spread all through Germany. The question whether the

eldest or the youngest succeeds is a subordinate one. Anyhow, manorial authority is not necessary to produce the limitation of the rights of succession to land and the creation of the system of holdings, although this has been often asserted, and one of the arguments for a servile origin of village communities turns on a supposed incompatibility between the unified succession and the equal rights of free coheirs.

We need not speak at any length about other parts of Germany, as space does not permit of a description of the innumerable combinations of communal and individual elements in German law, but we must point out some facts from the range of Scandinavian customs. In the mountainous districts of Norway we notice the same tendency towards the unification of holdings as in the plains and hills of Schleswig and Holstein. The bönder of Gudbrandsdalen and Telemarken, the free peasantry tilling the soil and pasturing herds on the slopes of the hills from the days of Harold Hárfagr to our own times, sit in *Odalgaards*, or freehold estates, from which supernumerary heirs are removed on receiving some indemnity, and which are protected from alienation into strange hands by the privilege of pre-emption exercised by relatives of the seller. Equally suggestive are some facts on the Danish side of the straits, viz., the arrangements of the *bóls* which correspond to the hides and virgates of England and to the Hufen of Germany. Here again we have to do with normal holdings independent of the number of coheirs, but dependent on the requirements of agriculture—on the plough and oxen, on certain constant relations between the arable of an estate and its outlying commons, meadows and woods. The ból does not stand by itself like the Norwegian gaard, but is fitted into a very close union with neighbouring bóls of the same kind. Practices of coaration, of open-field intermixture, of compulsory rotation of lot-meadows, of stinting the commons, arise of themselves in the villages of Denmark and Sweden.

We catch a glimpse, to begin with, of a method of dividing fields which was considered archaic even in those early times, the so-called "forniskift" and "hamarskift." The two principal features of this method are the irregularity of the resulting shapes of plots and the temporary character of their occupation. The first observation may be substantiated by a description like that of Laasby in Jutland: "These lands are to that extent scattered and intermixed by the joint owners that it cannot be said for certain what (or how much) they are." Swedish documents, on the other hand, speak expressly of practices of shifting arable and meadows periodically, sometimes year by year.

Now the uncertainty of these practices based on occupation became in process of time a most inconvenient feature of the situation and evidently led to constant wrangling as to rights and boundaries. The description of Laasby which I have just quoted ends with the significant remark: "They should be compelled to make allotment by the cord." This making of allotments by the cord is the process of rebning, from *reb*, the surveyor's cord, and the juridical procedure necessary for it was called "solskift"—because it was a division following the course of the sun.

The two fundamental positions from which this form of allotment proceeds are: (1) that the whole area of the village is common land (*faellesjord*), which has to be lotted out to the single householders; (2) that the partition should result in the creation of equal holdings of normal size (bóls). In some cases we can actually recognize the effect of these allotments by ancient solskift in the 18th century, at a time when the Danish enclosure acts produced a second general revolution in land tenure.

The 12 oldest inhabitants, elected as sworn arbitrators for effecting the allotment, begin their work by throwing together into one mass all the grounds owned by the members of the community, including dwellings and farm-buildings, with the exception of some privileged plots. There is a close correspondence between the sites of houses and the shares in the field. The first operation of the surveyors consists in marking out a village green for the night-rest and pasture of the cattle employed in the tillage (*fortá*), and assigning sites to the houses of the coparceners with orchards appendant to them (tofts); every householder getting exactly as much as his neighbour. From the tofts they proceed to the fields on the customary notion that the toft is the mother of the field. The fields are disposed into furlongs and shots, as they were called in England, and divided among the members of the village with the strictest possible equality. This is effected by assigning to every householder a strip in every one of the furlongs constituting the arable of the village. Meadows were often treated as lot-meadows in the same way as in England. After such a "solskift" the peasants held their tenements in undisturbed ownership, but the eminent demesne of the village was recognized and a revision of the allotment was possible.

After having said so much about different types of village communities which occur in Europe it will be easier to analyse the incidents of English land tenure which disclose the working of similar conceptions and arrangements. Features which have been very prominent in the case of the Welsh, Slavs, Germans or Scandinavians recur in the English instances sometimes with equal force and at other times in a mitigated shape.

There are some vestiges of the purely tribal form of community on English soil. Many Saxon and Anglian place-names are derived from personal names, followed by the suffix *ing*, and closely resemble the common patronymics of Saxon and German families and kindreds. It is most probable, as Kemble supposed, that we have to do in most of these instances with tribal and family settlements, although the mere fact of belonging to a great landowner may have been at the root of some cases.

A very noticeable consequence of tribal habits in regard to landownership is presented by the difficulties which stood in the way of alienation of land by the occupiers of it. The Old English legal system did not originally admit of any alienation of folkland, land held by folkright, or, in other words, of the estates owned under the ordinary customary law of the people. Such land could not be bequeathed out of the kindred and could not be sold without the consent of the kinsmen. Such complete disabilities could not be upheld indefinitely, however, in a growing and progressive community, and we find the ancient folkright assailed from different points of view. The Church insists on the right of individual possessors to give away land for the sake of their souls; the kings grant exemption from folkright and constitute privileged estates held by charter and following in the main the rules of individualized Roman law; the wish of private persons to make provision for daughters and to deal with land as with other commodities produces constant collisions with the customary tribal views. Already, by the end of the Saxon period, transfer and alienation of land make their way everywhere, and the Norman conquest brings these features to a head by substituting the notion of tenure—*i.e.*, of an estate burdened with service to a superior—for the ancient notion of tribal folkland.

But although the tribal basis of communal arrangements was shaken and removed in England in comparatively early times, it had influenced the practices of rural husbandry and landholding, and in the modified form of the village community it survived right through the feudal period, leaving characteristic and material traces of its existence down to the present day.

To begin with, the open-field system with intermixture of strips and common rights in pasture and wood was the prevailing system in England for more than a thousand years. Under the name of champion farming it existed everywhere in the country until the Enclosure Acts of the 18th and 19th centuries put an end to it; it may be found in operation even now in some of its features in backward districts. It would have been absurd to build up these practices of compulsory rotation of crops, of a temporary relapse of plots into common pasture between harvest and ploughing time, of the interdependence of thrifty and negligent husbandmen, from the point of view of individual appropriation. On the other hand, it was the natural system for the apportionment of claims to the shareholders of an organic and perpetual joint-stock company.

Practices of shifting arable are seldom reported in English evidence. There are some traces of periodical redivisions of arable land in Northumberland: under the name of runrig such practices seem to have been not uncommon in the outer fields, the non-manured portions, of townships in Scotland, both among the

Saxon inhabitants of the lowlands and the Celtic population of the highlands. The joining of small tenants for the purpose of coaration, for the formation of the big, heavy ploughs, drawn by eight oxen, sometimes caused a shifting in the possession of strips between the coparceners of the undertaking. But, as a rule, the arable was held in severalty by the different members of the township.

On the other hand, meadows were constantly owned by entire townships and distributed between the tenements entitled to shares from year to year either by lot or according to a definite order. These practices are in full vigour in some places even at the present day. Any person living in Oxford may witness the distribution by lot on Lammas day (Aug. 1) of the Lammas meadows, that is, the meadows inclosed for the sake of raising hay-grass in the village of Yarnton, some three miles to the north of Oxford.

Let us, however, return for a moment to the arable. Although held in severalty by different owners it was subjected to all sorts of interference on the part of the village union as represented in later ages by the manorial court framing by-laws and settling the course of cultivation. It might also happen that in consequence of encroachments, disputes, and general uncertainty as to possession and boundaries, the whole distribution of the strips of arable in the various fields had to be gone over and regulated anew. In such cases, as in the Danish examples quoted before, the strips were apportioned, not to single owners, but to the normal holdings, the hides, and the actual owners had to take them in proportion to their several rights in the hides. This point is very important. It gives the English village community its peculiar stamp. It is a community not between single members or casual households, but between definite holdings constructed on a proportional scale. Although there was no provision for the admeasurement or equalization of the claims of Smith and of Brown, each hide or ploughland of a township took as much as every other hide, each virgate or yardland as every other yardland, each bovate or oxgang as every other oxgang. Now the proportions themselves, although varying in respect of the number of acres included in each of these units in different places, were constant in their relation to each other. The yardland was almost everywhere one-fourth of the hide or ploughland, and corresponded to the share of two oxen in an eight-oxen plough; the oxgang was reckoned at one-half of the yardland, and corresponded to the share of one ox in the same unit of work.

The natural composition of the holdings has its counterpart, as in Schleswig-Holstein and as in the rest of Germany, in the custom of unified succession. The English peasantry worked out customary rules of primogeniture or of so-called Borough English or claim of the youngest to the land held by his father. The German examples already adduced teach us that the device is not suggested primarily by the interest of the landlord. Unified succession takes the place of the equal rights of sons, because it is the better method for preserving the economic efficiency of the household and of the tenement corresponding to it. There are exceptions, the most notorious being that of Kentish gavelkind, but in agricultural districts the holding remains undivided as long as possible, and if it gets divided, the division follows the lines not of the casual number of coheirs, but of the organic elements of the ploughlands. Fourths and eighths arise in connection with natural fractions of the ploughteam of eight oxen.

One more feature of the situation remains to be noticed, and it is the one which is still before our eyes in all parts of the country, that is, the *commons* which have survived the wholesale process of enclosure. They were an integral part of the ancient village community from the first, because there existed the most intimate connection between the agricultural and pastoral part of husbandry in the time of the open-field system. Pasture was not treated as a commodity by itself but was mostly considered as an adjunct, as appendant to the arable, and so was the use of woods and of turf. The problem of admeasurement of pasture was regulated in the same way as that of the apportionment of arable strips, by a reference to the proportional holdings, the hides, yardlands and oxgangs of the township, and the only question to be decided was how many heads of cattle and how many sheep each hide and yardland had the right to send to the common pasturage grounds.

When in course of time the open-field system and the tenure of arable according to holdings were given up, the right of freeholders and copyholders of the old manors in which the ancient townships were, as it were, encased, still held good, but it became much more difficult to estimate and to apportion such rights.

In connection with the individualistic policy of enclosure the old writ of admeasurement of commons was abolished in 1837 (3 & 4 Will. IV.). The ordinary expedient is to make out how much commonable cattle could be kept by the tenements claiming commons through the winter. It is very characteristic and important that in the leading modern case on sufficiency of commons—in *Robertson* v. *Hartopp*—it was admitted by the Court of Appeal that the sufficiency has to be construed as a right of turning out a certain number of beasts on the common, quite apart from the number which had been actually turned out at any given time. Now a vested right has to be construed from the point of view of the time when it came into existence. The standards used to estimate such rights ought not to be drawn from modern practice, which is generally independent of common of pasture, but ought to correspond to the ordinary usages established at a time when the open-field system was in full vigour. The legal view stands thus at present, but we cannot conceal from ourselves that after all the inroads achieved by individual appropriation it is by no means certain that the reference to the rights and rules of a previous period will continue to be recognized. However this may be, in the present commons we have certainly a system which draws its roots from customs as to the origin of which legal memory does not run.

We may, in conclusion, summarize very briefly the principal results of our inquiry as to the history of European village communities. It seems that they may be stated under the following heads: (1) Primitive stages of civilization disclose in human society a strong tendency towards mutual support in economic matters as well as for the sake of defence. (2) The most natural form assumed by such unions for defence and co-operation is that of kinship. (3) In epochs of pastoral husbandry and of the beginnings of agriculture land is mainly owned by tribes, kindreds and enlarged households, while individuals enjoy only rights of usage and possession. (4) In course of time unions of neighbours are substituted for unions of kinsmen. (5) In Germanic societies the community of the township rests on the foundation of efficient holdings—bóls, hides, hufen—kept together as far as possible by rules of united or single succession. (6) The open-field system, which prevailed in the whole of Northern Europe for nearly a thousand years, was closely dependent on the customs of tribal and neighbourly unions. (7) Even now the treatment of commons represents the last manifestations of ancient communal arrangements, and it can only be reasonably and justly interpreted by reference to the law and practice of former times.

An indication of the nature of modern work on this subject will be found in Vinogradoff, *Villainage in England* (1892), *The Growth of the Manor* (1905) and *English Society in the 11th Century* (1907). (P. Vi.)

VILLALBA, a town of north-western Spain, in the province of Lugo; on the left bank of the river Ladra, one of the headstreams of the Miño, and at the junction of the main roads from Ferrol and Mondoñedo to the city of Lugo. Pop. (1920) 15,194. Villalba stands on a fertile plateau 1,500 ft. above sea-level. Cloth and pottery are manufactured, and there is some trade in grain and live stock. The nearest railway station is Otero, 15 m. S. by E. on the Lugo-Corunna line.

VILLAMEDIANA, COUNT DE (1580–1622), Spanish poet, was born at Lisbon, the son of a diplomatist. He acquired a bad reputation as a gambler and was banished from court in 1608. On his return to Spain (1617) he proved himself a fearless, pungent satirist. So great was the resentment caused by his envenomed attacks that he was once more ordered to withdraw from court in 1618. Appointed gentleman in waiting (1621) to Philip IV.'s young wife, Isabel de Bourbon, daughter of Henri IV., his

ostentatious attentions to the queen supplied his numerous foes with a weapon which was destined to destroy him. A fire broke out while his masque, *La Gloria de Niquea*, was being acted before the court on May 15, 1622, and Villamediana carried the queen to a place of safety. Suspicion deepened and on Aug. 21 he was murdered as he stepped out of his coach. The responsibility for his death was divided between Philip IV. and Olivares, and naturally the crime remained unpunished.

Villamediana's works contain not only the nervous, blighting verses which made him widely feared and hated, but a number of more serious poems embodying the most exaggerated conceits of gongorism. But, even when adopting the perverse conventions of the hour, he remains a poet of high distinction, and his satirical verses, more perfect in form, are instinct with a cold, concentrated scorn which has never been surpassed.

VILLANELLE, primarily a round song taken up by men on a farm (Lat. *villa*); originally loose in form, but afterwards arbitrarily fixed. It was a pastoral, set to a rustic dance, and had, therefore, a regular system of repeated lines. The old French villanelles, however, were irregular; the "Rosette, pour un peu d'absence" of Desportes (d. 1606), is a sort of ballade, and those of d'Urfé (d. 1625) are scarcely less lax. The rigorous form seems to have been settled by accident. Among the posthumous poems of Jean Passerat (d. 1602) several villanelles were found, of which one became so popular as to set the standard for subsequent poets. It runs thus:

"J'ai perdu ma tourterelle:
Est-ce point celle que j'oi?
Je veux aller après elle.

Tu regrettes ta femelle?
Hélas! aussi fais-je moi:
J'ai perdu ma tourterelle.

Si ton amour est fidèle,
Aussi est ferme ma foi:
Je veux aller après elle.

Ta plainte se renouvelle?
Toujours plaindre je me dois:
J'ai perdu ma tourterelle.

En ne voyant plus la belle
Plus rien de beau je ne vois:
Je veux aller après elle.

Mort, que tant de fois j'appelle,
Prends ce qui se donne à toi:
J'ai perdu ma tourterelle,
Je veux aller après elle."

For 300 years the villanelle has been written in tercets, on two rhymes, the first and the third being repeated alternately in each tercet. It is usual to confine it to five tercets, but that is not essential; it must, however, close with a quatrain, the last two lines of which are the first and third of the original tercet. Boulmier, who was the first to show that Passerat was its inventor, published collections of these poems in 1878 and 1879, and was preparing another when he died, in 1881. When, in 1877, so many of the early French forms of verse were reintroduced into English, the villanelle attracted much attention; it was simultaneously cultivated by W. E. Henley, Austin Dobson, Lang and Gosse. Henley wrote a large number, and described the form in a specimen beginning: "A dainty thing's the Villanelle." There are several examples in English of humorous villanelles, especially by Austin Dobson and by Henley.

See J. Boulmier, *Les Villanelles* (2nd ed., 1879).

VILLANI, GIOVANNI (*c.* 1275–1348), Florentine chronicler, was born at Florence of a mercantile family, and spent much of his early manhood in travelling on business in Italy, France and the Netherlands. He returned definitely to Florence before 1312, and from 1316 onwards held many important offices in his native city, and was employed on various diplomatic missions. In his last years he was involved in the bankruptcy of the Bonaccorsi, and fell into poverty. He died in 1348 in the plague epidemic described by Boccaccio.

His *Historie Fiorentine*, or *Cronica universale*, begins with Biblical times and comes down to 1348. The ground covered by the narrative, especially in the times near Villani's own, bears witness to the author's extensive travels and to the breadth of his mind. It is the cornerstone of the early mediaeval history of Florence. Villani was Guelph, but without passion; and his book is more taken up with an enquiry into what is useful and true than with party considerations. He is a chronicler, not an historian, and has but little method in his narrative. He provides information on the constitution of Florence, its customs, industries, commerce and arts; and of the chroniclers of his day he is perhaps unequalled for the value of his statistical data. The *Chronicle* has been printed by L. A. Muratori in tome xiii. of the *Rerum Italicarum Scriptores* (Milan, 1728) and has been edited by I. Moutier and F. G. Dragomanni (Florence, 1844). Other editions appeared at Trieste (1857) and at Turin in 1879. Selections have been translated into English by R. E. Selfe (2nd ed. 1906).

Balzani, *Le cronache Italiane nel medio evo* (Milan, 1884); A. Gaspary, *Geschichte der italienischen Literatur* (Berlin, 1885); O. Knoll, *Beitr. zur ital. Historiographie im 14. Jahr.* (Göttingen, 1876), and O. Hartwig, "G. Villani und die Leggenda di Messer Gianni di Procida" in H. von Sybel's *Historische Zeitschrift*. Bd. 25.

VILLANOVANS is merely a conventional term chosen by archaeologists as a distinctive and useful designation for a group of tribes exhibiting a fairly uniform civilization over a great part of Italy in the Early Iron Age (q.v.). Villanova itself, from which the name is derived, is a little village eight kilometres from Bologna, near which, between 1853 and 1855, was excavated a cemetery of previously unknown character. The burials were all cremations; the ashes of the deceased being deposited in a large jar of rough hand-made pottery, which was placed in a round hole in the ground, sometimes but not always enclosed in a rectangular cist of unhewn slabs. Inside the jar, which was of the very distinctive form shown in fig. 1, were the remains of human bones incompletely consumed by the fire; while in the layer of ashes surrounding the jars were bones of animals, together with small objects of use or ornament made of bronze, iron, amber, glass or bone.

Numerous other cemeteries of similar character have been discovered, first in the neighbourhood of Bologna, then in Etruria and the northern part of Latium. The civilization revealed in these was shown to belong to the first phases of the Iron Age, beginning about the 12th or 11th century B.C., and the general name of Villanovan was applied to it as descriptive of its homogeneous character. All these cemeteries, whatever may be the peculiarities of their local variation, are united by at least one common bond of custom; they all contain cremation burials with at most a very slight percentage of unburned bodies. In this respect they are contrasted with all the contemporary cemeteries of eastern and southern Italy, which consist exclusively of the inhumations of unburned bodies. Occasional examples of jars resembling the Villanovan burial-urn have indeed been found in Apulia and Calabria, but in these provinces they were never adopted for ceremonial purposes but simply used for carrying water. As all the tribes of eastern and southern Italy buried their dead without burning, this difference of custom implies a difference of religious belief, and probably a divergence of racial origin. This inference seems to be justified by a study of the dress, armament, arts and manufactures of the several regions, which shows the Bolognese and Etrurians to be closely allied in the principal details of their material culture, while the Apulians and the Calabrians are notably different and appear to have evolved independently from another inheritance.

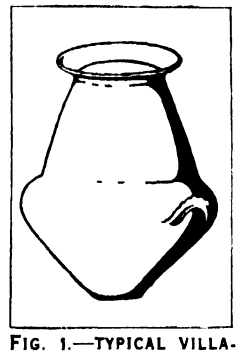

FIG. 1.—TYPICAL VILLANOVAN OSSUARY. AFTER GOZZADINI

Territorial Extension.—In the north the territory of the Villanovans began at the river Reno and extended from the Panaro on the west to Rimini on the east. South of Rimini they

never inhabited the east coast but on the west of the mountainous backbone they extended their sway over the whole of Etruria and down into Latium as far as the Alban hills. Roughly speaking, therefore, they occupied about a third of Italy north of Rome, the other two-thirds being taken up principally by the kindred civilizations of the Comacines (q.v.) and Atestines (q.v.) on the north and by a hostile block of Picenes on the east. (*See* PICENES.) It is useful to distinguish the inhabitants of the Bolognese region as the northern Villanovans, while those of Etruria and the adjoining parts of Latium may be termed the southern Villanovans.

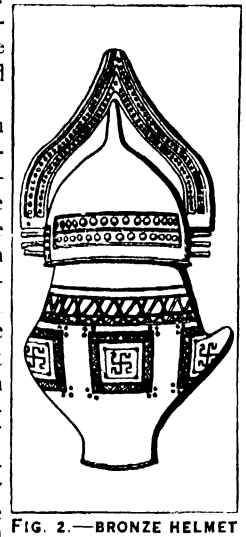

FIG. 2.—BRONZE HELMET

Theories of Origin.—As to the origin and racial affinities of this group of cremating tribes, which exercised such a profound influence upon Italy before the arrival of Etruscans or Greeks, there are two rival theories. To neither of these can exclusive preference be given; future discoveries must decide between them, and it is not likely that any final decision will be reached for many years. But on the most essential points the two theories are in complete agreement. Whether the Villanovans were direct lineal descendants of the builders of the Terremare or only a kindred race which did not enter Italy until the dawn of the Iron Age, three points are generally admitted: (1) that all the Villanovans are related by some degree of kinship as members of the same original family, (2) that their ultimate parentage is to be traced to the peoples of central Europe then settled on the middle Danube, and (3) that the direction of their occupation of Italy was from north to south.

However, while we are very fully informed as to the character of Villanovan culture in Italy itself, yet the nature and degree of its connections with the countries east and north of the Adriatic remain obscure. The relationship to Hallstatt in particular is far less close than might have been expected. To some extent, however, this may be explained by the circumstance that no graves at Hallstatt are as early as the beginnings of the Villanovan period. The very earliest graves of this people in Italy have been found in the mountainous tract of Tolfa and Allumiere on the coast of southern Etruria. They form a valuable link connecting the cemeteries of the Alban hills and the earliest graves of the Forum at Rome with sites like Corneto and Vetulonia. The cemeteries of Tolfa, Castel Gandolfo, Grottaferrata and two or three graves in the Forum may be assigned to the 12th and 11th centuries B.C.

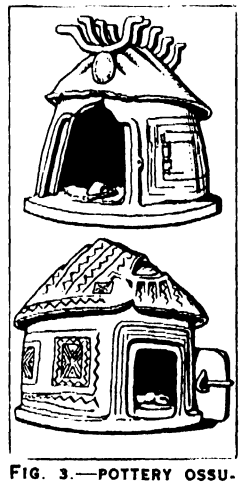

FIG. 3.—POTTERY OSSUARIES IN FORM OF HUTS

The First Benacci sites at Bologna begin in the 11th century, and are followed in due order by the Second Benacci, dating from 950 to 700 B.C., and by the Arnoaldi which covers 700 to 500 B.C. Cemeteries corresponding in date and style to the First and Second Benacci periods of Bologna have been found at various sites scattered over the country between Tolfa and Florence or Pisa. But the third, or Arnoaldi period, is not represented south of the Arno, because the southern Villanovans had been subjugated by the Etruscans before 700 B.C. and their civilization transformed by their conquerors. In the north the history is different, for as the Etruscans did not cross the Apennines to found any colonies there before the end of the 6th century, the Bolognese Villanovans survived as a distinct and highly characterized people till after 500 B.C.

Local Differences.—In spite of a close family resemblance in their general character there were many local differences of custom and practice. Thus the northern Villanovans invariably used the burial urn shown in fig. 1 and covered it with a pottery bowl. But on various Etrurian sites this standardized jar was not employed at all, and on others where it was used the jar was occasionally covered with a helmet instead of a bowl. To this practice is due the survival of some magnificent examples of 9th century bronze work, such as the helmet shown here (fig. 2).

Another alternative form of burial urn used by the south but not in the north was the pottery hut, a miniature model of the dwelling house, of which two examples are shown (fig. 3). Neither of those variations from their ceremonial form was adopted by the Bolognese, who retained the standard type of ritual urn with the most rigid conservatism, though the potters somewhat modified its outline in the course of centuries.

FIG. 4.—OSSUARY OF HAMMERED BRONZE

One of the most notable traits common to both branches of the Villanovans is their remarkable skill in metal work. Helmets such as fig. 2, large bronze vessels like fig. 4, or belts like that seen in fig. 8 were freely made in the 9th century B.C. by a primitive but extremely effective process. The technique consists in the hammering by hand of thin sheets of copper or bronze, which were then bent round and fastened together with rivets. Lines of these rivets generally form the principal decoration, which

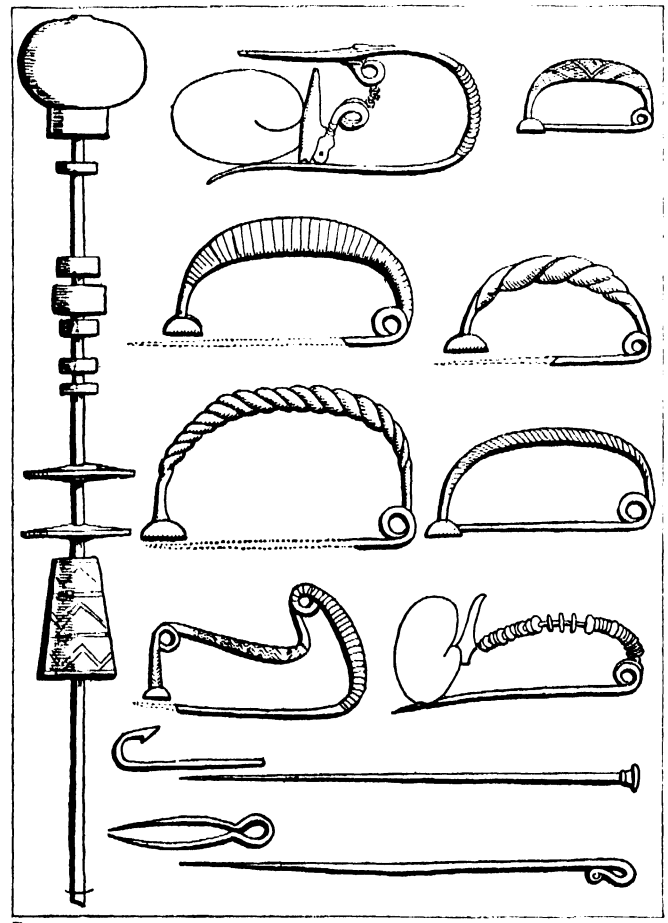

FIG. 5.—THE FIRST BENACCI PERIOD AT BOLOGNA, SHOWING BRONZE FIBULAE AND PINS, HOOK, TWEEZERS, OBJECT OF UNKNOWN USE WITH BRONZE STAFF AND HEAD, AND DISCS OF AMBER

is extremely simple. This process is quite unlike anything used by the people of the Terremare, and it was probably learned by the Villanovans in their original transalpine homes. That they traded with the Danube region at this date is shown by the bronze swords of Hallstatt type with hilts terminating in spiral volutes, which have been found in small numbers at various places in Etruria as well as farther north. The skill of the Villanovan coppersmiths ex-

plains the rapid development of every form of metal-work when the mines of Tuscany and Elba were more freely exploited in the 8th and following centuries. The Etruscans by themselves never constituted any large number of persons; they formed a small ruling aristocracy but the backbone of the population was always Villanovan. For this reason it is important to realize the high grade of that native Italian civilization upon which the Etruscan was grafted. Artistic spirit and enterprise, new ideas of decoration and ornament, improvements in technique were all contributed by the Etruscans, but there already existed a high standard of primitive workmanship and a long tradition amongst the native workmen whom they found in the country. The Villanovans in fact had attained a stage of civilization which must be considered quite high long before they came under any influences from the Aegean or the Orient. They owed a good deal to their intercourse with central Europe but nothing whatsoever to any of the Mediterranean peoples. As early as the 10th century B.C. the existence of considerable commerce with countries north of the Alps is proved by the presence of Baltic amber as well as of glass beads in the tombs. This is the natural continuation of a traffic which began in the Bronze Age, when Italy freely exported her own models of weapons to foreign countries.

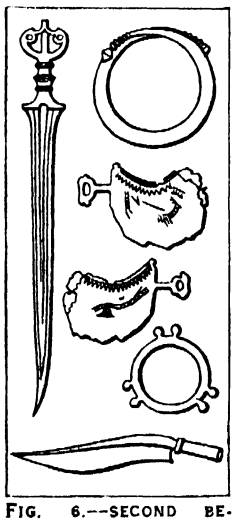

FIG. 6.—SECOND BENACCI PERIOD AT BOLOGNA, SHOWING SWORD, ARMLETS, RAZOR ENGRAVED WITH BOAT AND HAFTED AXE, PIKE, ALL OF BRONZE

In its general aspect the whole character of the civilization recalls that of central Europe. Art is still in its infancy, and decoration is entirely confined to a few geometric motives. Even on the pottery, which affords the greatest scope for decoration, the only schemes of ornament are incised rectilinear patterns of the simplest kind. All over Europe the same geometric school of design is dominant at this period. The first traces of naturalism in Italy begin to appear on a few rare pieces of imported pottery brought in from the Aegean during the 8th century, and on Etruscan bronze work of the same period.

The everyday life of the Villanovans may to some extent be estimated by the products of their tombs and dwellings. It may be inferred that they lived in small villages composed of wattle and daub huts roofed with wooden beams. Their clothing was of a thick material, doubtless wool spun from the fleeces of their own sheep on their own bronze distaffs and spindles. It was fastened with strong fibulae of bronze, or, in the later periods, of iron. These fibulae, often decorated with pieces of bone, amber or glass, follow a distinct course of evolution, which is a great help in tracing the stages of chronology. The Villanovans were well acquainted with the horse—bronze bits are very frequent even in the earliest cemeteries—but there is no evidence that they used chariots, which were first introduced by the Etruscans. That they were of warlike character is amply proved by the constant occurrence of swords, battle-axes and daggers. Defensive armour, however, was rare and confined to the use of helmets. The practice of hunting is vouched for by the bones of wild animals found in the ashes of the funeral feasts, and the occurrence of sheep and oxen shows familiarity with the farm.

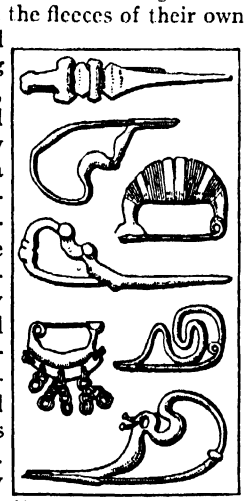

FIG. 7.—SECOND BENACCI PERIOD AT BOLOGNA, SHOWING BRONZE FIBULAE OR SAFETY-PINS

As manufacturers these tribes were important principally for their metal-work. Pottery was made everywhere, but only for use in Italy, and seldom exported even to a neighbouring community. Until the 7th century it was all hand-made, but about 700 B.C. the wheel was introduced and with it came new processes of decoration. By the 7th century, however, the only Villanovans who retained their independence were the northern branch about Bologna. All Etruria and Latium had now been conquered by the Etruscans; but north of the Apennines the Bolognese continued to develop their provincial life without any interference from the foreigner. They entered, however, into peaceful trade relations with their new neighbours and acquired an occasional ornament or

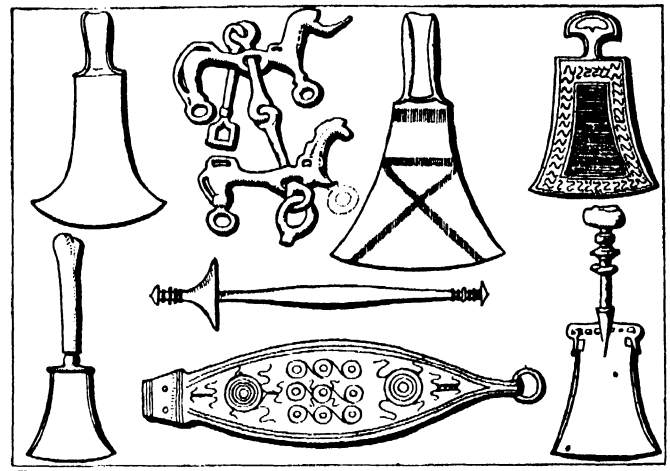

FIG. 8.—SECOND BENACCI PERIOD AT BOLOGNA, SHOWING AXES, HORSE-BIT, TINTINNABULUM, DISTAFF, GIRDLE, ALL OF BRONZE; AND TWO AXES WITH HANDLES OF BONE

piece of Etruscan jewellery from which it is possible to establish some valuable synchronisms of dating. When the Etruscans eventually crossed the Apennines and founded their colony of Felsina at Bologna about 500 B.C., they did not expel nor at once absorb the older inhabitants. For some generations the two peoples lived side by side, each preserving its own individuality, dwelling in separate settlements and burying their dead in separate cemeteries. It is only very rarely at Bologna that an Etruscan object is found in a Villanovan grave or vice versa. But gradually the superior civilization ousted the other, and before the Gauls put an end to the existence of both communities at Bologna in the 4th century Villanovanism was practically extinct. Its survival, however, in this northern region for nearly three centuries after it had been extinguished in Etruria affords a most valuable study of the process by which, presumably, the Etruscans gradually replaced and dominated the Villanovans in other parts of the country. The archaeological history of Bologna has made it possible to solve the principal difficulties which beset students of this subject in the last generation. We can now distinguish between the products of the Villanovans and those of the Etruscans and give due value and prominence to the older people whose contribution to the civilization of early Italy had so long been neglected or undervalued.

See D. Randall-MacIver, *Villanovans and Early Etruscans* (1924), which gives all the original Italian sources; A. Grenier, *Bologne villanovienne et étrusque* (1912), which is the most closely detailed study of the northern region; F. von Duhn, *Italische Gräberkunde* (1924), which deals with the subject incidentally rather than as a correlated whole. (D. R.-M.)

VILLANUEVA DE LA SERENA, a town of western Spain, in the province of Badajoz, near the left bank of the river Guadiana, and on the Madrid-Badajoz railway. Pop. (1920) 14,857. Villanueva is the chief town of La Serena, locally celebrated for red wine and melons. Grain and hemp are also cultivated, and live stock extensively reared in the neighbourhood.

VILLANUEVA Y GELTRÚ, a seaport of north-eastern Spain, in the province of Barcelona; on the Barcelona-Tarragona section of the coast railway. Pop. (1920) 13,720. Villanueva is a busy modern town, with manufactures of cotton, woollen and linen goods, and of paper. It has also iron foundries and an important agricultural trade. The harbour affords safe and deep anchorage; it is a lifeboat station and the headquarters of a large fishing fleet. The coasting trade is also considerable. Villanueva has a museum, founded by the Catalan poet and historian, Victor Balaguer (1824–1901), which contains a large library, including

not only numerous historical works but also many valuable mss.

VILLARD, HENRY (1835–1900), American journalist and financier, was born in Speyer, Rhenish Bavaria, Apr. 10, 1835. He emigrated to America in 1853 and engaged in journalistic work for German-American newspapers and later for leading American dailies. He reported the Lincoln-Douglas debates for eastern newspapers, the Pikes Peak gold rush for the Cincinnati *Daily Commercial* and the Civil War from the field of action for the New York *Herald* and New York *Tribune*. In 1881 he purchased the *Nation* and the New York *Evening Post*.

Through acting as agent for German bondholders he became interested in railway finance. In 1875 he aided in reorganizing the Oregon and California Railroad and the Oregon Steamship company and in 1876 became president of both companies. He was receiver of the Kansas Pacific Railroad in 1876–78. In 1879 he organized the Oregon Railway and Navigation Company which built a line along the Columbia river from Portland to Wallula. In 1881 Villard secured control of the Northern Pacific and became its president. Its transcontinental line was completed under his management but the costs so far exceeded the estimate that both Villard and the road became insolvent in 1883 and Villard was removed from the presidency. He later recouped his losses so that from 1889–1893 he served as chairman of the board of directors of the same company. In 1890 he bought the Edison Lamp Co. at Newark, N.J., and the Edison Machine Works at Schenectady, N.Y., and formed them into the Edison General Electric Co. of which he was president until its reorganization in 1893 as the General Electric Co. He died at Dobbs Ferry, N.Y., Nov. 12, 1900.

See *Memoirs of Henry Villard* (2 vols., 1904).

VILLARET DE JOYEUSE, LOUIS THOMAS (1750–1812), French admiral, was born at Auch. He served for some time in the royal guard, but had to leave after killing one of his comrades in a duel. He then entered the navy, and in 1773 was lieutenant on the "Atalante" in Indian waters. In 1778 after the siege of Pondicherry, he was promoted captain. He took part in the battle of Cuddalore, and in 1781 was taken prisoner. He was released in 1783, and did not emigrate during the Revolution. In 1791 he commanded the "Prudente" at San Domingo, and in 1794 was appointed rear-admiral and assisted the Conventional, St. André, in the reorganization of the fleet. Villaret was in command of the French fleet at the battle of the First on June. He was a member of the Council of the Ancients in 1796, and was sentenced to deportation in 1797 on account of his royalist sympathies. He then lived in obscurity at Oléron. In 1801 he commanded the squadron which transported the French army to San Domingo, and in 1802 was made captain-general of Martinique, which he surrendered to the English in 1809. In 1811 he became governor-general of Venice.

VILLARI (vĭl'lahr-ĭ), **PASQUALE** (1827–1917), Italian historian and statesman, born at Naples Oct. 3, 1827, studied with Luigi la Vista under Francesco de Sanctis. Implicated in the riots of May 15, 1848, at Naples, against the Bourbon government, he took refuge in Florence where he published his *Storia di Girolamo Savonarola e de' suoi tempi* (2 vols. 1859–61). It was followed by a work of even greater critical value, *Niccolò Machiavelli e i suoi tempi* (1877–82). Both these works have been through many editions, the latest in 1927. Meanwhile Villari had been professor of history at Pisa, and now obtained the chair of philosophy of history at the Institute of Studii Superiori in Florence. He was also a member of the council of education (1862), and in 1869 was made under-secretary of state for education. In 1884 he was nominated senator, and in 1891–92 minister of education. His collected essays on Florentine history were published as *I primi due secoli della storia di Firenze* (1893–94), and in 1901 his *Le Invasioni barbariche in Italia*, a popular account of the events following the dissolution of the Roman empire. All these works have been translated into English by his wife. Villari died at Florence on Dec. 5, 1917. Villari's historical, political and social writings exercised a deep influence on his generation, and most of the Italian historians of to-day have been his pupils.

His other works include: *Saggi Critici* (1868); *Arte, Storia, e Filosofia* (Florence, 1884); *Scritti varii* (Bologna, 1894); another volume of *Saggi Critici* (Bologna, 1896); *Discussioni critiche e discorsi* (Bologna, 1905), containing his speeches as president of the Dante Alighieri Society; *Lettere Meridionali* containing the first exposure of conditions in south Italy (Turin, 1885), *Scritti sulla questione sociale in Italia* (Florence, 1902); *L'Italia da Carlo Magno alla Morte di Arrigo VII.* (Milan, 1910, Eng. trs. 1910) and *Storia, politica e istruzione* (Milan, 1914).

See F. Baldasseroni, *Pasquale Villari* (Florence, 1907).

VILLA RICA, the largest city in the interior of Paraguay, on the railway from Asuncion (70 m. N.W.) to Encarnacion. Pop. (1927) about 25,000. Situated in a rich agricultural region watered by the upper Tepicuary, with finely timbered mountains extending to the E. and W., Villa Rica has an important trade in tobacco, oranges and *yerba maté*. It is to a great extent primitive, but contains some attractive buildings, including a college, a church, schools and a branch of the Agricultural Bank.

VILLARREAL, a town of eastern Spain, in the province of Castellón de la Plana; 4 m. from the Mediterranean sea, near the right bank of the river Mijares, and on the Barcelona-Valencia railway. Pop. (1920) 16,770. Villarreal has a station on the light railway between Onda and the seaports of Castellón de la Plana and Burriana. Palm-groves, churches with blue-tiled cupolas, and houses with flat roofs and view-turrets (*miradores*) to some extent preserve the Moorish character of the town. Under Moorish rule, and up to the expulsion of the Moriscoes in 1609, it was the headquarters of a flourishing trade. There are extensive orange-groves, watered by the irrigation canal of Castellón, which is a good example of Moorish engineering skill. There are manufactures of paper, woollen goods and spirits.

VILLARS, CLAUDE LOUIS HECTOR DE, PRINCE DE MARTIGNES, MARQUIS AND DUC DE VILLARS AND VICOMTE DE MELUN (1653–1734), marshal of France, one of the greatest generals of French history, was born at Moulins on May 8, 1653, and entered the army through the corps of pages in 1671. He served in the light cavalry in the Dutch wars, and distinguished himself by his daring and resourcefulness. But in spite of a long record of excellent service under Turenne, Condé and Luxembourg, and of his aristocratic birth, his promotion was but slow, for he had incurred the enmity of the powerful Louvois, and although he had been proprietary colonel (*mestre de camp*) of a cavalry regiment since 1674, thirteen years elapsed before he was made a *maréchal de camp*. In the interval between the Dutch wars and the formation of the League of Augsburg, Villars was employed in an unofficial mission to the court of Bavaria, and there became the constant companion of the elector, with whom he took the field against the Turks and fought at Mohacs. He returned to France in 1690 and was given a command in the cavalry of the army in Flanders, but towards the end of the Grand Alliance War he went to Vienna as ambassador. His part in the next war (*see* SPANISH SUCCESSION, WAR OF THE), beginning with Friedlingen (1702) and Höchstett (1703) and ending with Denain (1712), has made him immortal. For Friedlingen he received the marshalate, for the pacification of the insurgent Cévennes the Saint-Esprit order and the title of duke. Friedlingen and Höchstett were barren victories, and the campaigns of which they formed a part, records of lost opportunities. Villars's glory thus begins with the year 1709 when France, apparently helpless, was roused to a great effort of self-defence by the exorbitant demands of the Coalition. In that year he was called to command the main army opposing Eugene and Marlborough on the northern frontier. During the famine of the winter he shared the soldiers' miserable rations. When the campaign opened the old Marshal Boufflers volunteered to serve under him, and after the terrible battle of Malplaquet (*q.v.*), in which he was gravely wounded, he was able to tell the king: "If it please God to give your majesty's enemies another such victory, they are ruined." Two more campaigns passed without a battle and with scarcely any advance on the part of the invaders, but at last Marlborough manoeuvred Villars out of the famous *Ne plus ultra* lines, and the power of the defence seemed to be broken. But Louis made

a last effort, the English contingent and its great leader were withdrawn from the enemy's camp, and Villars, though still suffering from his Malplaquet wounds, outmanoeuvred and decisively defeated Eugene in the battle of Denain. This victory saved France, though the war dragged on for another year on the Rhine, where Villars took Landau, led the stormers at Freiburg and negotiated the peace of Rastatt with Prince Eugene.

He played a conspicuous part in the politics of the Regency period as the principal opponent of Cardinal Dubois, and only the memories of Montmorency's rebellion prevented his being made constable of France. He took the field for the last time in the War of the Polish Succession (1734), with the title "marshal-general of the king's armies," that Turenne alone had held before him. But he was now over eighty years of age, and the war was more diplomatic than earnest, and after opening the campaign with all the fire and restless energy of his youth he died at Turin on June 17, 1734.

Villars' memoirs show us a "fanfaron plein d'honneur," as Voltaire calls him. He was indeed boastful, with the gasconading habit of his native province, and also covetous of honours and wealth. But he was an honourable man of high courage, moral and physical, and a soldier who stands above all his contemporaries and successors in the 18th century, on the same height as Marlborough and Frederick.

The memoirs, part of which was published in 1734 and afterwards several times republished in untrustworthy versions, were for the first time completely edited by the Marquis de Vogüé in 1884–92.

VILLARS (VILLARS-SUR-OLLON), a Swiss winter sports centre, frequented in summer also, situated at over 4,100ft. above sea-level, on a narrow gauge railway that branches from the Lausanne-Brig main line at Bex, about 8½m. beyond the point at which the railway leaves the Lake of Geneva. It is some distance above Gryon and commands a fine view of the Dent du Midi and the western Alps, and the Grand Muveran (3,061 metres) nearby. The railway runs on to Chesières, another resort which, in its turn, has road vehicles to Ollon, a station on the light railway from Monthey, which joins the Lausanne-Brig main line at Aigle.

VILLAVICIOSA, a seaport of northern Spain, in the province of Oviedo; on the Rio de Villaviciosa, an estuary formed by the small river Villaviciosa which here enters the Bay of Biscay. Pop. (1920) 20,712. The town is the headquarters of a large fishery, and has some coasting trade. Its exports are chiefly agricultural produce.

VILLEFRANCHE-DE-ROUERGUE, a town of France, capital of an *arrondissement* in the department of Aveyron, 36 m. W. of Rodez by road. Pop. (1926) 5,557. Villefranche, founded about 1252, owes its name to the numerous immunities granted by its founder Alphonse, count of Toulouse (d. 1271), and in 1348 it was so flourishing that sumptuary laws were passed. Soon afterwards the town fell into the hands of Edward, the Black Prince, but was the first place in Guienne to rise against the English. New privileges were granted to the town by King Charles V., but these were taken away by Louis XI. In 1588 the inhabitants repulsed the forces of the League. Villefranche, which has a station on the Orléans railway, lies amongst the hills on the right bank of the Aveyron at its junction with the Alzou. One of the three bridges that cross the river is of the 13th century, and there are many houses of the 13th and 14th centuries. The church of Notre Dame is flanked by a massive tower, beneath the porch of which passes one of the chief streets. The fine woodwork in the choir dates from the 15th century. The 15th and 16th century buildings (notably the fine refectory and two cloisters, the smaller a gem of late Gothic work) of a Carthusian monastery stand above the town on the left bank of the Aveyron. Quarries of phosphates and mines of galena and blende are worked near Villefranche. Villefranche is an agricultural centre with minor industries, and is the seat of a sub-prefect.

VILLEFRANCHE-SUR-SAÔNE, a manufacturing town of east-central France, capital of an *arrondissement* in the department of Rhone, on the Morgon near its junction with the Saône, 21 m. N. by W. of Lyons by rail. Pop. (1926) 16,427. Founded in 1212 by Guichard IV., count of Beaujeu, Villefranche became in the 14th century capital of the Beaujolais. Edward II. was forced to surrender the Beaujolais to the duke of Bourbon. Among its industries the chief are the manufacture of working clothes, the manufacture, dyeing and finishing of cotton fabrics, including surgical dressings, linings, the spinning of cotton thread, copper founding and the manufacture of machinery and agricultural implements. The wines of Beaujolais, hemp, cotton cloth, linen, cotton thread, drapery goods and cattle are the principal articles of trade. An old Renaissance house is used as the town hall. The 15th century church of Notre Dame des Marais, has a 16th century tower and spire (rebuilt in 1862), standing to the right of the façade. Villefranche is the seat of a sub-prefect and has a tribunal of commerce and a chamber of commerce.

VILLEHARDOUIN, GEOFFROY DE (*c.* 1160–*c.* 1213), the first vernacular historian of France, and perhaps of modern Europe, who possesses literary merit, is rather supposed than known to have been born at the château from which he took his name, near Troyes, in Champagne, about the year 1160. Not merely his literary and historical importance, but almost all that is known about him, comes from his chronicle of the fourth crusade, or *Conquête de Constantinople*. He was one of a list of knights of Champagne who with their count, Thibault, took the cross at a tournament held at Escry-sur-Aisne in Advent 1199. The next year six deputies, two appointed by each of the three allied counts of Flanders, Champagne and Blois, were despatched to Venice to negotiate for ships. Of these deputies Villehardouin was one and Quesnes de Béthune, the poet, another. They concluded a bargain with the seigniory for transport and provisions at a fixed price. Villehardouin had hardly returned when Thibault fell sick and died. Villehardouin made another embassy into Italy to prevent if possible some of his fellow-pilgrims from breaking the treaty with the Venetians by embarking at their ports and employing other convoy.

Villehardouin does not tell us of any direct part taken by himself in the debates on the question of interfering or not in the disputed succession to the empire of the East—debates in which the chief ecclesiastics present strongly protested against the diversion of the enterprise from its proper goal. It is quite clear, however, that the marshal of Champagne, who was one of the leaders and inner counsellors of the expedition throughout, sympathized with the majority, and it is fair to point out that the temptation of chivalrous adventure was probably as great as that of gain. He narrates spiritedly enough the dissensions and discussions in the winter camp of Zara and at Corfu, but is evidently much more at ease when the voyage was again resumed, and, after a fair passage round Greece, the crusaders at last saw before them the great city of Constantinople which they had in mind to attack.

When the assault was decided upon, Villehardouin himself was in the fifth "battle," the leader of which was Mathieu de Montmorency. But he does not tell us anything of his own prowess. After the flight of the usurper Alexius, and when the blind Isaac, whose claims the crusaders were defending, had been taken by the Greeks from prison and placed on the throne, Villehardouin, with Montmorency and two Venetians, formed the embassy sent to arrange terms. He was again similarly distinguished when it became necessary to remonstrate with Alexius, the blind man's son and virtual successor, on the non-keeping of the terms. Indeed Villehardouin's talents as a diplomatist seem to have been held in very high esteem, for later, when the Latin empire had become a fact, he was charged with the delicate business of mediating between the emperor Baldwin and Boniface, marquis of Montferrat, in which task he had at least partial success. He was also appointed marshal of "Romanie"—a term very vaguely used, but apparently signifying the mainland of the Balkan Peninsula, while his nephew and namesake, afterwards prince of Achaia, took a great part in the Latin conquest of Peloponnesus.

Villehardouin himself before long received an important command against the Bulgarians. He was left to maintain the siege of Adrianople when Baldwin advanced to attack the relieving force, and with Dandolo had much to do in saving the defeated crusaders from utter destruction, and in conducting the retreat, in

which he commanded the rearguard, and brought his troops in safety to the sea of Rodosto, and thence to the capital. As he occupied the post of honour in this disaster, so he had that (the command of the vanguard) in the expedition which the regent Henry made shortly afterwards to revenge his brother Baldwin's defeat and capture. And, when Henry had succeeded to the crown on the announcement of Baldwin's death, it was Villehardouin who fetched home his bride Agnes of Montferrat, and shortly afterwards commanded under him in a naval battle with the ships of Theodore Lascaris at the fortress of Cibotus. In the settlement of the Latin empire after the truce with Lascaris, Villehardouin received the fief of Messinople from Boniface of Montferrat, with the record of whose death the chronicle abruptly closes.

Villehardouin reappears for us once, but once only, in the chronicle of his continuator, Henri de Valenciennes. There is a great gap in style, though none in subject, between the really poetical prose of the first historian of the fifth crusade and the Latin empire and the awkward mannerism (so awkward that it has been taken to represent a "disrhymed" verse chronicle) of his follower. But the much greater length at which Villehardouin appears on this one occasion shows us the restraint which he must have exercised in the passages which deal with himself in his own work. He again led the vanguard in the emperor Henry's expedition against Burilas the Bulgarian, and he is represented by the Valenciennes scribe as encouraging his sovereign to the attack in a long speech. Then he disappears altogether, with the exception of some brief and chiefly diplomatic mentions. Du Cange discovered and quoted a deed of donation by him dated 1207, by which certain properties were devised to the churches of Notre Dame de Foissy and Notre Dame de Troyes, with the reservation of life interests to his daughters Alix and Damerones, and his sisters Emmeline and Haye, all of whom appear to have embraced a monastic life. A letter addressed from the East to Blanche of Champagne is cited, and a papal record of 1212 styles him still "marshal of Romania." The next year this title passed to his son Erard; and 1213 is accordingly given as the date of his death.

It would be out of place to attempt any further analysis of the *Conquête* here. But it is not impertinent, and is at the same time an excuse for what has been already said, to repeat that Villehardouin's book, brief as it is, is in reality one of the capital books of literature, not merely for its merit, but because it is the most authentic and the most striking embodiment in contemporary literature of the sentiments which determined the action of a great and important period of history. There are but very few books which hold this position, and Villehardouin's is one of them. If every other contemporary record of the crusades perished, we should still be able by aid of this to understand and realize what the mental attitude of crusaders, of Teutonic knights, and the rest was, and without this we should lack the earliest, the most undoubtedly genuine, and the most characteristic of all such records. The very inconsistency with which Villehardouin is chargeable, the absence of compunction with which he relates the changing of a sacred religious pilgrimage into something by no means unlike a mere filibustering raid on the great scale, add a charm.

The book appears to have been known in the ages immediately succeeding his own; and, though there is no contemporary manuscript in existence, there are some half-dozen which appear to date from the end of the 13th or the course of the 14th century, while one at least appears to be a copy made from his own work in that spirit of unintelligent faithfulness which is much more valuable to posterity than more pragmatical editing. The first printed edition of the book, by a certain Blaise de Vigenère, dates from 1585, is dedicated to the seigniory of Venice (Villehardouin, it should be said, has been accused of a rather unfair predilection for the Venetians), and speaks of either a part or the whole of the memoirs as having been printed twelve years earlier. Of this earlier copy nothing seems to be known. A better edition, founded on a Netherlandish ms., appeared at Lyons in 1601. But both these were completely antiquated by the great edition of Du Cange in 1657, wherein that learned writer employed all his knowledge, never since equalled, of the subject, but added a translation, or rather paraphrase, into modern French which is scarcely worthy either of himself or his author. Dom Brial gave a new edition from different ms. sources in 1823, and the book figures with different degrees of dependence on Du Cange and Brial in the collections of Petitot, Buchon, and Michaud and Poujoulat.

All these, however, have been superseded for the modern student by the editions of Natalis de Wailly (1872 and 1874), in which the text is critically edited from all the available mss. and a new translation added, while there is a still later and rather handier one by E. Bouchet (2 vols., Paris, 1891), which, however, rests mainly on N. de Wailly for text. The charm of Villehardouin can escape no reader; but few readers will fail to derive some additional pleasure from the two essays which Sainte-Beuve devoted to him, reprinted in the ninth volume of the *Causeries du lundi*. *See* also A. Debidour, *Les Chroniqueurs* (1888). There are English translations by T. Smith (1829), and (more literally) Sir F. T. Marzials (Everyman's Library, 1908).

VILLEINAGE (VILLAINAGE, VILLENAGE), a mediaeval term (from *villa, villanus*), pointing to serfdom, a condition of men intermediate between freedom and slavery. It occurs in France as well as in England, and was certainly imported into English speech through the medium of Norman French.

The materials for the formation of the villein class were already in existence in the Anglo-Saxon period. On the one hand, the Saxon ceorls (*twihyndemen*), although considered as including the typical freemen in the earlier laws (Aethelberht, Hlothhere and Edric, Ine), gradually became differentiated through the action of political and economic causes, and many of them had to recognize the patronage of magnates or to seek livelihood as tenants on the estates of the latter. These ceorls, sitting on gafolland, were, though personally free, considered as a lower order of men, and lapsed gradually into more or less oppressive subjection to the lords of whom they held their land. It is characteristic in this connection that the West Saxon laws do not make any distinction between ceorls and laets or half-freemen as the Kentish laws had done: this means that the half-free people were, if not Welshmen, reckoned as members of the ceorl class. Another remarkable indication of the decay of the ceorl's estate is afforded by the fact that in the treaties with the Danes the twihynde ceorls are equated with the Danish leysings or freedmen. It does not mean, of course, that their condition was practically the same, but in any case the fact testifies to the gulf which had come to separate the two principal subdivisions of the free class —the ceorl and the thegn. The Latin version of the *Rectitudines Singularum Personarum*, a document compiled probably in the 11th century, renders *geneat* (a peasant tenant of a superior kind performing lighter services than the gebur, who was burdened with heavy week-work) by *villanus;* but the gebur came to be also considered as a *villanus* according to Anglo-Norman terminology. The group designated as *geburs* in Anglo-Saxon charters, though distinguished from mere slaves, undoubtedly included many freedmen who in point of services and economic subjection were not very much above the slaves. Both ceorls and geburs disappear as separate classes, and it is clear that the greater part of them must have passed into the rank of villeins.

In the terminology of the Domesday Inquest we find the villeins as the most numerous element of the English population. Out of about 240,000 households enumerated in Domesday 100,000 are marked as belonging to villeins. They are rustics performing, as a rule, work services for their lords. But not all the inhabitants of the villages were designated by that name. Villeins are opposed to socmen and freemen on one hand, to *bordarii*, cottagers and slaves on the other. The distinction in regard to the first two of these groups was evidently derived from their greater freedom, although the difference is only one in degree and not in kind. In fact, the villein is assumed to be a person free by birth, but holding land of which he cannot dispose freely. The distinction as against *bordarii* and cottagers is based on the size of the holding: the villeins are holders of regular shares in the village —that is, of the virgates, bovates or half-hides which constitute the principal subdivisions in the fields and contribute to form the plough-teams—whereas the *bordarii* hold smaller plots of some five acres, more or less, and *cottarii* are connected with mere cottages and crofts. Thus the terminology of Domesday takes note of two kinds of differences in the status of rustics: a legal one in connection with the right to dispose of property in land, and an economic one reflecting the opposition between the holders of shares in the fields and the holders of auxiliary tenements. The feature of personal serfdom is also noticeable, but it provides a

basis only for the comparatively small group of *servi*, of whom only about 25,000 are enumerated in Domesday Book. The contrast between this exceptionally situated class and the rest of the population shows that personal slavery was rapidly disappearing in England about the time of the Conquest. It is also to be noticed that the Domesday Survey constantly mentions the *terra villanorum* as opposed to the lord's demesne, and that the land of the rustics is taxed separately for the geld, so that the distinction between the property of the lord and that of the peasant dependent on him is clearly marked.

The Domesday Survey puts before us the state of things in England as it was at the very beginning of the Norman and at the close of the Saxon period. The development of feudal society, of centralizing kingship and ultimately of a system of common law, brought about great changes which all hinge on the fundamental fact that the kings, while increasing the power of the State in other respects, surrendered it completely as regards the relations between the peasants and their lords. The protection of the assizes was tendered in civil matters to free tenants and refused to villeins. The royal courts refused to entertain suits of villeins against their lords, although there was a good deal of vacillation before this position was definitely taken up. Bracton speaks in his treatise of the possibility of interference by the courts against intolerable cruelty on the part of the lord involving the destruction of the villein's waynage, that is, of his tillage, and in the *Notebook* of Bracton may be found a couple of cases which prove that 13th century judges occasionally allowed themselves to entertain actions by persons holding in villeinage against their lords. Gradually, however, the exception of villeinage became firmly settled. As the historical and practical position was developing on these lines the lawyers who fashioned English common law in the 12th and 13th centuries did not hesitate to apply to it the teaching of Roman law on slavery. Bracton fits his definition of villeinage into the Romanesque scheme of Azo's *Summa* of the Institutes, and the judges of the royal courts made sweeping inferences from this general position. To begin with, the relation between the villein and his lord was regarded as a personal and not a praedial one. Everyone born of villein stock belonged to his master and was bound to undertake any service which might be imposed on him by the master's or the steward's command. The distinction between villeins in gross and villeins regardant, of which much is made by modern writers, was suggested by modes of pleading and does not make its appearance in the Year-Books before the 15th century. Secondly, all independent proprietary rights were denied to the villein as against his lord, and the legal rule "quicquid servo acquiritur domino acquiritur" was extended to villeins. The fact that a great number of these serfs had been enjoying protection as free ceorls in former ages made itself felt, however, in three directions. (1) In criminal matters the villein was treated by the King's Court irrespectively of any consideration as to his debased condition. More especially the police association, organized for the keeping of the peace and the presentation of criminals—the frankpledge groups—were formed of all "worthy of were and wite," villeins as well as freemen. (2) Politically the villeins were not eliminated from the body of citizens; they had to pay taxes, to serve in great emergencies in the militia, to serve on inquests, etc., and although there was a tendency to place them on a lower footing in all these respects yet the fact of their being lesser members of the commonwealth did not remove the fundamental qualification of citizenship. (3) Even in civil matters villeins were deemed free as regards third persons. They could sue and be sued in their own name, and although they were able to call in their lords as defendants when proceeded against, there was nothing in law to prevent them from appearing in their own right. The state even afforded them protection against extreme cruelty on the part of their masters in respect of life and limb, but in laying down this rule English lawyers were able to follow the precedents set by late Roman jurisprudence, especially by measures of Hadrian, Antonine and Constantine the Great.

There was one exception to this harsh treatment of villeins. The rustic tenantry in manors of *ancient demesne*, that is, in estates which had belonged to the crown before the Conquest, had a standing-ground even against their lords as regards the tenure of their plots and the fixity of their services. Technically this right was limited to the inhabitants of manors entered in the Domesday Survey as *terra regis* of Edward the Confessor. On the other hand the doctrine became effective if the manors in question had been granted by later kings to subjects, because if they remained in the hand of the king the only remedy against ejectment and exaction lay in petitioning for redress without any definite right to the latter. If, however, the two conditions mentioned were forthcoming, villeins, or, as they were technically called, villein socmen of ancient demesne manors, could resist any attempt of their lords to encroach on their rights by depriving them of their holdings or increasing the amount of their customary services. Their remedy was to apply for a little writ of right in the first case and for a writ of *monstraverunt* in the second. These writs entitled them to appear as plaintiffs against the lord in his own manorial court and, eventually, to have the question at issue examined by way of appeal, on a writ of error, or by reservation on some legal points in the upper courts of the king. A number of cases arising from these privileges of the men of ancient demesne are published in the *Notebook* of Bracton and in the *Abbreviatio placitorum*. This exceptional procedure does not simply go back to the rule that persons who had been tenants of the king ought not to have their condition altered for the worse in consequence of a royal grant. If this were the only doctrine applicable in the case there would be no reason why similar protection should be denied to all those who held under grantees of manors escheated after the Conquest. A material point for the application of the privilege consists in the fact that ancient demesne has to be proved from the time before the Conquest, and this shows clearly that the theory was partly derived from the recognition of tenant right in villeins of the Anglo-Saxon period who, as we have said above, were mostly ceorls, that is, freeborn men.

In view of the great difference in the legal position of the free man and of the villein in feudal common law, it became very important to define the exact nature of the conditions on which the status of a villein depended. The legal theory as to these conditions was somewhat complex. Of course, persons born from villein parents in lawful wedlock were villeins, but as to the condition of illegitimate children there was a good deal of hesitation. There was a tendency to apply the rule that a bastard follows the mother, especially in the case of a servile mother. In the case of mixed marriages, the condition of the child was determined by the free or villein condition of the tenement in which it was born. This notion of the influence of the tenement is in accord with feudal ideas and makes itself felt again in the case of the pursuit of a fugitive villein. He can be seized without further formalities if he is caught in his "nest," that is, in his native place. If not, the lord can follow him in fresh pursuit for four days; once these days are past, the fugitive is maintained provisionally in possession of his liberty, and the lord has to bring an action *de nativo habendo* and has to assume the burden of proof.

So much as to the proof of villeinage by birth or previous condition. But there were numbers of cases when the discussion as to servile status turned not on these formal points but on an examination of the services performed by the person claimed as a villein or challenged as holding in villeinage. In both cases the courts had often recourse to proof derived not from direct testimony but from indirect indications as to the kind of services that had been performed by the supposed villein. Certain services, especially the payment of *merchet*—the fine for marrying a daughter—were considered to be the badge of serfdom. Another service, the performance of which established a presumption as to villeinage, was compulsory service as a reeve. The courts also tried to draw a distinction from the amount and regularity of agricultural services to which a tenant was subjected. Bracton speaks of the contrast between the irregular services of a serf, "who could not know in the evening what he would have to do in the morning," and services agreed upon and definite in their amount. The customary arrangements of the work of villeins,

however, render this contrast rather fictitious. The obligations of downright villeins became so far settled and regular that one of the ordinary designations of the class was *custumarii*. Therefore in most cases there were no arbitrary exactions to go by, except perhaps one or the other tallage imposed at the will of the lord. The original distinction seems to have been made not between arbitrary and agreed but between occasional services and regular agricultural week-work. While the occasional services, even when agricultural, in no way established a presumption of villeinage, and many socmen, freemen and holders by serjeanty submitted to them, agricultural week-work was primarily considered as a trait of villeinage and must have played an important part in the process of classification of early Norman society.

This point brings us to consider the matter-of-fact conditions of the villeins during the feudal period, especially in the 12th, 13th and 14th centuries. As is shown by the Hundred Rolls and countless other records of the same kind, the customary conditions of villeinage did not tally by any means with the identification of villeinage with slavery suggested by the jurists. It is true that in nomenclature the word *servi* is not infrequently used (*e.g.*, in the Hundred Rolls) where *villani* might have been mentioned, and the feminine *nief* (*nativa*) appears as the regular parallel to *villanus*, but in the descriptions of usages and services we find that the power of the lord loses its discretionary character and is in every respect moderated by custom. As personal dependents of the lord native villeins were liable to be sold, and we find actual sales recorded: Glastonbury Abbey, *e.g.*, sells a certain Philipp Hardyng for 20 shillings. But such transfers of human chattels occur seldom, and there is nothing during the English feudal period corresponding to the brisk trade in men characteristic of the ancient world. *Merchet* was regarded as a badge of serfdom in so far as it was said to imply a "buying of one's own blood" (*servus de sanguine suo emendo*). The explanation is even more characteristic than the custom itself, because fines on marriage might be levied and were actually levied on people of different condition, on the free as well as on the serf. Still the tendency to treat *merchet* as a distinctive feature of serfdom has to be noted, and we find that the custom spread for this very reason in consequence of the encroachments of powerful lords; in the Hundred Rolls it is applied indiscriminately to the whole rustic population of certain hundreds in a way which can hardly be explained unless by artificial extension. *Heriot*, the surrender of the best horse or ox, is also regarded as the common incident of villein tenure, although, of course, its very name proves its intimate connection with the outfit of soldiers (*here-geatu*).

Economically the institution of villeinage was bound up with the manorial organization—that is, with the fact that the country was divided into a number of districts in which central home farms were cultivated by work supplied by villein households.

The most important of villein services is the *week-work* performed by the peasantry. Every virgater or holder of a bovate has to send a labourer to do work on the lord's farm for some days in the week. Three days is indeed the most common standard for service of this kind, though four or even five occur sometimes, as well as two. It must be borne in mind in the case of heavy charges, such as four or five days' week-work, that only one labourer from the whole holding is meant, while generally there were several men living on every holding—otherwise the service of five days would be impossible to perform. In the course of these three days, or whatever the number was, many requirements of the demesne had to be met. The principal of these was *ploughing the fields* belonging to the lord, and for such ploughing the peasant had not only to appear personally as a labourer, but to bring his oxen and plough, or rather to join with his oxen and plough in the work imposed on the village; the heavy, costly plough with a team of eight oxen had to be made up by several peasants contributing their beasts and implements towards its composition. In the same way the villagers had to go through the work of harrowing with their harrows, and of removing the harvest in their vans and carts. *Carriage* duties in carts and on horseback were also apportioned according to the time they took as a part of the week-work. Then came innumerable varieties of manual work for the making and keeping up of hedges, the preservation of dykes, canals and ditches, the threshing and garnering of corn, the tending and shearing of sheep, and so forth. All this hand-work was reckoned according to customary standards as day-work and week-work. But besides all these services into which the regular week-work of the peasantry was differentiated, there were some additional duties. The ploughing for the lord, for instance, was not only imposed in the shape of a certain number of days in the week, but took sometimes the shape of a certain number of acres which the village had to plough and to sow for the lord irrespectively of the time employed. This was sometimes termed *gafolearth*. Exceedingly burdensome services were required in the seasons when farming processes are at their height—in the seasons of mowing and reaping, when every day is of special value and the working power of the farm hands is strained to the utmost. At those times it was the custom to call up the whole able-bodied population of the manor, with the exception of the housewives, for two, three or more days of mowing and reaping on the lord's fields; to these *boon-works* the peasantry was asked or invited by special summons, and their value was so far appreciated that the villagers were usually treated to meals in cases where they were again and again called off from their own fields to the demesne. The liberality of the lord actually went so far, in exceptionally hard straits, that ale was served to the labourers.

By the 14th century this social arrangement, based primarily on natural economy, had given way; the time of *commercial, contractual, cash intercourse* was fast approaching.

If we now turn to the actual stages by which this momentous passage from the manorial to the commercial arrangement was achieved, we have to notice first of all a rapid *development of contractual relations*. We know that in feudal law there was a standing contrast between *tenure by custom*—villein tenure—and *tenure by contract*—free tenure. While the manorial system was in full force this contrast led to a classification of holdings and affected the whole position of people on the land. Still, even at that time it might happen that a freeholder owned some land in villeinage by the side of his free tenement, and that a villein held some land freely by agreement with his lord or with a third person. But these cases, though by no means infrequent, were still exceptional. As a rule people used land as holdings, and those were rigidly classified as villein or free tenements. The interesting point is that, without any formal break, *leasing land for life and for terms of years* is seen to be rapidly spreading during the 13th century, and many small tenancies are created which break up the disposition of the holdings. From the close of the 13th century countless transactions on the basis of leases for terms of years occur between the peasants themselves. Any suitably kept set of 14th century court rolls contains entries in which such and such a villein is said to appear in the *halimote* and to surrender for the use of another person named a piece of land belonging to the holding. The number of years and the conditions of payment are specified. Thus, behind the screen of the normal shares a number of small tenancies arise which run their economic concerns in independence of the cumbersome arrangements of tenure and service, and, needless to add, all these tenancies are burdened with money rents.

Another series of momentous changes took place in the *arrangement of services*. Even the manorial system admitted the buying off for money of particular dues in kind and of specific performance of work. A villein might be allowed to bring a penny instead of a chicken, or to pay a rent instead of appearing with his oxen three times a week on the lord's fields. Such rents were called *mal* or *mail* in contrast with the *gafol*, ancient rents which had been imposed independently, apart from any buying off of customary services. There were even whole bodies of peasants called *Molmen*, because they had bought off work from the lord by settling with him on the basis of money rents. As time went on these practices of *commutation* became more and more frequent. There were, for both sides, many advantages in arranging their mutual relations on this basis. The lord got clear money—a much-coveted means of satisfying needs and wishes of any kind—instead of

cumbrous performances which did not come always at the proper moment, were carried out in a half-hearted manner, yielded no immediate results, and did not admit of convenient rearrangement. The peasant got rid of a hateful drudgery which not only took up his time and means in an unprofitable manner, but placed him under the arbitrary control of stewards or reeves and gave occasion to all sorts of fines and extortions.

With the growth of intercourse and security money circulated more freely and the number of such transactions increased in proportion. But it must be kept in mind that the conversion of services into rents went on very gradually, as a series of private agreements, and that it would be wrong to suppose, as some scholars have done, that it had led to a general commutation by the middle or even the end of the 14th century. The 14th century was marked by violent fluctuations in the demand and supply of labour, and particularly the tremendous loss in population caused in the middle of this century by the Black Death produced a most serious crisis. No wonder that many lords clung very tenaciously to customary services, and ecclesiastical institutions seem to have been especially backward in going over to the system of money rents. There is evidence to show, for instance, that the manors of the abbey of Ramsey were managed on the system of enforced labour right down to the middle of the 15th century, and, of course, survivals of these customs in the shape of scattered services lived on much longer. A second drawback from the point of view of the landlords was that commutation for fixed rents gradually lessened the value of the exactions to which they were entitled. Money not only became less scarce but it became cheaper, so that the couple of pence for which a day of manual work was bought off in the beginning of the 13th century did not fetch more than half of their former value at its end. As quit rents were customary and not rack rents, the successors of those who had redeemed their services were gaining the whole surplus in the value of goods and labour as against money, while the successors of those who had commuted their right to claim services for certain sums in money lost all the corresponding difference. These inevitable consequences came to be perceived in course of time and occasioned a tendency to revert to services in kind which could not prevail against the general movement from natural economy to money dealings, but was strong enough to produce social friction.

The economic crisis of the 14th century has its complement in the legal crisis of the 15th. At that time the courts of law began to do away with the denial of protection to villeins which, as we have seen, constituted the legal basis of villeinage. This is effected by the recognition of copyhold tenure (*see* COPYHOLD).

It is a fact of first-rate importance that in the 15th century customary relations on the one hand, and the power of government on the other, reached a stage of development at which the judges of the king began to take cognizance of the relations of the peasants to their lords. The first cases which occur in this sense are still treated not as a matter of common law, but as a manifestation of equity. As doubtful questions of trust, of wardship, of testamentary succession, they were taken up not in the strict course of justice, but as matters in which redress was sorely needed and could only be given by the exceptional power of the court of chancery. But this interference of 15th century chancellors paved the way towards one of the greatest revolutions in the law; without formally enfranchising villeins and villein tenure they created a legal basis for it in the law of the realm. In the formula of copyhold—*tenement held at the will of the lord and by the custom of the manor*—the first part lost its significance and the second prevailed, in downright contrast with former times when, on the contrary, the second part had no legal value and the first expressed the view of the courts. One may almost be tempted to say that these obscure decisions rendered unnecessary in England the work achieved with such a flourish of trumpets in France by the emancipating decree of Aug. 4, 1789.

The personal condition of villeinage did not, however, disappear at once with the rise of copyhold. It lingered through the 16th century and appears exceptionally even in the 17th. Deeds of emancipation and payments for personal enfranchisement are often noticed at that time. But these are only survivals of an arrangement which has been destroyed in its essence by a complete change of economic and political conditions.

VILLÈLE, JEAN BAPTISTE GUILLAUME MARIE ANNE SÉRAPHIN, COMTE DE (1773–1854), French statesman, was born at Toulouse on April 14, 1773 and educated for the navy. He joined the "Bayonnaise" at Brest in July 1788 and served in the West and East Indies. Arrested in the Isle of Bourbon under the Terror, he was set free by the revolution of Thermidor (July 1794). He acquired some property in the island, and married in 1799 the daughter of a great proprietor, M. Desbassyns de Richemont, whose estates he had managed. The arrival of General Decaen, sent out by Bonaparte in 1802, restored security to the island, and five years later Villèle, who had now realized a large fortune, returned to France. He was mayor of his commune, and a member of the council of the Haute-Garonne under the Empire. At the restoration of 1814 he at once declared for royalist principles. He was mayor of Toulouse in 1814–15 and deputy for the Haute-Garonne in the "Chambre Introuvable" of 1815. Villèle, who before the promulgation of the charter had written some *Observations sur le projet de constitution* opposing it, as too democratic in character, naturally took his place on the extreme right with the ultra-royalists. In the new Chamber of 1816 Villèle found his party in a minority, but his personal authority nevertheless increased. He was looked on by the ministerialists as the least unreasonable of his party, and by the "ultras" as the safest of their leaders. Under the electoral law of 1817 the Abbé Grégoire, who was popularly supposed to have voted for the death of Louis XVI. in the Convention, was admitted to the Chamber of Deputies. The Conservative party gained strength from the alarm raised by this incident and still more from the shock caused by the assassination of the duc de Berri. The duc de Richelieu was compelled to admit to the cabinet two of the chiefs of the Left, Villèle and Corbière. Villèle resigned within a year, but on the fall of Richelieu at the end of 1821 he became the real chief of the new cabinet, in which he was minister of finance. Although not himself a courtier, he was backed at court by Sosthènes de la Rochefoucauld and Madame du Cayla, and in 1822 Louis XVIII. gave him the title of count and made him formally prime minister.

He immediately proceeded to muzzle opposition by stringent press laws, and the discovery of minor Liberal conspiracies afforded an excuse for further repression. Forced against his will into interference in Spain, he reaped some credit from the campaign of 1823. Meanwhile he had persuaded Louis XVIII. to swamp the Liberal majority in the upper house by the nomination of twenty-seven new peers; he availed himself of the temporary popularity of the monarchy after the Spanish campaign to summon a new Chamber of Deputies. This new and obedient legislature, to which only nineteen Liberals were returned, made itself into a septennial parliament, thus providing time, it was thought, to restore some part of the *ancien régime*. Villèle's plans were assisted by the death of Louis XVIII. and the accession of his bigoted brother. Prudent financial administration since 1815 had made possible the conversion of the state bonds from 5 to 4%. It was proposed to utilize the money set free by this operation to indemnify by a milliard francs the *émigrés* for the loss of their lands at the Revolution; it was also proposed to restore their former privileges to the religious congregations. Both these propositions were, with some restrictions, secured. Sacrilege was made a crime punishable by death, and the ministry were preparing a law to alter the law of equal inheritance, and thus create anew the great estates. These measures roused violent opposition in the country, which a new and stringent press law, nick-

named the "law of justice and love," failed to put down. The peers rejected the law of inheritance and the press law; it was found necessary to disband the National Guard; and in November 1827 seventy-six new peers were created, and recourse was had to a general election. The new Chamber proved hostile to Villèle, who resigned to make way for the short-lived moderate ministry of Martignac.

The new ministry made Villèle's removal to the upper house a condition of taking office, and he took no further part in public affairs. At the time of his death, on March 13, 1854, he had advanced as far as 1816 with his memoirs, which were completed from his correspondence by his family as *Mémoires et correspondance du comte de Villèle* (Paris, 5 vols., 1887–90).

See also C. de Mazade, *L'Opposition royaliste* (Paris, 1894); J. G. Hyde de Neuville, *Notice sur le comte de Villèle* (Paris, 1899); and M. Chotard, "L'Oeuvre financière de M. de Villèle," in *Annales des sciences politiques* (vol. v., 1890).

VILLENA, ENRIQUE DE (1384–1433), Spanish author, sometimes wrongly called marqués de Villena. About 1402 he married Maria de Castilla, who speedily became the recognized mistress of Henry III.; the complaisant husband was rewarded by being appointed master of the military order of Calatrava in 1404, but the nomination was rescinded in 1415. Villena is represented by a fragment of his *Arte de trobar* (1414), an indigestible treatise composed for the Barcelona Consistory of Gay Science; by *Los Trabajos de Hércules* (1417), a pedantic and unreadable allegory; by his *Tratado de la Consolación* and his handbook to the pleasures and fashions of the table, the *Arte cisoria*, both written in 1423; by the *Libro de Aojamiento* (1425), a ponderous dissertation on the evil eye and its effects; and by a translation of the *Aeneid*, the first ever made (1428). His treatise on leprosy exists but has not been published. Villena's writings do not justify his extraordinary fame; his subjects are devoid of charm, and his style is so uncouth as to be almost unintelligible. Yet he has an assured place in the history of Spanish literature; he was a generous patron of letters and his translation of Virgil marks him out as a pioneer of the Renaissance.

VILLENA, a town of eastern Spain, in the province of Alicante; on the right bank of the river Vinalapó, and at the junction of railways from Valencia, Alicante, Albacete and Yecla. Pop. (1920) 16,544. Villena contains some interesting examples of Moorish domestic architecture. It is dominated by a Moorish castle. The surrounding hills are covered with vines, and to the east there is an extensive salt lagoon. Silk, linen, flour, wine, brandy, oil, salt and soap are the chief industrial products.

VILLENEUVE, PIERRE CHARLES JEAN BAPTISTE SILVESTRE (1763–1806), French admiral, was born at Valensoles (Provence) on Dec. 31, 1763. He entered the French royal navy as a "garde du Pavillon," and received rapid promotion, being named post-captain in 1793, and rear-admiral in 1796. At the close of the year he took part in the unsuccessful expedition to Ireland.

He accompanied the expedition to Egypt, with his flag in the "Guillaume Tell" (86). She was the third ship from the rear of the French line at the battle of the Nile, and escaped in company with the "Généreux" (78). Villeneuve reached Malta on Aug. 23. His conduct was severely blamed, and he defended himself by a specious letter to his colleague Blanquet-Duchayla on Nov. 12, 1800, from Paris. In a letter written to him on Aug. 21, 1798, Napoleon says that the only thing with which Villeneuve had to reproach himself was that he had not retreated sooner, since the position taken by the French commander-in-chief had been forced and surrounded. But, in dictating his account of the expedition to Egypt to General Bertrand at St. Helena, the ex-emperor attributed the defeat at the Nile largely to the "bad conduct of Admiral Villeneuve." Villeneuve failed in the execution of the scheme for the invasion of England in 1805.

Nevertheless, Napoleon selected him to succeed Latouche Tréville at Toulon on his death in August 1804. The duty of the Toulon squadron was to draw Nelson to the West Indies, return rapidly, and in combination with other French and Spanish ships, to enter the Channel with an overwhelming force. It is quite obvious that Villeneuve had from the first no confidence in the success of the operation. He knew that the French were not efficient, and that their Spanish allies were in a far worse state than themselves. It required a very tart order from Napoleon to drive him out of Paris in October 1804. He took the command in November. For the details of the campaign *see* TRAFALGAR. Having undertaken to carry out a plan of which he disapproved, it was clearly his duty to execute the orders he received. But Villeneuve could not free himself from the conviction that it was his business to save his fleet even if he ruined the emperor's plan of invasion. Thus after he returned to Europe and fought his confused action with Sir R. Calder off Ferrol on July 22, 1805, he first hesitated, and then, in spite of vehement orders to come on, turned south to Cadiz.

His decision to leave Cadiz and give battle in October 1805, which led directly to the battle of Trafalgar, cannot be justified even on his own principles. He foresaw defeat to be inevitable, and yet he went out solely because he learnt from the Minister of Marine that another officer had been sent to supersede him. At Trafalgar he showed personal courage, but the helpless incapacity of the allies to manoeuvre gave him no opportunity to influence the course of the battle. He was taken as a prisoner to England, but was soon released. He committed suicide at Rennes, on April 22, 1806.

The correspondence of Napoleon contains many references to Villeneuve. Accounts of the naval operations in which he was concerned will be found in James's *Naval History*. Troude, in his *Batailles navales de la France*, vol. iii., publishes several of his letters and orders of the day.

VILLENEUVE-LÈS-AVIGNON, a town of south-eastern France, in the department of Gard on the right bank of the Rhône opposite Avignon. Pop. (1926) 2,618. In the 6th century the Benedictine abbey of St. André was founded on Mont Andaon, and the village which grew up round it took its name. In the 13th century the monks, acting in concert with the crown, established a *bastide*, or "new town," which came to be called Villeneuve. The town was the resort of the French cardinals during the sojourn of the popes at Avignon, and was important till the Revolution.

Villeneuve preserves many remains of its mediaeval importance. The hospice, once a Franciscan convent, and the church and other remains of the Carthusian monastery of Val-de-Bénédiction, founded in 1356 by Innocent VI., are notable. A 17th century gateway and a rotunda, built as shelter for a fountain, are interesting. On the Mont Andaon, a hill to the north-east of the town, stands the fort of St. André (14th century), with a fortified entrance gateway and a Romanesque chapel and remains of the abbey of St. André.

VILLENEUVE-SUR-LOT, a town of south-western France, capital of an *arrondissement* in the department of Lot-et-Garonne, 22 m. N. by E. of Agen on a branch line of the Orléans railway. Pop. (1926) 7,174. Villeneuve was founded in 1254 by Alphonse, count of Poitiers, brother of Louis IX., on the site of the town of Gajac, which had been deserted during the Albigensian crusade.

The river Lot divides the town into two parts. The chief quarter stands on the right bank and is united to that on the left bank by a 13th century bridge. On the left bank portions of the 13th century ramparts, altered and surmounted by machicolations in the 15th century, remain, and high square towers rise above the gates to the north-east, the Porte de Paris, and south-west, the Porte de Pujols. Arcades of the 13th century surround the Place La Fayette, and there are old houses of the 13th, 14th and 15th centuries in various parts of the town. On the left bank of the Lot, 2 m. S.S.W. of Villeneuve, are the 13th-century walls of Pujols. The buildings of the ancient abbey of Eysses, about a mile to the N.E., mainly 17th century, remain. Villeneuve has a sub-prefecture and a tribunal of commerce. It is an important agricultural centre and has a very large trade in plums (*prunes d'ente*) and in the produce of the market gardens which surround it, as well as in cattle, horses and wine. The preparation of preserved plums and the tinning of peas and beans occupy many hands; there are also manufactures of shoes and tin boxes.

VILLEROI, FRANÇOIS DE NEUFVILLE, DUC DE (1644–1730), French soldier, was the son of Nicolas de Neufville, Marquis de Villeroi, marshal of France (1598–1685). His father, created a duke by Louis XIV., was the young king's governor, and the boy was thus brought up in close relations with Louis. An intimate of the king, a finished courtier and a man of great gallantry, Villeroi was marked out for advancement in the army and in 1693 was made a marshal. In 1695, when Luxembourg died, he obtained the command of the army in Flanders, and William III. found him a far more complaisant opponent than the "little hunchback." In 1701 he superseded Catinat in Italy and was soon beaten by Eugene at Chiari. (*See* SPANISH SUCCESSION WAR.) In the winter of 1701 he was made prisoner at Cremona, and the wits of the army made at his expense the famous rhyme:

> Par la faveur de Bellone, et par un bonheur san égal.
> Nous avons conservé Crémone—et perdu notre général.

In the following years he was pitted against Marlborough in the Low Countries, and in 1706 the duke defeated him at Ramillies (*q.v.*). Louis superseded him in the command, and henceforward Villeroi lived the life of a courtier. He died on July 18, 1730 at Paris.

VILLERS LA VILLE, a village of Belgium in the province of Brabant, 2 m. E. of Quatre Bras, with a station on the direct line from Louvain to Charleroi. Pop. (1920) 1,059. It is chiefly interesting on account of the fine ruins of the Cistercian abbey of Villers founded in 1147 and destroyed by the French in 1795.

VILLIERS, BARBARA: *see* CLEVELAND, DUCHESS OF.

VILLIERS DE L'ISLE-ADAM, PHILIPPE AUGUSTE MATHIAS, COMTE DE (1838–1889), French poet, was born at St. Brieuc in Brittany and baptized on Nov. 28, 1838. He may be said to have inaugurated the Symbolist movement in French literature, and *Axël,* the play on which he was engaged during so much of his life, though it was only published after his death, is the typical Symbolist drama. He began with a volume of *Premières Poésies* (1856–58). This was followed by a wild romance of the supernatural, *Isis* (1862), and by two plays in prose, *Elën* (1866) and *Morgane* (1866). *La Révolte,* a play in which Ibsen's *Doll's House* seems to be anticipated, was represented at the Vaudeville in 1870; *Contes cruels,* his finest volume of short stories, in 1883, and a new series in 1889; *Le Nouveau Monde,* a drama in five acts, in 1880; *L'Ève future,* an amazing piece of buffoonery satirizing the pretensions of science, in 1886; *Tribulat Bonhomet* in 1887; *Le Secret de l'échafaud* in 1888; *Axël* in 1890. He died in Paris, under the care of the Frères Saint-Jean-de-Dieu, on the 19th of August 1889.

Villiers has left behind him a legend probably not more fantastic than the truth. Sharing many of the opinions of Don Quixote, he shared also Don Quixote's life. He was the descendant of the Grand Master of the Knights of Malta, famous in history, and his pride as an aristocrat and as an idealist were equal. He hated mediocrity, science, progress, the present age, money and "serious" people.

He remains a remarkable poet and a remarkable satirist, imperfect as both. He improvised out of an abundant genius, but the greater part of his work was no more than improvisation. He was accustomed to talk his stories before he wrote them. Sometimes he talked them instead of writing them. But he has left, at all events, the *Contes cruels,* in which may be found every classic quality of the French *conte,* together with many of the qualities of Edgar Allan Poe and Ernst Hoffman; and the drama of *Axël,* in which the stage takes a new splendour and a new subtlety of meaning. Villiers's influence on the younger French writers was considerable. It was always an exaltation. No one in his time followed a literary ideal more romantically. (A. SY.)

See also R. du Pontavice de Heussey, *Villiers de l'Isle-Adam* (1893), a biography, English trans. (1904) by Lady Mary Loyd; S. Mallarmé, *Les Miens. Villiers de l'Isle-Adam* (1892); R. Martineau, *Un vivant et deux morts* (1901), bibliography. A selection from his stories, *Histoires souveraines,* was made by his friends (Brussels, 1899); there is a translation of the *Contes cruels* by Hamish Miles (*Sardonic Tales,* 1927).

VILLON, FRANÇOIS (1431–*c.* 1463), French poet, was born in 1431, and, as it seems, certainly at Paris. He was entered on the books of the university of Paris as François de Montcorbier, but was always known by the name of his patron, Guillaume de Villon. It appears that he was born of poor folk, that his father died in his youth, but that his mother, for whom he wrote one of his most famous *ballades,* was alive when her son was thirty years old. Villon was received into the house of Guillaume de Villon, chaplain in the collegiate church of Saint-Benoît-le-Bestourné, and a professor of canon law, who was probably a relative. The poet became a student in arts, no doubt early and took the degree of bachelor in 1449 and that of master in 1452.

On June 5, 1455, being in the company of a priest named Giles and a girl named Isabeau, he met, in the rue Saint-Jacques, a certain Breton, Jean le Hardi, a master of arts, who was with a priest, Philippe Chermoye or Sermoise or Sermaise. A scuffle ensued; daggers were drawn; and Sermaise, who started the broil, died of his wounds. Villon fled, and was sentenced to banishment—a sentence which was remitted in January 1456, the formal pardon being extant in two different documents, in one of which the culprit is described as "François des Loges, autrement dit Villon," in the other as "François de Montcorbier." By the end of 1456 he was again in trouble. In his first broil "la femme Isabeau" is only generally named, and it is impossible to say whether she had anything to do with the quarrel. In the second, Catherine de Vaucelles, of whom we hear not a little in the poems, is the declared cause of a scuffle in which Villon was so severely beaten that, to escape ridicule, he decided to flee to Angers, where he had an uncle who was a monk. As he was preparing to leave Paris he composed the *Petit Testament.* Hitherto Villon had been rather injured than guilty. But on the eve of leaving Paris he was concerned, just before Christmas 1456, in robbing the chapel of the college of Navarre from which five hundred gold crowns were stolen. The robbery was not discovered till March 1457, and in May the police came on the track of a gang of student-robbers owing to the indiscretion of one of them, Guy Tabarie. A year more passed, when Tabarie, being arrested, turned king's evidence and accused Villon, who was then absent, of being the ringleader, and of having gone to Angers, partly at least, to arrange for similar burglaries there. Villon, for this or some other crime, was sentenced to banishment: and he did not attempt to return to Paris. For four years he was a wanderer, apparently a pedlar for some part of the time; and he may have been, as each of his friends Regnier de Montigny and Colin des Cayeux certainly was, a member of a wandering thieves' gang. It is certain that at one time (in the winter of 1457), and probable that at more times than one, he was in correspondence with Charles d'Orléans, and visited that prince's court at Blois. He made his way to Bourges where he was again in trouble, and had a taste of prison. From Bourges he went to the Bourbonnais, where he found shelter for a brief period with Jean II. de Bourbon. Thence, if his own words are to be taken literally, he wandered to Dauphiné. He was in prison at Orleans, put to the question and under sentence of death, when he was released on the passage of the little princess of Orleans through the town on July 17, 1460. He had spent the summer of 1461 in the bishop's prison of Meung. Villon owed his release to Louis XI., who passed through Meung on a royal progress and freed prisoners on Oct. 2.

It was now that he wrote the *Grand Testament,* the work which has immortalized him. Although he was only thirty nothing appears to be left him but regret; his very spirit has been worn out by excesses or sufferings or both. In the autumn of 1462 we find him once more living in the cloisters of Saint-Benoît, and in November he was in the Châtelet for theft. In default of evidence the old charge of the college of Navarre was revived, and even a royal pardon did not bar the demand for restitution. Bail was, however, accepted, but Villon was present at a street quarrel from which he hastily got away. Nevertheless he was arrested, tortured and condemned to be hanged, but the sentence was commuted to banishment (for ten years) by the parlement on Jan. 5, 1463. From this time he disappears from history.

Villon's two *Testaments* are made up of eight-line stanzas of

eight-syllabled verses, varied in the case of the *Grand Testament* by the insertion of ballades and rondeaux. The sense of the vanity of human life pervades the whole of Villon's poetry. It is the very keynote of his most famous and beautiful piece, the *Ballade des dames du temps jadis,* with its refrain, "Mais où sont les neiges d'antan?", of the ballade of *La Grosse Margot,* with its burden of hopeless entanglement in shameless vice; and of the equally famous *Regrets de la Belle Heaulmière,* in which a woman, once young and beautiful, now old and withered, laments her lost charms. So it is almost throughout his poems, including the grim *Ballade des pendus,* and hardly excluding the very beautiful *Ballade que Villon feist a la requeste de sa mère, pour prier Nostre-Dame,* with its sincere and humble piety. In Villon's verse mediaeval Paris lives. Villon himself was beloved by the Paris of his day. His bright keen intellect, the exquisite polish of his verses and his realism, make him one of the great forces in French poetry. His influence on the moderns has been very great.

His certainly genuine poems consist of the two *Testaments* with their codicil (the latter containing the *Ballade des pendus,* or more properly *Épitaphe en forme de ballade*, and some other pieces of a similarly grim humour), a few miscellaneous poems, chiefly ballades, and an extraordinary collection (called *Le Jargon ou jobelin*) of poems in *argot,* the greater part of which is now totally unintelligible, if, which may perhaps be doubted, it ever was otherwise. Several poems usually printed with Villon's works are certainly, or almost certainly, not his. The chief are *Les Repues Franches,* a curious series of verse stories of cheating tavern-keepers, etc., having some resemblance to those told of George Peele, but of a broader and coarser humour. These, though in many cases "common form" of the broader tale-kind, are not much later than his time, and evidence to reputation if not to fact.

The first dated edition of Villon is of 1489. Before 1542 there were very numerous editions, the most famous being that (1533) of Clément Marot, one of whose most honourable distinctions is the care he took of his poetical predecessors. The Pléiade movement and the classicizing of the *grand siècle* put Villon rather out of favour, and he was not again reprinted till early in the 18th century, when he attracted the attention of students of old French like Le Duchat, Bernard de la Monnoye and Prosper Marchand.

The first critical edition in the modern sense—that is to say, an edition founded on mss. (of which there are in Villon's case several, chiefly at Paris and Stockholm)—was that of the Abbé J. H. R. Prompsault in 1832. The next was that of the "Bibliophile Jacob" (P. Lacroix) in the *Bibliothèque Elzévirienne* (Paris, 1854). The standard editions are *Oeuvres complètes de François Villon,* by M. Auguste Longnon (1892), a revision of this text by Lucien Foulet, *François Villon: Oeuvres* (1923); and L. Thuasne, *François Villon; Oeuvres: édition critique* (1923), based on the Stockholm ms. of 1470, the ms. Fr. 20041 of the Bibliothèque Nationale, and Levet's text of 1489. M. Marcel Schwob discovered new documents relating to the poet, but died before he could complete his work, which was posthumously published in 1905. The researches of Schwob were completed by P. Champion in his *François Villon, sa vie et son temps* (1913). *See* also A. Longnon, *Étude biographique sur François Villon* (1877); Gaston Paris, *François Villon* (1901); D. B. Wyndham Lewis, *François Villon, A Documented Survey* (1928), with preface by H. Belloc, which contains renderings of the individual poems by Rossetti, Swinburne and Henley, and a full survey of the documents.

VILNA or **WILNO,** a province of Poland, having the province of Nowogródek on the south, Russia on the east, Latvia on the north and Lithuania on the west. Area 10,965 sq.m.; pop. (1921) 983,000, of whom 57·4% are Poles, 25·4% White Russians, 5·6% Lithuanians, 8·2% Jews and 3·4% other nationalities. The national struggle has always been fierce in this area, whether between Lithuanians and White Russians, or the persecution of Poles by Russians, or the present feud between Poles and Lithuanians. The district is a Polish island, in White Russian territory, which for centuries formed the centre of the great Lithuanian Ruthenian principality. The World War and its sequel, the Polish Lithuanian feud, has retarded the development of the province. It forms an extension of the Baltic uplands towards the Valdai plateau. The north part is drained by the Disna and just touches the Dvina; the south part is drained by the Wilija. Numerous lakes and marshes, partly covered with forests, and scarcely passable, except when frozen, occupy a great part of the province. Lakes Narocz and Dryswiaty are the largest. The climate is slightly tempered by the proximity of the Baltic sea, but in winter the thermometer descends as low as −30° F. The flora and fauna are intermediate between those of Poland and central Russia. Agriculture and forestry are the main occupations of the inhabitants. The province is backward, and grows mainly rye and oats. It has a considerable export of timber.

There are few towns, the chief of them being Vilna (pop. 128,900), Oszmiana, Swienciany, Molodeczno, Wilejka, Disna and Braslaw. Near Krewo are the ruins of an old castle; at Troki, to which Gedymin moved his capital from Krewo, are the ruins of his castle, standing picturesquely over the lake.

VILNA or **WILNO,** a town of Poland, capital of the province of the same name, 436 m. S.S.W. of Leningrad, at the intersection of the railways from Leningrad to Warsaw and from Libau to the mouth of the Don. Pop. (1921) 128,900. With its suburbs Antokol, Lukishki, Pogulyanka and Sarechye, it stands on and around a knot of hills (2,450 ft.) at the confluence of the Vileika with the Viliya. Its streets are in part narrow and not very clean; but Vilna is an old town, rich in historical associations. Its imperial palace, and the cathedral of St. Stanislaw (1387, restored 1801), containing the silver sarcophagus of St. Casimir and the tomb of Prince Vitoft, are fine buildings. There is a second cathedral, that of St. Nicholas, built in 1596–1604; also several churches dating from the 14th to the 16th centuries. The Ostra Brama chapel contains an image of the Virgin greatly venerated by Orthodox Greeks and Roman Catholics alike. The museum of antiquities has valuable historical collections. The ancient castle of the Jagellones is now a mass of ruins. The old university, founded in 1578, restored (1803) by Alexander I., but closed in 1832 for political reasons was reopened in 1920. Vilna is an archiepiscopal see of the Orthodox Greek Church and an episcopal see of the Roman Catholic Church. The city possesses a botanical garden and a public library. It is an important centre for trade in timber and grain, which are exported; and has theological seminaries, both Orthodox Greek and Roman Catholic. (X.)

History.—Vilna was founded in the 10th century, but became important as the capital of Lithuania (*q.v.*) under Gedymin in 1323. In the early part of the 15th century, Lithuania and Poland coalesced, but owing to their cultural superiority the Poles gradually absorbed Lithuania although in point of territory it was three times the size of Poland. Vilna became a centre of Polish erudition and had a printing-press as early as 1519, but politically ceded pride of place to Warsaw. In the long struggle between Russia, Poland and Sweden which filled the 17th century, the city was nearly ruined. Russia finally retained it in 1795, after the partition of Poland. In 1803 a university was established there, but suppressed for political reasons in 1832. The Polish inhabitants took part in the abortive risings of 1831 and 1863. The town remained the capital of what was now the province of Vilna and became a first class fortress. As such, it fell into German hands after an ephemeral resistance in the autumn of 1915. The question of the political disposal of Vilna therefore did not arise until Poland and Lithuania re-emerged as separate States after the World War of 1914–18. No definite frontier existed between them, but on Dec. 8, 1919, the Supreme Council of the Allies in Paris laid down a provisional eastern frontier for Poland, the so-called "Curzon Line" which assigned to Poland most territories where the Polish element was in a majority, but excluded mixed and doubtful districts, the principal among these being Vilna city and province which the Bolsheviks, with whom the Lithuanians were then at war, had succeeded in capturing for themselves. The provisional Lithuanian Government fled to Kaunas (Kovno). Three months later, the Lithuanians by arrangement with the Poles were on the point of recapturing Vilna when it fell to Polish troops. Obviously, in time of war, this important strategic position at the confluence of two rivers and at the intersection of three railway lines had to be secured quickly. Lithuania made peace with Russia (July 1920), her claim to Vilna being recognised by the Soviet—now that the Poles held it.

Soon after, the Poles, fighting Russia single-handed, lost not only Vilna, but nearly all their country. Nevertheless the face of

the war changed, and the Poles drove back the Bolsheviks who, no longer able to hold Vilna themselves, handed it to Lithuanian troops (end of Aug. 1920), and from that time forth remained consistent in their recognition of the Lithuanian claim. On Oct. 9, Polish troops under the "rebel" general Zeligovski recaptured the town thereby breaking the agreement signed at Suvalki in the presence of the military control commission of the League of Nations two days earlier, whereby the Poles recognised the Lithuanian occupation of Vilna and Vilna region. Since then the Lithuanians have never ceased to protest against the Polish occupation of their historic capital, of two-fifths of their historic territory and the alienation of nearly half their historic population. They had the sympathy of the League of Nations.

But on Jan. 15, 1923, the Lithuanians, imitating the conduct of Zeligovski at Vilna, seized Memel (*q.v.*) by a *coup de main*. On March 15, 1923, the Conference of Ambassadors, in consideration of the peace treaty of Riga between Soviet Russia and Poland, assigned Vilna definitely to Poland. Lithuania refused to accept the ruling, even though the convention signed in Paris (May 8, 1924) gave her Memel and area—the economically valuable "Lithuania Minor"—and maintained a state of "latent war" with Poland ever since, neither regular diplomatic relations nor even direct postal communications being resumed by the end of the year 1928. This manner of conducting policy, apart from the danger to Europe arising from frontier incidents has gravely hurt Vilna. As a result, sympathies which were Lithuanian have been lost.

Among the many attempts by the League of Nations to secure an equitable settlement, two struck at the root of the question. The first, in 1921, was the taking of a plebiscite under the protection of an international force. It failed because the respective governments would not risk being involved in so perilous an experiment, once Soviet Russia threatened to make it a *casus belli* if an inter-European force was assembled near its frontier. The second, also in 1921, was the Hyman's proposal whereunder Vilna was to come under Lithuanian sovereignty as an autonomous canton with special guarantees. It presupposed a permanent military and economic alliance between the two states—of which Lithuania is afraid lest she be a second time absorbed by the culturally superior Poles.

The underlying idea of both these and all other similar schemes is the settlement on the basis of the sovereignty of the national majority—whichever it might prove to be—with adequate guarantees for the racial minorities. However, whether we consider the Russian census of 1897 (which the movement of population during the war has strongly vitiated), or any subsequent reasonably fair statistics, one thing is clear: within the limits of Vilna City the Poles are in a majority. On the other hand, within the area of the former Russian province, live, according to Polish admission about 80,000 Lithuanians, according to the Kovno authorities not less than half a million. But the latter includes so-called "denationalized" Lithuanians by which are meant persons of Lithuanian origin who have long ago abandoned their language for the reason that, until its post-war revival, it was little more than a primitive peasant-tongue. The question is further complicated by the existence of pure Polish "islands" within the admittedly Lithuanian areas, not to mention the very large Russian settlements.

See POLAND; LITHUANIA; also League of Nations *Official Journal* (spec. Suppl. 4) and the Lithuanian Press Bureau's *The Lithuanian-Polish Dispute* (3 vol. 1922). (W. L. B.)

VIMEIRO, BATTLE OF, 1808. Advancing upon Lisbon (*see* PENINSULAR WAR), Wellesley halted to cover the landing of reinforcements at the mouth of the Alcabrichella. Two miles from the sea this river cuts its way through a high ridge, which it divides into a western and an eastern section; at the southern entrance of the gorge thus formed lies the village of Vimeiro. Wellesley's force, 20,000 strong, was encamped upon the western ridge, with two brigades upon Vimeiro hill, a knoll just south of the village. On the morning of Aug. 21, 1808, Wellesley learned that Junot, with 13,000 men, was advancing to attack him. Junot, ignoring the western ridge, directed the brigades of Thomières and Charlot to attack Vimeiro hill, while Brennier mounted the eastern ridge and swept along it from the east. Wellesley at once sent five brigades on to the eastern ridge, two to overlook Vimeiro hill and three to stop Brennier's advance along its crest. The attack on Vimeiro hill followed a course that was to be the pattern for many such engagements throughout the war. The French advanced in solid columns on a narrow frontage, having thus little fire power; the British received them in line, wrapping themselves round the head and flanks of the columns, withered them with volleys of musketry, charged with the bayonet and swept them down the hill with heavy loss. A second attack by four battalions of grenadiers met with a similar fate, though two battalions did fight their way into Vimeiro village and were only dislodged after heavy hand-to-hand fighting. Meanwhile Brennier had lost himself among ravines north of the eastern ridge, but Solignac, who had been sent to reinforce him, struck correctly westwards along the ridge and blundered into three British brigades in line. Within a few minutes Solignac's brigade had practically ceased to exist, but as the bulk of the British chased joyfully along the ridge in pursuit of the survivors Brennier's brigade came up from the valley behind them and roughly handled two battalions that had been left to guard Solignac's abandoned guns. Fortunately their comrades returned in time to scatter Brennier's men. The moment was ripe for a general advance and pursuit of Junot's beaten army, but Sir Harry Burrard at this point arrived to take over command from Wellesley and timidly ordered hostilities to cease. Junot had lost half his guns and a quarter of his men, the British loss being only 750.

VINCENNES, a suburb 7 kilometres east of Notre Dame de Paris, in the department of Seine, on a wooded plateau. Pop. (1926), 41,836. Its celebrated castle, situated to the south of the town and on the northern border of the Bois de Vincennes, was formerly a royal residence, begun by Louis VII. in 1164, and more than once rebuilt. It was frequently visited by Louis IX. The chapel, an imitation of the Sainte Chapelle at Paris, was begun by Charles V. in 1379, continued by Charles VI. and Francis I., consecrated in 1552 and restored in modern times. In the sacristy is the monument erected in 1816 to the memory of the duke of Enghien, who was shot in the castle moat in 1804. Louis XI. made the castle a state prison in which Henry of Navarre, the great Condé, Mirabeau and other distinguished persons were afterwards confined. Louis XVIII. added an armoury, and under Louis Philippe numerous casemates and a new fort to the east of the donjon were constructed. Vincennes has a school of military administration and carries on horticulture and the manufacture of ironware, rubber goods, chemicals, etc.

VINCENNES, a city of S.W. Indiana, U.S.A., on the Wabash river; the county seat of Knox county, the oldest settlement of the State. It is on federal highways 41 and 50; has a municipal airport; and is served by the Baltimore and Ohio, the Big Four, the Chicago and Eastern Illinois, and the Pennsylvania railways. Pop. (1920) 17,160 (94% native white); estimated locally at 21,000 in 1928. Vincennes is in a rich agricultural region, surrounded by vast coalfields. Its manufactures include structural steel, pearl buttons (from mussel shells taken from the Wabash), glass, shoes, ploughs, fertilizer, ice-cream moulds, flour, and ketchup. A French trading post was established on the site of Vincennes probably as early as 1702, and about 1731 a fortification was erected by François Margane, Sieur de Vincennes, around which a permanent settlement soon grew up. It remained under French sovereignty until 1777, was occupied by the British and named Fort Sackville. On February 25, 1779, it was captured by George Rogers Clark, returning after his expedition to Kaskaskia. Vincennes was the capital of Indiana Territory from 1800–13. It was incorporated as a borough in 1839 and became a city in 1856. Buildings of historic interest still standing (1929) include: the house in which the first Territorial legislature met on July 9, 1805; the Governor's mansion, built by William Henry Harrison, the first governor of the territory; and Vincennes University, opened in 1806, now a junior college. The county court-house was built in 1873–4 as a memorial to the pioneers and soldiers of Knox county.

VINCENT (or VINCENTIUS), **ST.,** deacon and martyr, whose festival is celebrated on Jan. 22. In several of his discourses St. Augustine pronounces the eulogy of this martyr, and refers to *Acts* which were read in the church. It is doubtful whether the *Acts* that have come down to us (*Acta Sanctorum*, January, ii. 394–397) are those referred to by St. Augustine, since it is not certain that they are a contemporary document. According to this account, Vincent was born of noble parents in Spain, and was educated by Valerius, bishop of Saragossa, who ordained him to the diaconate. Under the persecution of Diocletian, Vincent was arrested and taken to Valencia. He was subjected to excruciating tortures and thrown into prison, where angels visited him, lighting his dungeon with celestial light and relieving his sufferings. His warders, having seen these wonders through the chinks of the wall, forthwith became Christians. He died in an interval when new torments were being prepared. His body, exposed to the wild beasts in vain, was thrown into the sea, but was recovered and buried outside Valencia.

See T. Ruinart, *Acta martyrum sincera* (Amsterdam, 1713), pp. 364–366; Le Nain de Tillemont, *Mémoires pour servir à l'histoire ecclésiastique* (Paris, 1701, *seq.*), v. 215–225, 673–675.

VINCENT, GEORGE EDGAR (1864–), American educationalist, was born at Rockford, Ill., on March 21, 1864. After graduating at Yale in 1885, he engaged in editorial work and in 1886 was made literary editor of the Chautauqua press. He was president of the Chautauqua institution from 1907 to 1915 and thereafter honorary president. In 1892 he was appointed fellow at the University of Chicago. He taught at Chicago as instructor, assistant professor, associate professor, and from 1904 to 1911 as professor of sociology. He was dean of the junior colleges from 1900 to 1907, and then for four years was dean of the faculties of arts, literature and sciences. From 1911 to 1917 he was president of the University of Minnesota. In 1917 he was chosen president of the Rockefeller Foundation in New York city; he had been a member of the General Education Board since 1914. Vincent has written *The Social Mind and Education* (1897), and with Albion W. Small *An Introduction to the Study of Society* (1894).

VINCENT DE PAUL, ST. (1576–1660), French divine, founder of the "Congregation of Priests of the Mission," usually known as Lazarites (*q.v.*), was born on April 24, 1576 at Pouy, near Dax, in Gascogne, and was educated by the Franciscans at Dax and at Toulouse. He was ordained priest in 1600. Voyaging from Toulouse to Narbonne, he was captured by Barbary pirates, who took him to Tunis and sold him as a slave. He converted his third master, a renegade Italian, and escaped with him to Aigues-Mortes near Marseilles in June 1607. After short stays at Avignon and Rome, Vincent found his way to Paris, where he became acquainted with Pierre de Bérulle (*q.v.*), who found him a curacy at Clichy near Paris (1611). He then became tutor to the count of Joigny at Folleville, in the diocese of Amiens, where his success with the peasants led to the "missions" with which his name is associated. In 1617 he became curate of Châtillon-lès-Dombes (or sur-Chalaronne), and the countess of Joigny supplied him with money to found his first *confrérie de charité*, an association of women who ministered to the poor and the sick.

Among the works of benevolence with which his name is associated are the establishment of a hospital for galley slaves at Marseilles, the institution of two establishments for foundlings at Paris, and the organization of the *Filles de la Charité*, to supplement the work of the *confréries*, whose members were mainly married women with domestic duties. He died at Paris on Sept. 27, 1660, and was buried in the church of St. Lazare. He was beatified by Benedict XIII. in 1729, and canonized by Clement XII. in 1737.

The Society of St. Vincent de Paul was founded by Frédéric Ozanam and others in 1833.

Lives by Maynard (4 vols., Paris, 1860), Bougaud (2 vols., Paris, 1891), E. de Broglie (5th edition, Paris, 1899); *Letters* (2 vols., Paris, 1882); A. Loth (Paris, 1880); H. Simard (Lyons, 1894); E. K. Sanders, *V. de Paul, priest and philanthropist* (1913).

VINCENT OF BEAUVAIS, or VINCENTIUS BELLOVACENSIS (*c.* 1190–*c.* 1264), the encyclopaedist of the middle ages, was probably a native of Beauvais. The exact dates of his birth and death are unknown. A tolerably old tradition, preserved by Louis a Valleoleti (*c.* 1413), gives the latter as 1264; but Tholomaeus de Luca, Vincent's younger contemporary (d. 1321), seems to reckon him as living during the pontificate of Gregory X. (1271–76). If we assume 1264 as the year of his death, the immense volume of his works forbids us to think he could have been born much later than 1190. Very little is known of his career. It is certain, however, that he at one time held the post of "reader" at the monastery of Royaumont (*Mons Regalis*), not far from Paris, on the Oise.

The *Speculum Majus*, the great compendium of all the knowledge of the middle ages, as it left the pen of Vincent, seems to have consisted of three parts only, viz., the *Speculum Naturale*, *Doctrinale* and *Historiale*. Such, at least, is Échard's conclusion, derived from an examination of the earliest extant mss. All the printed editions, however, consist of four parts, the additional one being entitled *Speculum Morale*. This has been clearly shown to be the production of a later hand, and is ascribed by Échard to the period between 1310 and 1325.

The *Speculum Naturale* is divided into thirty-two books and 3,718 chapters. It is a vast summary of all the natural history known to western Europe towards the middle of the 13th century. It is, as it were, the great temple of mediaeval science, whose floor and walls are inlaid with an enormous mosaic of skilfully arranged passages from Latin, Greek, Arabic and Hebrew authors.

The *Speculum Doctrinale*, in seventeen books and 2,374 chapters, is a summary of all the scholastic knowledge of the age. It is intended to be a practical manual for the student and the official alike; and, to fulfil this object, it treats of the mechanic arts of life as well as the subtleties of the scholar, the duties of the prince and the tactics of the general. It also treats of mathematics, under which head are included music, geometry, astronomy, astrology, weights and measures, and metaphysics. It is noteworthy that in this book Vincent shows a knowledge of the Arabic numerals, though he does not call them by this name. The last book (xvii.) treats of theology or mythology, and winds up with an account of the Holy Scriptures and of the Fathers, down to Bernard of Clairvaux and the brethren of St. Victor.

As the fifteenth book of the *Speculum Doctrinale* is a summary of the *Speculum Naturale*, so the *Speculum Historiale* may be regarded as the expansion of the last book of the same work. It consists of thirty-one books divided into 3,793 chapters. It brings history down from the creation to the crusade of St. Louis. Four of the mediaeval historians from whom he quotes most frequently are Sigebert of Gembloux, Hugh of Fleury, Helinand of Froidmont, and William of Malmesbury.

Vincent has hardly any claim to be reckoned as an original writer. But it is difficult to speak too highly of his immense industry in collecting, classifying and arranging these three huge volumes of 80 books and 9,885 chapters. The undertaking to combine all human knowledge into a single whole was in itself a colossal one and could only have been born in a mind of no mean order. Indeed more than six centuries passed before the idea was again resuscitated; and even then it required a group of brilliant Frenchmen to do what the old Dominican did unaided.

A list of Vincent's works, both ms. and printed, will be found in the *Histoire littéraire de France*, vol. xviii., and in Jacques Échard's *Scriptores ordinis praedicatorum* (1719–21). The *Tractatus consolatorius pro morte amici* and the *Liber de eruditione filiorum regalium* (dedicated to Queen Margaret) were printed at Basle in December 1480.

Boutaric, *Examen des sources du Speculum historiale de Vincent de Beauvais* (Paris, 1863); and in tome xvii. of the *Revue des questions historiques* (Paris, 1875); W. Wattenbach, *Deutschlands Geschichtsquellen*, vol. ii. (1894); B. Hauréau, *Notices . . . de MSS. latins de la Bibliothèque Nationale*, tome v. (1892); and E. Mâle, *L'art religieux du XIIIe siècle en France*.

VINCENT OF LERINS, ST., or VINCENTIS LERINENSIS (d. *c.* A.D. 450), theologian, was a native of Gaul, possibly brother of St. Loup, bishop of Troyes. He became a monk and priest at Lerinum (Lerins), an island off Cannes, and died in or about 450. The monastery of Lerins produced many eminent churchmen,

among them Hilary of Arles. In 434, three years after the council of Ephesus, he wrote the *Commonitorium adversus profanas omnium haereticorum novitates*, in which he ultimately aims at Augustine's doctrine of grace and predestination. In it he discusses the "notes" which distinguish Catholic truth from heresy, and (cap. 2) lays down and applies the famous threefold test of orthodoxy—*quod ubique, quod semper, quod ab omnibus creditum est.*

The *Commonitorium* has been edited by Baluze (Paris, 1663, 1669 and 1684), by Klüpfel (Vienna, 1809), and by R. S. Moxon (1915). It also occurs in vol. i. of Migne's *Patrol. Ser. Lat.* (1846). A full summary is given in A. Harnack's *History of Dogma*, iii. 230 ff. *See* also F. H. Stanton, *Place of Authority in Religion*, pp. 167 ff.; A. Cooper-Marsdin, *The School of Lerins* (Rochester, 1905).

VINDELICIA, in ancient geography, a country bounded on the south by Rhaetia, on the north by the Danube and the Vallum Hadriani, on the east by the Oenus (Inn), on the west by the territory of the Helvetii. It thus corresponded to the north-eastern portion of Switzerland, the south-east of Baden, and the south of Württemberg and Bavaria. Together with the neighbouring tribes it was subjugated by Tiberius in 15 B.C., and towards the end of the 1st century A.D. was made part of Rhaetia.

VINDHYA, a range of mountains in Central India. They form a well-marked, though not continuous, chain with the river Narbada on the south and separate the Ganges basin from the Deccan. Starting on the west in Gujarat, they cross the southern edge of the Malwa plateau and, continued by the Bhanrer and Kaimur ranges, abut on the Ganges valley near Benares. They have an elevation of 1,500 to 4,500 ft., nowhere exceeding 5,000 ft.

They are built of the "Vindhyan formation" (part of the Pre-Cambrian rocks of India). Traditionally they formed the boundary between the Madyadesha of the Sanskrit invaders and the non-Aryan Deccan.

VINE. The grape-vine, botanically *Vitis* (family Vitaceae), is a genus of about 40 species, widespread in the north temperate zone, but richest in species in North America. The best known and longest cultivated species is the old-world grape-vine, *Vitis vinifera;* a variety of this, *silvestris,* occurs wild in the Mediterranean region, spreading eastwards towards the Caucasus and northwards into southern Germany, and may be regarded as the parent of the cultivated vine.

History and Distribution.—It is of interest to note that grape-stones have been found with mummies in Egyptian tombs not less than 3,000 years old. The seeds have the characteristics of those of *V. vinifera,* but show some very slight variations from the type of seed now prevalent. Among the Greeks in the time of Homer wine was in general use. The cultivation of the vine must also have been introduced into Italy at a very early period. In Virgil's time the varieties in cultivation seem to have been exceedingly numerous; and the varied methods of training and culture now in use in Italy are in many cases identical with those described by Columella and other Roman writers. Grape-stones have been found among the remains of Swiss and Italian lake dwellings of the Bronze period, and others in tufaceous volcanic deposits near Montpellier, not long before the historic era.

The Old World species is also extensively cultivated in California, but the grape industry of the eastern United States has been developed from native species, chiefly *V. Labrusca* (northern fox grape), *V. aestivalis* (summer grape) and *V. rotundifolia* (southern fox grape, giving the muscadine grapes with the well known variety scuppernong), and their hybrids with *V. vinifera.* Some of the American varieties have been introduced into France and other countries infested with *Phylloxera,* to serve as stocks on which to graft the better kinds of European vines, because their roots do not suffer so much injury from the attacks of this insect as do European species.

The vine requires a high summer temperature and a prolonged period in which to ripen its fruit. Where these are forthcoming, it can be profitably cultivated, even though the winter temperature be very low. Tchihatchef mentions that at Erivan in Russian Armenia the mean winter temperature is 7°·1 C and falls in January to −30° C, and at Bukhara the mean temperature of January is 4° C and the minimum −22° C, and yet at both places the vine is grown with success. In the Alps it is profitably cultivated up to an altitude of 1,000 ft., and in the north of Piedmont as high as 3,000 ft. At the present time the limit of profitable cultivation in Europe passes from Brittany, lat. 47° 30′, to beyond the Rhine by Liége and through Thuringia to Silesia in lat. 51° 55′. In former centuries vines were cultivated farther north.

Apart from their economic value (*see* CURRANT; RAISIN; WINE), vines are often cultivated for purely ornamental purposes, owing to the elegance of their foliage, the rich colouration they assume, the shade they afford, and their hardihood.

FROM KOEHLER, "MEDIZINAL PFLANZEN"

VINE (VITIS VINIFERA), SHOWING BRANCHES WITH FLOWERS AND FRUIT

Vegetative Characters.—Vines have woody climbing stems, with alternate, entire or palmately lobed leaves, provided at the base with small stipules. Opposite some of these leaves springs a tendril, by aid of which the plant climbs. The flowers are small, green and fragrant, and are arranged in dense clusters. Each has a small calyx in the form of a shallow rim, sometimes five-lobed or toothed; five petals, which cohere by their tips and form a cap or hood, which is pushed off when the stamens are ripe; and five free stamens, placed opposite the petals and springing from a fleshy ring or disk surrounding the ovary; each bears a two-celled anther. The ovary bears a sessile stigma and is more or less completely two-celled, with two erect ovules in each cell. This ripens into the berry and seeds.

The seeds or grape-stones are somewhat club-shaped, with a narrow neck-like portion beneath, which expands into a rounded and thickened portion above. On the inner or central side of the seed is a ridge bounded on either side by a shallow groove. This ridge indicates the point of union of the "raphe" or seed-stalk with the seed; it serves to distinguish the varieties of *V. vinifera* from those of other species. In endeavouring to trace the filiation and affinities of the vine, the characters afforded by the seed are specially valuable, because they have not been wittingly interfered with by human agency.

Cultivation Under Glass.—When the plant is grown under glass, the vine border should occupy the interior of the house and also extend outwards in the front, but it is best made by instalments of 5 or 6 ft. as fast as the previous portions become well filled with roots, which may readily be done by packing up a turf wall at the extremity of the portion to be newly made; an exterior width of 15 ft. will be sufficient. Inside borders require frequent and thorough waterings. In well-drained localities the border may be partially below the ground level, but in damp situations it should be made on the surface; in either case the firm solid bottom should slope outwards towards an efficient drain. A good bottom

may be formed by chalk rammed down close. On this should be laid at least a foot thick of coarse, hard, rubbly material, a layer of rough turf, grass side downwards, being spread over it to prevent the compost from working down. The soil itself, which should be 2½ or 3 ft. deep, never less than 2 ft., should consist of five parts rich turfy loam, one part old lime rubbish or broken bricks, including a little wood ashes or burnt earth (ballast), one part broken charcoal, and about one part of half-inch bones, the whole being thoroughly mixed, and kept dryish till used.

Young vines raised from eyes, *i.e.*, buds having about ¼ in. wood above and 1 in. below, are generally preferred for planting. The eyes being selected from well-ripened shoots of the previous year are planted about the end of January, singly, in small pots of light loamy compost, and after standing in a warm place for a few days should be plunged in a propagating bed, having a bottom heat of 75°, which should be increased to 85° when they have produced several leaves, the atmosphere being kept at about the same temperature or higher by sun heat during the day, and at about 75° at night. As soon as roots are freely formed the plants must be shifted into 6-inch pots, and later on into 12-inch ones. The shoots are trained up near the glass, and, with plenty of heat (top and bottom) and of water, with air and light, and manure water occasionally, will form firm, strong, well-ripened canes in the course of the season. To prepare the vine for planting, it should be cut back to within 2 ft. of the pot early in the season, and only three or four of the eyes at the base should be allowed to grow on. The best time for planting is in spring, when the young shoots have just started. The vines should be planted inside the house, from 1 to 2 ft. from the front wall, and from 6 ft. to 8 ft. apart, the roots being placed an inch deeper in the soil than before.

When the shoots are fairly developed, the two strongest are to be selected and trained in. When forcing is commenced, the vinery is shut up for two or three weeks without fire heat, the mean temperature ranging about 50°. Fire heat must be at first applied very gently, and may range about 55° at night, and from 65° to 70° by day, but a few degrees more may be given them as the buds break and the new shoots appear. When they are in flower, and onwards during the swelling of the berries, 85° may be taken as a maximum, running up to 90° with sun heat and the temperature may be lowered somewhat when the fruit is ripe. As much ventilation as the state of the weather will permit should be given. A due amount of moisture may be kept up by the use of evaporating troughs and by syringing the walls and pathways two or three times a day, but the leaves should not be syringed.

Pruning.—There are three principal systems of pruning vines, termed the *long-rod*, the *short-rod* and the *spur* systems, and good crops have been obtained by each of them. The spur system has, however, become the most general. In this case the vines are usually planted so that one can be trained up under each rafter, or up the middle of the sash, the latter method being preferable. The shoots are cut back to buds close to the stem, which should be encouraged to form alternately at equal distances right and left, by removing those buds from the original shoot which are not conveniently placed. The young shoots from these buds are to be gently brought to a horizontal position, by bending them a little at a time, and tied in, and usually opposite about the fourth leaf the rudiments of a bunch will be developed. The leaf directly opposite the bunch must in all cases be preserved, and the young shoot is to be topped at one or two joints beyond the incipient fruit, the latter distance being preferable if there is plenty of room for the foliage to expand. If the bunches are too numerous they must be thinned before the flowers expand, and the berries also must be properly thinned out and regulated as soon as they are well set.

Cultivation in Pots.—This is very commonly practised with good results, and pot-vines are very useful to force for the earliest crop. The plants should be raised from eyes, and grown as strong as possible in the way already noted, in rich turfy loam mixed with about one-third of horse dung and a little bone dust. The temperature should be gradually increased from 60° to 80°, or 90° by sun heat, and a bottom heat a few degrees higher must be maintained during their growth. As the roots require more room, the plants should be shifted from 3-inch pots into those of 6, 12 or 15 in. in diameter, in any of which larger sizes they may be fruited in the following season, but, to be successful in this, the young rod produced must be thoroughly matured after it has reached its limit of growth. The periodical thorough cleansing of the vine stems and every part of the houses is of the utmost importance to keep down insect pests. (X.)

Grape Diseases.—All cultivated, as well as wild grapes, are subject to diseases. These diseases are due either to plant parasites or physiological disturbances caused by abnormal or unfavourable environment. The causative factors involve nutrition, soil and climate.

The principal fungus diseases are black rot, caused by *Guignardia bidwellii;* downy mildew, caused by *Plasmopara viticola;* powdery mildew, caused by *Uncinula necator;* anthracnose, caused by *Sphaceloma ampelinum;* ripe rot, caused by *Glomerella cingulata;* dead arm, caused by *Cryptosporella viticola;* bitter rot, caused by *Melanconium fuligineum;* white rot, caused by *Coniothyrium diplodiella;* crown gall, caused by *Bacterium tumefaciens,* and rougeot, caused by *Pseudopeziza tracheiphila.* Most of these diseases are found wherever grapes are cultivated, except in irrigated, arid regions, where powdery mildew is the principal trouble. The so-called physiological or non-parasitic diseases are most frequently found in such regions also. The principal non-parasitic diseases are known as California vine disease, Spanish measles and Little-leaf. Their exact cause has not yet been determined and satisfactory methods of prevention are not known. The principal means of control of the fungus diseases is the application of Bordeaux mixture. Sulphur dust is used for powdery mildew in arid regions. (C. L. S.)

Injurious Insects.—A list of the insects which subsist wholly or in part on the fruit, foliage, roots or other parts of the grape in the various countries of the world where the fruit is grown would comprise probably not less than 1,000 species. Fortunately, these insects are still mostly restricted to the respective countries where they are indigenous, since, with but few exceptions, there has been but little exchange of grape insects between countries by commerce or otherwise. An important exception is the grape *Phylloxera,* a plant louse native to central and eastern North America, occurring on various wild grapes. This insect found its way to Europe as early as 1868, where its injuries to the roots of *vinifera* or European grapes seriously threatened the vine-growing industry. Later it appeared in California, perhaps direct from Europe, where great damage was done to *vinifera* varieties. Injuries are now fairly well avoided in Europe, and also in California, by using for grafting purposes the roots of resistant American vines. In America the outstanding grape pests are the *Phylloxera* (*Phylloxera viticola*) in *vinifera* districts; leafhoppers (*Typhlocyba* spp.); the berry moth (*Polychrosis viteana*); root worm (*Fidia viticida*); rose chafer (*Macrodactylus subspinosus*); caterpillars of various moths (*Desmia funeralis, Alypia octomaculata, Memythrus polistiformis, Pholus achemon*); certain beetles, as *Haltica chalybea, Craponius inaequalis* and *Adoxus obscurus.* (A. L. Q.)

GRAPE CULTURE IN EUROPE

The cultivation of the vine is an important industry in all the countries of southern Europe, where its product is chiefly converted into wine. The production of good table grapes is more difficult and also more limited. As a result they are in demand and profitably raised under glass in the more northerly countries, the indoor product also being usually superior in size and sometimes in quality to outdoor table grapes.

Great Britain.—The vine is hardy in Great Britain so far as regards its vegetation, but it is not hardy enough, except when cultivated under glass, to bring its fruit to satisfactory maturity, so that for all practical purposes the vine must be regarded as a tender fruit. Planted against a wall or a building having a south aspect, or trained over a sunny roof, such varieties as the Black Cluster, Black Prince, Pitmaston White Cluster, Royal Muscadine, Sweetwater, etc., will ripen in the warmest English summers so as to be very pleasant eating; but in cold summers

the fruit is not eatable in the raw state.

France.—France continues to rank second among all countries in the world in the area of her vineyards, although they have decreased from 2·4 million hectares in 1874 to 1·36 million hectares in 1924. Holdings are usually small. Of the 1,565,000 vine-growers reporting in 1924 over 70% reported vineyards of less than one hectare in extent. The harvests of wine (not counting Alsace-Lorraine) for the 6 years, 1919–24, averaged 58,100,000 hectolitres (1,535 million gal.). The production for 1927 was 48,890,000 hectolitres, an amount considerably below normal. In volume the Mediterranean counties produced over half the entire amount. The second wine region in point of output is the Bordeaux area, chiefly in the valleys of the Garonne, Dordogne and Charente rivers. In this region are grown the grapes from which the two most famous French brandies, cognac and armagnac, are distilled. The eastern area, covering about 10 counties, comprises the regions in which the well-known Burgundy, Beaujolais and Mâcon wines are produced. The yield of the Loire region (principally *vins rosés*, white and sparkling wines) has grown less, amounting to but 354,000 hectolitres in 1927. The grapes from which champagne is made are grown almost entirely in the Marne county. The product of Alsace-Lorraine comprises mainly white wines of the Rhine and Moselle types and amounted in 1926 to 224,000 hectolitres. The output of Algeria, of which the bulk is consumed in France, amounted to 12,400,000 hl. in 1925 and 8,400,000 hl. in 1927; that of Tunis was about 900,000 hl. of which about 550,000 hl. were exported to France. The quantity of production bears no relation to the quality, and the latter varies greatly in different localities even in the same year. Damp weather and lack of sun seriously affect the sugar and alcoholic content of the wine. France imports more wine than she exports, importing much from Spain, Algiers, and Greece for blending. Better wines from Spain, Portugal and Italy are imported to be consumed without blending, or for dessert or liqueur wines.

Spain and Portugal.—The acreage devoted to vineyards has increased in both Spain and Portugal in recent years. That of Spain, 1·35 million hectares, closely approaches that of France and gives the country a ranking of third among grape-producing countries. The wine crop was abundant in Spain in 1927 amounting to 28,325,192 hl. as compared with 15,753,538 hl. in 1926. The average production is about midway between. The industry gives employment to between 3,000,000 and 4,000,000 people. Seville, Barcelona, Andalusia and Tarragona are the principal producing districts. Exports of Málaga and Almería grapes are heavy, while over half of the Málaga crop is made into high quality raisins which are widely distributed over the world and furnish the chief competition for the raisins of California. An unofficial estimate placed the production of wine in Portugal at 6,273,200 hl. for 1927, an amount about one-third greater than normal. The area under vintage in 1926 was 345,000 hectares. Exports of port wine amounted in 1927 to $11,142,000 and of other wine to $14,073,000.

Italy and Eastern Europe.—Italy has a larger area given over to vineyards than any other country in the world, the total being in the neighbourhood of two million hectares. The total production of grapes in 1927 was 57,958,000 metric quintals as against a 5-year average of 68,164,000 metric quintals. Wine production was 35,650,000 hectolitres, also less than average. The year saw poor crops in southern Italy, especially in Latium, Apulia and Sicily.

Vineyards also form one of the principal industries of Greece. The country produces enough wine to meet its local needs and exports a quantity which has increased from 60,000 tons in 1925 to 139,000 tons in 1927. Two-thirds of the vineyards are in old Greece. Due to *phylloxera* the cultivation of the vine all but died out in Macedonia where the industry is now being revived by refugee settlers. The government is aiding both by loans and by the distribution of plants and cuttings. The total grape production of Greece was 275,000 metric tons in 1927.

A comparative view of the importance of the vine in other countries of Europe is shown in the following statistics of production for 1927:

Country	Area in vineyards	Wine production
Rumania	695,000 acres	191,200,000 gal.
Hungary	542,000 "	51,566,000 "
Yugoslavia	441,000 "	75,428,000 "
Germany	181,872 "	31,407,618 "
Bulgaria	180,373 "	. . . . .
Switzerland	37,000 "	9,240,000 "

GRAPE CULTURE IN THE UNITED STATES

In the United States the term grape is generally used to denote not only the fruit but also the plant that produces it; the word vine when used alone means any twining or climbing plant and not, as in England, meaning solely the grape-producing plant.

History.—When the early discoverers visited North America wild grape vines were so prominent that the region was repeatedly called vineland. John Adlum's vineyard near Georgetown, D.C., planted in 1820, first produced grapes successfully on the Atlantic coast. Adlum's introduction of the Catawba into general culture and improvement gave to the world valuable new fruits. In 1860 nine-tenths of the 5,600 ac. of vineyard established east of the Rocky Mountains were Catawba grapes and little was then known regarding such varieties as Concord, Delaware, Hartford, Iona, Adirondack and Rogers hybrids. From 1860 to 1870 there was rapid increase in acreage of improved varieties derived from native American grapes. Concord became and still remains the leading variety of American origin commercially grown. The Mission Fathers in California were the first to grow successfully a variety (the Mission) of the Old World grape (*V. vinifera*) in the United States. They brought it to San Diego, Calif., in 1769. The Mission remained the leading variety grown until 1860, when the choicest European kinds were introduced.

Grape Regions.—Viticulture in the United States comprises three regions which are distinguished by the grape species grown in each:

The *Vinifera Region*, in which forms of the Old World vine (*V. vinifera*) are grown for all purposes, is almost entirely in California. Eighty-five per cent of the viticultural output of the United States are vinifera grapes. These are usually planted 8×8, 9×9, 8×10 or 8×12 ft. apart. Cane or spur renewal pruning with vines trained to stakes is practised with all varieties excepting Sultanina and Emperor, which are pruned to a four-arm renewal system and trained on a two-wire upright trellis. In untrellised vineyards cross ploughing methods are employed.

The *American Euvitis Region*, in which improved varieties and hybrids of the more northern hardier American species with vinifera are grown, covers in its broadest sense the entire United States. It is most extensive, however, in the States west of the Hudson and north of the Ohio rivers, in States bordering on the Great Lakes and in the more central States of the Mississippi valley. These grapes are mostly pruned to the four-arm renewal system and trained to a two-wire upright trellis; of late years, however, the modified Munson system is rapidly gaining favour.

The *Muscadine Region* is the area in which improved varieties of *V. rotundifolia* are grown for commercial purposes. These are native varieties which thrive under suitable conditions throughout the Coastal Plain from the James river to Florida, reaching well up into the Blue Ridge mountains, and along the Gulf coast to Texas and northward along the Mississippi river to southeastern Missouri and the Tennessee river. These vines are usually grown on an overhead arbour trellis and planted 20×20 ft. apart.

In 1927 there were about 900,000 ac. of vineyard in the United States, of which 675,000 ac. were in California; the next largest acreages were in New York, Michigan, Ohio, Pennsylvania, and Missouri, in the order named.

The Grape Industry.—The 1889 grape crop was valued at

$2,846,748. Of this 42% was converted into wine and brandy, 47% used as table grapes and 11% cured as raisins and dried grapes. The use of grapes in the fresh state and cured into raisins had then become important. In 1899 there was nearly 100% increase over 1889 in vineyard acreage and grape crop. In 1909, 2,571,065,205 lb. of grapes were produced, which furnished 52,912,396 gal. of wine and unfermented juice, 6,393,150 gal. brandy, 24,470 cases canned grapes, 104,400,000 lb. raisins and dried grapes and 18,640 cars of table grapes. During the decade ending with 1909 the commercial manufacture of unfermented grape juice had become an industry.

In 1919 the grape output of America from 320,000 ac. was 2,513,680,861 lb., used in 32,551,937 gal. of wines and juices, 1,802,421 gal. of brandy, 104,446 cases canned grapes, 28,495 car loads fresh grapes shipped and 395,000,000 lb. of raisins. The adoption of the Prohibition Amendment caused many radical changes in the utilization of grapes. In 1927 the total grape crop of the United States from 710,000 ac. amounted to 2,604,712 tons, valued at $65,000,000. Of this California produced 2,404,000 tons or 92⅓%; Michigan, 51,700 tons; New York, 51,526; Ohio, 20,000; Pennsylvania, 14,850; Missouri, 7,000; Iowa, 5,329; North Carolina, 5,135; Kansas, 3,735; Oregon, 3,500; Illinois, 3,440; Washington, 3,200; and Arkansas, 3,000 tons.

(G. C. H.)

Robbins, *Botany of Crop Plants* (Philadelphia, 1924); L. H. Bailey, *Manual of Cultivated Plants* (1924) and *Standard Cyclopaedia of Horticulture* (1914–27).

VINEGAR. There can be no doubt that vinegar was first obtained by the natural souring of fermented wine, whence it received its name; the alcohol natural to wine or beer, under appropriate conditions, readily becomes oxidized by the atmosphere to form acetic acid—a change represented by the chemist by the expression

$$\underset{\text{Alcohol}}{CH_3CH_2OH} + \underset{\text{Oxygen}}{O_2} \rightarrow \underset{\text{Acetic Acid}}{CH_3COOH} + \underset{\text{Water}}{H_2O}$$

The interesting mechanism of this change has only been understood of quite recent years. Just as the alcohol in wine or beer is produced by living agency (*see* FERMENTATION), so the subsequent acetous fermentation is due to a micro-organism, the vinegar bacillus or *Bacterium aceti*. The curious and complicated recipes of mediaeval writers for the preparation of vinegar owed their success to the fact that they unwittingly involved infection with and the promotion of these organisms. Distinguished scientists, such as Liebig and Döbereiner, had chemical theories for acetification but the truth was not discovered until Pasteur in 1864 confirmed experimentally the view put forward in 1837 that the living cells which formed a scum on the beer were really responsible for the changes observed. Hansen in 1878 described for the first time the three species of vinegar bacilli.

Vinegar brewing as a separate industry dates from about the 17th century when it was established in France. Prior to that it was just a by-product of the wine producer and the brewer. The connection between the brewing and vinegar industry in England is shown by the Revenue Acts which, in the reign of Charles II. charged different duties on beer and on vinegar-beer. There are two well-known methods of manufacture, the slow process and the quick one; the latter has now almost superseded the former except for the preparation of pure wine vinegar as distinct from ordinary or malt vinegar. In the slow process the alcoholic wash, whether prepared from wine or not, must contain 10% of alcohol; it is filled into casks holding 50 or 100 gallons, which are half-full of beech shavings and have previously been impregnated with vinegar. In these casks it is exposed to the atmosphere, by the simple expedient of leaving the bung-holes open until all the alcohol has been converted into acetic acid. The exposure was formerly in a field or yard but is now often in a special building, so that the casks may be kept slightly warm; the acetified gyle is filtered and stored. This process is chiefly used in the Orleans district of France and has the merit of producing a vinegar of peculiarly fine aroma; it is, however, slow and wasteful and liable to various disturbing factors, such as the development of vinegar eels.

The Modern Process.—The more modern and efficient process is that of malt vinegar manufacture, the first stages of which are closely similar to those used in the preparation of beer. A quantity of malt—about one quarter per 150 gallons—is crushed and extracted with hot water in the mash tun or tank at a temperature of about 68° C (155° F), the whole mash being well raked over so that all the soluble sugars may be extracted. After running off the infusion the grain is "sparged" by a stream of hot water from perforated revolving pipes arranged over the top of the mash tun. The liquid or gyle so prepared, which should have a specific gravity of about 1,060, is run over a refrigerator to reduce the temperature to about 21° C (70° F), then fermented by "pitching" with yeast. The yeast begins to ferment or attenuate the gyle and is allowed to operate for about 3 days, by which time all the sugar is converted into alcohol and the specific gravity is reduced to 1,005 or lower; the gyle now contains about 6% of alcohol. The yeast is skimmed off and the wash stored until required for acetification; prolonged storage is advantageous. The acetifier is essentially a large vat with a false bottom on which is packed beech twigs, lump pumice stone, corncobs, beechwood shavings, coke, rattan, excelsior, or basket work, previously well cleaned, and through which vinegar has been percolated. The acetic bacilli grow on the twigs and begin to operate when the gyle is sparged or sprinkled over them. The essential conditions are an adequate supply of air and a suitable temperature. The latter is maintained by the reaction itself, and is regulated by the air supply which is obtained by means of holes round the sides of the vat below the false bottom, and is adjusted so that the temperature rises to about 41° C (106° F) at which the acetification is most efficiently effected. The gyle is sprinkled on to the twigs from the top, trickles through the mass and is pumped from the bottom back again, so that a continuous percolation is obtained. Acetification is complete in a fortnight or three weeks as compared with as many months in the slow process. In theory 6% alcohol should yield 7·5% of acetic acid but in practice there is always some loss so that the vinegar coming from the acetifier seldom contains more than about 6% of acid. It appears on the market at various strengths from 4% to 6% or more. Two common sources of disturbance in the acetifier are "mother" and eels. The former is a slimy film, sometimes called "tripe," which gradually forms on the twigs, due to a peculiar so-called zoogloeal condition of the bacteria, which impairs the efficiency of the acetifier so that it ultimately has to be emptied and cleaned out. The vinegar eel is a curious creature resembling a thread worm, which may often be seen near the surface of vinegar which has been exposed to the air. Its presence much reduces the activity of the acetifiers but is not of any physiological importance from the point of view of the consumer.

Special Vinegars.—In addition to wine vinegar and ordinary malt or table vinegar, there are various special kinds. Artificial or wood vinegar is an entirely factitious product, made by diluting acetic acid, manufactured by various synthetic processes, with water and colouring it with caramel; it has neither the food value nor the aroma of the genuine article. Cider vinegar is manufactured on a considerable scale in America and on a small scale in parts of England by processes analogous to that of malt vinegar. Wine vinegar is prepared mainly in France and varies in colour according as red or white wine has been used as the raw material. Spirit vinegar is a product manufactured from diluted alcohol which is acetified and coloured.

The question of a standard for vinegar is a vexed one; in the United States and Australia there is a legal minimum of 4% acetic acid; in England a standard of 4% was suggested by the Local Government Board and is generally enforced.

See C. A. Mitchell, *Vinegar: its Manufacture & Examination* (1927); Brannt, *Vinegar* (1914). (H. E. C.)

VINELAND, a borough of Cumberland county, New Jersey, U.S.A., 35 m. S. of Philadelphia; served by the Central of New Jersey and the Pennsylvania railways. Pop. (1920) 6,799. It has an area of 1 sq.m., laid out in unusually broad streets, straight

and well shaded. The surrounding country is devoted largely to fruit, poultry and sweet potatoes, and the borough has a great variety of manufacturing industries. It is the seat of the New Jersey training school for backward children (1888), the State Home for the care and training of feeble-minded women (1888) and the State Home for disabled soldiers, sailors, marines and their wives. Vineland was founded in 1861 by Charles K. Landis (1835–1900). The village was incorporated in 1880.

VINER, SIR ROBERT (1631–1688), lord mayor of London, was born in Warwick. He was apprenticed in London to his uncle, Sir Thomas Viner (1558–1665), a goldsmith, who was lord mayor of London in 1653–54. Robert became a partner in his business, and was chosen lord mayor in 1674. Sir Robert, who was knighted in 1665, was appointed the king's goldsmith in 1661, and lent large sums of money for the expenses of the state and the extravagances of the court; over £400,000 was owing to him when the national exchequer suspended payment in 1672, and he became bankrupt. He obtained from the state an annuity of £25,000. Viner died at Windsor on Sept. 2, 1688.

See *Viner: a Family History,* published anonymously (1885).

VINET, ALEXANDRE RODOLPHE (1797–1847), French critic and theologian, of Swiss birth, was born near Lausanne on June 17, 1797. He was educated for the Protestant ministry, being ordained in 1819, when already teacher of French language and literature in the gymnasium at Basel; and during the whole of his life he was *littérateur* as well as theologian. His literary criticism brought him into contact with Sainte-Beuve, who recognized his quality. Vinet's *Chrestomathie française* (1829), *Études sur la littérature française au XIXme siècle* (1849–51), and *Histoire de la littérature française au XVIIIme siècle,* together with his *Études sur Pascal, Études sur les moralistes aux XVIme et XVIIme siècles, Histoire de la prédication parmis les Réformés de France* and other works, show wide knowledge, moral seriousness, and a fine faculty of appreciation.

As theologian he gave a fresh impulse to Protestantism especially in French-speaking lands, but also in England and elsewhere. Lord Acton classed him with Rothe. He built all on conscience, as that wherein man stands in direct personal relation with God, and as the seat of a moral individuality which nothing can rightly infringe. Hence he advocated complete freedom of religious belief, and to this end the formal separation of Church and State, in his *Mémoire en faveur de la liberté des cultes* (1826), *Essai sur la conscience* (1829), *Essai sur la manifestation des convictions religieuses* (1842). Accordingly, when in 1845 the civil power in the canton of Vaud interfered with the church's autonomy, he led a secession which took the name of *L'Église libre.* A considerable part of his works was not printed till after his death at Clarens, May 4, 1847. They were re-edited with notes by Ph. Bridel in 1912 (Lausanne).

His life was written in 1875 by Eugène Rambert, who re-edited the *Chrestomathie* in 1876. *See* also L. M. Lane, *Life and Writings of A. Vinet* (1890); L. Molines, *Étude sur Alexandre Vinet* (Paris, 1890); V. Rivet, *Études sur les origines de la pensée religieuse de Vinet* (Paris, 1896); A. Schumann, *Alex. Vinet* (1907); E. A. L. Seillière, *A. Vinet, historien de la pensée française* (1925). A uniform edition of his works dates from 1908. (J. V. B.)

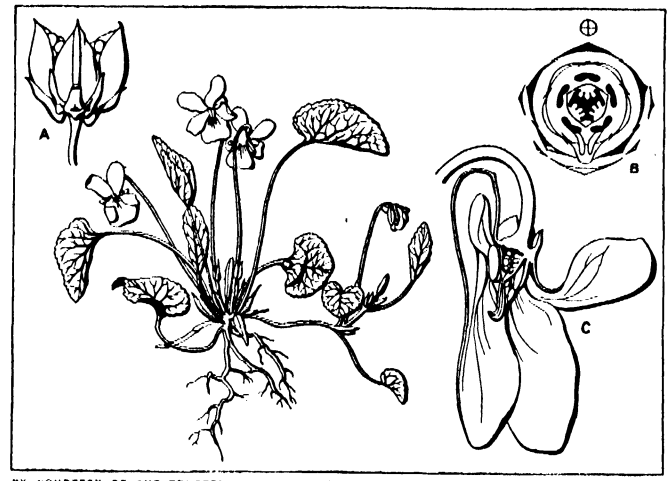
VINGT-ET-UN (colloquially, "Van John"), a round game of cards, at which any number of persons may play, though five or six are enough. The right to deal having been decided, the dealer gives one card face downwards to each person, including himself. The others thereupon look at their cards and declare their stakes—one, two, three or more counters or chips—according to the value of their cards. When all have staked, the dealer looks at his own card and can double all stakes if he chooses. The amount of the original stake should be set by each player opposite his card. Another card is then dealt, face downwards, all round; each player looking at his own. The object of the game is to make 21, by the pips on the cards, an ace counting as 1 or 11, and the court cards as 10 each. Hence a player who receives an ace and a ten-card scores 21 at once. This is called a "natural"; the holder receives twice—sometimes thrice—the stake or the doubled stake. If the dealer has a natural too, the usual rule is that the other natural pays nothing, in spite of the rule of "ties pay the dealer." The deal passes to the player who turns up the natural, unless it occurs in the first round of a deal or the dealer has a natural too. If the dealer has not a natural, he asks each player in turn, beginning with the player on his left, if he wishes for another card or cards, the object still being to get to 21, or as near up to it as possible. The additional cards are given him one by one, face upwards, though the original cards are not exposed. If he requires no additional card, or when he has drawn sufficient, he says, "Content," or "I stand." If a player overdraws, *i.e.*, if his cards count more than 21, he pays the dealer at once. When all are either overdrawn or content, the dealer may "stand" on his own hand, or draw cards, till he is overdrawn or stands. All the hands are then shown, the dealer paying those players whose cards are nearer to 21 than his own, and receiving from *all* the others, as "ties pay the dealer." If the dealer's cards, with the additions, make exactly 21, he receives double the stake, or doubled stake; if a player holds 21, he receives double likewise, but ties still pay the dealer. If a player receives two similar cards he *may* put his stake on each and draw on them separately, receiving or paying according as he stands successfully or overdraws, but the two cards must be similar, *i.e.*, he cannot draw on both a knave and a queen, or a king and a ten, though their values are equal for the purpose of counting. A natural drawn in this way, however, only counts as 21, and does not turn out the dealer. Similarly a player may draw on three cards, or even four, should they be dealt him. A player who overdraws on one of such cards must declare and pay immediately, even though he stands on another. After a hand is played, the "pone" (Latin for "behind")—the player on the dealer's right—collects and shuffles the cards played, the dealer dealing from the remainder of the pack, till it is exhausted, when he takes the cards the pone holds, after the pone has cut them. It is a great advantage to deal. (W. Da.)

VINITA, a city of north-eastern Oklahoma, U.S.A., on federal highways 66 and 73, and served by the Frisco and the Missouri-Kansas-Texas railways; county seat of Craig county. Pop. (1920) 5,010. Vinita is the trade centre and shipping point of a farming, dairying, stock-raising, and fruit-growing region. It has a creamery and a canning factory. The city was founded in 1870 and chartered in 1898.

VINLAND or **WINELAND.** This was the southernmost of the countries discovered by Leif Ericson (*q.v.*) on his voyage from Norway to Greenland in the year 1000, and it was later visited by Thorfinn Karlsefni (*q.v.*), probably in 1004. (*See* also AMERICA: *Pre-Columbian discoveries.*) It derived its name from the wild grapes which the discoverer found there. It is first mentioned in writing by Adam of Bremen (*q.v.*) in his description of the northern countries, about 1075, his informant being King Svein Estridsson of Denmark. The fullest information about this country, as well as about these voyages in general is to be found in the *Saga of Eric the Red* and the *Tale of the Greenlanders.* All these sources agree as to the general characteristics of the country: wild grapes, self-sown wheat, and very mild winter. In some Icelandic writings the name Vinland the Good occurs, and this led Dr. Fridtjof Nansen to assume that the story about Vinland was merely a transformation of the old legends about the Isles of the Blest (*q.v.*). His arguments have not been generally accepted, although it is possible that the epithet "the good" may have later been added under the influence of these legends. The historicity of the discovery can hardly be disputed, nor that Vinland was a part of the American continent, but more definite location is difficult. If we are to accept the account of the wild grapes as authentic, the location of Vinland must fall within the northern limits for this plant which, on the Atlantic coast, are generally put at Passamaquoddy bay. Of the principal writers who have dealt with the problem, C. C. Rafn placed Vinland round Mount Hope bay, in the State of Rhode Island, Gustav Storm in Nova Scotia, where the existence of wild grapes is, however, doubtful. W. H. Babcock and W. Hovgaard have practically reverted to Rafn's view, while G. M. Gathorne-Hardy looks for it at the mouth of the Hudson river.

For bibliography of the subject *see* the articles on AMERICA, *Pre-Columbian Discoveries,* and LEIF ERICSON. (H. He.)

VINOGRADOFF, SIR PAUL GAVRILOVICH (1854–1925), Anglo-Russian scholar, was born at Kostromo, near Moscow, and educated at the University of Moscow. As a young man he travelled widely, and obtained a working knowledge of at least seven modern languages, before being appointed a professor in his own university. He then interested himself in the Zemstvo movement, and sought to improve the provision for the education of the Russian people. His activities, however, were displeasing to the authorities; consequently he resigned his professorship and in 1902 settled in England, where he had already made friends with many English scholars. In 1903 he was appointed Corpus professor of jurisprudence at Oxford, and there he remained until his death on Dec. 19, 1925.



Vinogradoff's first book was on *The Origin of Feudalism in Italy* (1887). This was written in Russian, but his later works were appropriately written in English, and he became recognized as probably the first authority on the early laws and customs of England. His standard work is *Villeinage in England* (1892), in which he put forward the theory that the Anglo-Norman manor descended not from a condition of serfdom, but from a free village community. His article "Folkland," published in *The English Historical Review* in 1893, enunciated an entirely new theory on this subject. His other works include: *English Society in the Eleventh Century* (1908); *The Growth of the Manor* (1905); *Roman Law in Mediaeval Europe* (1909); *Self-government in Russia* (1915) and *Outlines of Historical Jurisprudence* (1920–22). He also contributed to the *Encyclopædia Britannica* and *The Cambridge Modern History*.

VINTON, FREDERIC PORTER (1846–1911), American portrait painter, was born at Bangor, Maine, on the 29th of January 1846. He was a pupil of Duveneck, of William M. Hunt in Boston, of Léon Bonnat and Jean Paul Laurens in Paris, and of the Royal Academy of Munich. In 1891 he was elected a full member of the National Academy of Design, New York. He died in Boston, Mass., May 19, 1911.

VIOL, a generic term for the bowed precursors of the violin (*q.v.*), but in England more specially applied to those immediate predecessors of the violin which are distinguished in Italy and Germany as the *Gamba* family. The chief characteristics of the viols were a flat back, sloping shoulders, "c"-shaped sound-holes, and a short finger-board with frets. All these features assumed different forms in the violin, which was derived rather from the guitar-fiddle than from the viol, the back becoming delicately arched, the shoulders reverting to the rounded outline of the guitar, the shape of the sound-holes changing from "c" to "*f*" and the finger-board being carried considerably nearer the bridge. The viol family consisted of treble, alto, tenor and bass instruments, being further differentiated as *da braccio* or *da gamba* according to the positions in which they were held, against the arm or between the knees.

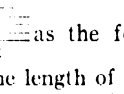
VIOLA, a member of the violin family standing in point of size between the violin and the violoncello. It is known variously as the tenor and the alto member of the family, the latter term obtaining in France and Italy and being derived from the fact that in earlier days, before the full development of the violin, the highest part was usually assigned to it. Having regard to its pitch moreover, which is a fifth below that of the violin, the term seems equally appropriate, the violoncello being then regarded as the real tenor of the family, with the violin and the double-bass completing the quartet as the treble and the bass respectively. To which it may be added that alto was originally the true and only name of the viola, there having been then another and a larger instrument, now obsolete, which was known as the tenor. Apart from its greater size, the construction of the viola is the same as that of the violin. Its tone lacks the brilliance and incisiveness of the latter, being much more dark and veiled in quality, and for this reason it is less effective as a solo instrument than the violin. But it is capable of producing fine results when played by a master, while in the orchestra and in chamber music it is invaluable. For full discussion of instruments of the violin family *see* VIOLIN.

VIOLET. The violets comprise a large botanical genus (*Viola*), in which about 250 species have been described, found principally in temperate or mountain regions of the Northern Hemisphere; they also occur in mountainous districts of South America and South and Tropical Africa, while a few are found in Australasia. The species are mostly low-growing herbs with alternate leaves provided with large leafy stipules. The flowers, which are solitary, or rarely in pairs, at the end of slender axillary flower-stalks, are very irregular in form, with five sepals

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY) (A, B & C). FROM CHURCH, "TYPES OF FLORAL MECHANISM" (CLARENDON PRESS)

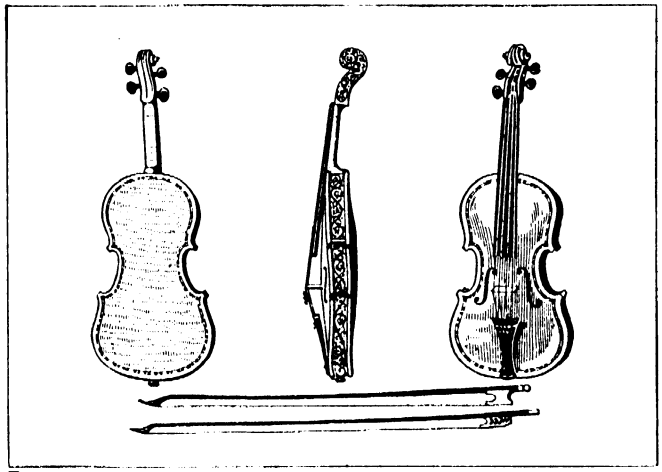
VIOLET (VIOLA ODORATA), SHOWING WHOLE PLANT
A. Fruit. B. Floral diagram. C. Longitudinal section through flower

prolonged at the base, and five petals, the lowest one larger than the others and with a spur, in which collects honey. The irregular construction of the flower is connected with fertilization by insect agency. (*See* POLLINATION.) In the sweet violet (*V. odorata*) and other species, inconspicuous permanently closed or "cleistogamic" flowers occur of a greenish colour, so that they offer no attractions to insect visitors and their form is correspondingly regular; they are self-pollinated. (*See* POLLINATION.)



Several species of *Viola* are native to Great Britain. *Viola canina* is the dog violet, many forms or subspecies of which are recognized; *V. odorata*, sweet violet, is highly prized for its fragrance, and in cultivation numerous varieties have originated. Other species known in gardens are: *V. altaica*, flowers yellow or violet with yellow eye; *V. biflora*, a pretty little species 3 to 4 in. high with small yellow flowers, the large petal being streaked with black; *V. calcarata*, flowers light blue or white, or yellow in var. *flava*; *V. cornuta*, flowers pale blue—there are a few good varieties of this, including one with white flowers; *V. cucullata*, a free-flowering American species with violet-blue or purple flowers; *V. Munbyana*, a native of Algeria, with large violet or yellow flowers; *V. pedata*, the bird's-foot violet, with pedately divided leaves and usually bright blue flowers. The garden pansies or heartseases are derivatives from *V. tricolor*, a cornfield weed, or *V. altaica*, a native of the Altai mountains. (*See* PANSY.)

About 75 species of *Viola* are native to North America, of which about 50 occur from the Rocky Mountains eastward, and the remainder chiefly on the Pacific coast. They are all herbaceous and fall into two general groups: (1) the leafy-stemmed and (2) the stemless violets. While the distinctive characters in many species are sharply marked, the determination of numerous others is very difficult, because of the profusion of natural hybrids. These hybrids were made the subject of intensive experimental study by E. V. Brainerd.



Representative North American violets are the bird's-foot violet (*V. pedata*), the early blue violet (*V. palmata*), the bog blue violet (*V. cucullata*), the arrow-leaved violet (*V. sagittata*), the meadow blue violet (*V. papilionacea*), the southern wood violet (*V. villosa*), the striped violet (*V. striata*), the sweet white violet (*V. blanda*), the beaked violet (*V. rostrata*), the Canada violet (*V. canadensis*), the round-leaved violet (*V. rotundifolia*) and the hairy yellow violet (*V. pubescens*), of the eastern States and Provinces; the prairie yellow violet (*V. Nuttallii*), of the Great Plains region; and the pine violet (*V. lobata*), the mountain violet

(*V. purpurea*), the yellow pansy (*V. pedunculata*), the western heart's-ease (*V. ocellata*) and the wood violet (*V. sarmentosa*) of the Pacific coast. Numerous species are transplanted.

For further details regarding the North American species *see* E. P. Brainerd, "Violets of North America," *Vermont Agric. Exper. Sta. Bull. 224* (1921) and "Some Natural Violet Hybrids of North America," *ib. Bull. 239* (1924).

VIOLIN, the smallest and highest-pitched of one of the most important families of stringed musical instruments, to which it gives its name. It consists essentially of a resonant box of peculiar form, over which four strings of different thicknesses are stretched across a bridge standing on the box in such a way that the tension of the strings can be adjusted by means of revolving pegs, to which they are severally attached at one end. The strings are tuned, by means of the pegs, in fifths, from the second or A string, which is tuned to a fundamental note of about 435 vibrations per second at the modern normal pitch, thus giving  as the four open notes. To produce other notes of the scale the length of the strings is varied by "stopping" them—*i.e.*, pressing them down with the fingers—on a finger-board, attached to a "neck" at the end of which is the "head" in which the pegs are inserted. The strings are set in vibration by drawing across them a bow strung with horse-hair, which is rosined to increase adhesion.

The characteristic features which, in combination, distinguish the violin (including in that family name its larger brethren the viola and violoncello, and in a lesser degree the double-bass) from other stringed instruments are the restriction of the strings to four, and their tuning in fifths; the peculiar form of the body, or resonating chamber, especially the fully moulded back as well as front, or belly; the shallow sides or "ribs" bent into characteristic curves; the acute angles of the corners where the curves of the ends and middle "bouts" or waist ribs meet; and the position and shape of the sound-holes, cut in the belly. By a gradual process of development in all these particulars the modern violin was evolved from earlier bowed instruments, and attained its highest perfection at the hands of the great Italian makers in the 16th, 17th and early 18th centuries, since which time, although many experiments have been made, no material improvement has been effected upon the form and mode of construction then adopted.

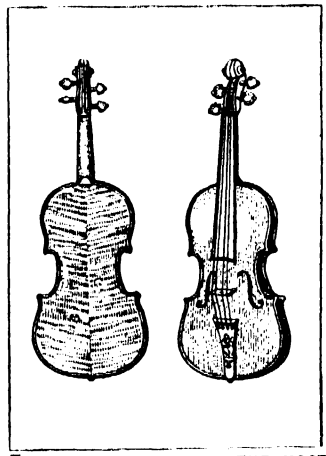
THE "HELLIER" STRADIVARI, DATED 1679, DISTINGUISHED BY ITS ELABORATE INLAID ORNAMENTATION AND SLIGHTLY LARGER AND HEAVIER THAN THE MASTER'S OTHER MODELS

The following are the exact principal dimensions of a very fine specimen of Stradivari's work, which has been preserved in perfect condition since the latter end of the 17th century:—

Length of body	14in. full.
Width across top	$6\frac{1}{16}$in. bare.
Width across bottom	$8\frac{1}{4}$in.
Height of sides (top)	$1\frac{3}{16}$in.
Height of sides (bottom)	$1\frac{7}{32}$in.

The back is in one piece, supplemented a little in width at the lower part, after a common practice of the great makers, and is cut from very handsome wood; the ribs are of the same wood, while the belly is formed of two pieces of soft pine of rather fine and beautifully even grain. The sound-holes, cut with perfect precision, exhibit much grace and freedom of design. The scroll, which is very characteristic of the maker's style and beautifully modelled, harmonizes admirably with the general modelling of the instrument. The model is flatter than in violins of the earlier period, and the design bold, while displaying all Stradivari's microscopic perfection of workmanship. The whole is coated with a very fine orange-red-brown varnish, untouched since it left the maker's hand in 1690, and the only respects in which the instrument has been altered since that date are in the fitting of the longer neck and stronger bass-bar necessitated by the increased compass and raised pitch of modern violin music.

Acoustic Principles.—The acoustics of the violin are extremely complex. Certainly so far as the elementary principles which govern its action are concerned, it follows sufficiently familiar laws (*see* SOUND). The different notes of the scale are produced by vibrating strings differing in weight and tension, and varying in length under the hand of the player. The vibrations of the strings are conveyed through the bridge to the body of the instrument, which fulfils the common function of a resonator in reinforcing the notes initiated by the strings. So far first principles carry us at once. But when we endeavour to elucidate in detail the causes of the peculiar character of tone of the violin family, the great range and variety in that character obtained in different instruments, the extent to which those qualities can be controlled by the bow of the player, and the mode in which they are influenced by minute variations in almost every component part of the instrument, we find ourselves faced by a series of problems which have so far defied any but very partial solution.



The distinctive quality of the musical tones of the violin is generally admitted to be due largely to its richness in the upper harmonic or partial tones superimposed on the fundamental notes produced by the simple vibrations of the strings. The characteristic tone and its control by the player are undoubtedly conditioned in the first place by the peculiar response of the vibrating string under the action of the rosined bow. This takes the form not of a symmetrical oscillation but of a succession of alternating bound and free movements, as the string adheres to the bow according to the pressure applied, and, releasing itself by its elasticity, rebounds. The lightness of the material of which the strings are made conduces to the production of very high upper partial tones which give brilliancy of sound, while the low elasticity of the gut causes these high constituents to be quickly damped, thus softening the ultimate quality of the note.

In order that the resonating body of the instrument may fulfil its purpose in reinforcing the complex vibrations set up by the strings, it is essential that the plates, and consequently the body of air contained between them, should respond sensitively to the selective impulses communicated to them, and it is the attainment of this perfect selective responsiveness which marks the construction of the best instruments. Many factors contribute to this result—the thickness of the plates in different parts of their areas, the size and form of the interior of the body, the size and shape of the sound-holes through which the vibrations of the contained air are communicated to the external air, and which also influence the nodal points in the belly, according to the number of fibres of the wood cut across, varying with the angle at which the sound-holes cross the grain of the wood. And all these important factors are influenced by the quality and elasticity of the wood employed.

Old Instruments' Superiority.—Many speculations have been advanced with regard to the superiority in tone of the old Italian instruments over those of modern construction. After taking into account the practical identity in dimensions and construction between the classical and many of the best modern models, the conclusion suggests itself that the difference must be attributed in part to the nature of the materials used and in part to the method of their employment as influenced by local conditions and practice. The argument, not infrequently advanced, that the great makers of Italy had special local sources of supply can

hardly be sustained. Undoubtedly they exercised great care in the selection of sound and handsome wood; but there is evidence that some of the finest wood they used was imported from across the Adriatic in the ordinary course of trade; and the matter was for them, in all probability, largely one of expense. There is good reason to suppose, indeed, that a far larger choice of equally good material is accessible to modern makers.

There remains the varnish with which the completed instrument is coated. This was an item in the manufacture which received most careful attention at the hands of the great makers, and much importance has been attached to the superiority of their varnish to that used in more recent times—so much so that its composition has been attributed to secret processes known only to themselves. But that the Italian makers individually or collectively attempted, or were able, to preserve as a secret the composition of the varnish they used is unlikely. Instruments exhibiting similar excellence in this respect were too widespread in their range, both of period and locality, to justify the assumption that the general composition of the finest varnish of the early makers was not a matter of common knowledge in an industry so flourishing as that of violin-making in the 17th and early 18th centuries.

THE "ALARD," ONE OF THE MOST FAMOUS OF STRADIVARI'S VIOLINS, MADE IN 1715

The excellence of an instrument in respect of its varnish depended on the quality of the constituent materials, on the proportions in which they were combined, and, perhaps mainly, on the method of its application. The most enduring and perfect varnish used for violins is an oil varnish, and the best results therewith can only be obtained under the most advantageous conditions for the drying process. In this respect there can be no doubt that the southern climate placed the makers whose work lies in higher latitudes at a disadvantage. In a letter to Galileo in 1638 concerning a violin which he had ordered from Cremona, the writer states that "it cannot be brought to perfection without the strong heat of the sun"; and all recorded experience indicates the great importance of slow drying of the varnish under suitable conditions. Stradivari himself wrote to account for delay in the delivery of an instrument because of the time required for the drying of the varnish.

That a perfect varnish conduces to the preservation of a fine tone in the instrument is generally admitted; and its operation in this respect is due, not merely to the external protection of the wood from deterioration, but especially to its action, when applied under favourable conditions to wood at a ripe stage of seasoning (when that process has proceeded far enough, but not so far as to allow the fibres to become brittle), in soaking into the pores of the wood and preserving its elasticity. This being so, successful varnishing will be seen to be an operation of great delicacy, and one in which the old masters found full scope for their skill and large experience. It seems not unreasonable to conclude, therefore, that the varnish of the old instruments contributed probably the most important single element of their superiority in tone.

History.—The immediate ancestors of the violins were the viols, which were the principal bowed instruments in use from the end of the 15th to the end of the 17th century, during the latter part of which period they were gradually supplanted by the violins; but the bass viol did not go out of use finally until towards the later part of the 18th century, when the general adoption of the larger pattern of violoncello drove the viol from the field which it had occupied so long. The sole survivor of the viol type of instrument, although not itself an original member of the family, is the double bass of the modern orchestra, which retains many of the characteristic features of the viol, notably the flat back, with an oblique slope at the shoulders, the high bridge and deep ribs.

Excepting the marine trumpet or bowed monochord, we find in Europe no trace of any large bowed instruments before the appearance of the viols, the bowed instruments of the middle ages being all small enough to be rested on or against the shoulder during performance. The viols probably owe their origin directly to the minnesinger fiddles, which possessed several of the typical features of the violin, as distinct from the guitar family, and were sounded by a bow. These in their turn may be traced to the "guitar fiddle" (*q.v.*), a bowed instrument of the 13th century.

The parentage of the fiddle family may safely be ascribed to the rebec, a bowed instrument of the early middle ages, with two or three strings stretched over a low bridge, and a pear-shaped body pierced with sound-holes, having no separate neck, but narrowed at the upper end to provide a finger-board, and (judging by pictorial representations, for no actual example is known) surmounted by a carved head holding the pegs, in a manner similar to that of the violin. The bow, which was short and clumsy, had a considerable curvature.

So far it is justifiable to trace back the descent of the violin in a direct line; but the earlier ancestry of this family is largely a matter of speculation. The best authorities are agreed that stringed instruments in general are mainly of Asiatic origin, and there is evidence of the mention of bowed instruments in Sanskrit documents of great antiquity. Too much genealogical importance has been attached by some writers to similarities in form and construction between the bowed and plucked instruments of ancient times. They probably developed to a great extent independently, and the bow is of too great and undoubted antiquity to be regarded as a development of the plectrum or other devices for agitating the plucked string. The two classes of instrument no doubt were under mutual obligations from time to time in their development.

From Viol to Violin.—The viol was made in three main kinds, similar to the cantus, medius and bassus of vocal music. Each of these three kinds admitted of some variation in dimensions, especially the bass, of which three distinct sizes ultimately came to be made—(1) the largest, called the concert bass viol; (2) the division or solo bass viol, usually known by its Italian name of viola da gamba; and (3) the lyra or tablature bass viol. The earliest use of the viols was to double the parts of vocal concerted music; they were next employed in special compositions for the viol trio written in the same compass; and finally they were employed as solo instruments, the methods of composition and execution being based on those of the lute. Most lute music is in fact equally adapted for the bass viol, and vice versa. Subsequently the viols were further developed structurally, such instruments as the quinton and the viola d'amore resulting.

The chief defect of the viols was their weakness of tone; this the makers thought to remedy in two ways: first by additional strings in unisons, fifths and octaves; and secondly by sympathetic strings of fine steel wire, laid under the finger-board as close as possible to the belly, and sounding in sympathy with the notes produced on the bowed strings. This system of reinforcement was applied to all the various sizes of viols.

The improvements which resulted in the production of the violin proceeded on different lines. They consisted in increasing the resonance of the body of the instrument, by making it lighter and more symmetrical, and by stringing it more lightly. These changes transformed the body of the viol into that of the violin, and the transformation was completed by rejecting the lute tuning with its many strings, and tuning the instrument by fifths, as the fiddle had been tuned. The tenor viol appears to have been the first instrument in which the change was made, and thus the viola or tenor may probably be claimed as the father of the modern violin family.

The viola and violoncello are made on the same general model and principles as the violin, but with modifications. Both are, relatively to their pitch, made in smaller proportions than the violin, because, if they were constructed to dimensions having the same relation to pitch and tension of strings as the violin, they would not only have an overpowering tone but would be unmanageable from their size. These relatively-diminished dimensions, both in the size of the instrument and in the thickness of the wood and

strings, give to the viola and violoncello a graver and darker quality of tone. To some extent the reduced size is compensated by giving them a greater proportional height in the ribs and bridge; an increase hardly perceptible in the viola but very noticeable in the violoncello. To lighten the tension and thus allow greater freedom of vibration to the belly on the bass side, as with the lowest string of the violin, the two lowest of the viola and violoncello are made of thin gut, covered with fine metal wire, thus providing the necessary weight without inconvenient thickness.

Many other instruments of the violin family, of various sizes and designs, and correspondingly different pitch and tuning, have existed at various times, such as the viola pomposa (a kind of small violoncello invented by Bach), the violoncello piccolo (an instrument half the size of the ordinary violoncello), the arpeggione or guitar violoncello (a six stringed instrument for which Schubert wrote a sonata), the cellone (a deeper violoncello) and the octobass (a deeper doublebass), but all of these are now obsolete. None the less others continue to make their appearance from time to time, no fewer than six, designed to fill supposed gaps in the existing quartet, having been invented within recent years by a French violin maker, Léo Sir.

Makers.—As regards makers, the early Italian school is chiefly represented by the Brescian makers, Gaspar da Salò, Giovanni Paolo Maggini, Giovita Rodiani and Zanetto Peregrino. It is, however, somewhat misleading to denominate it the Brescian school, for its characteristics are shared by the earliest makers of Cremona and Venice. To eyes familiar with the geometrical curves of the later Cremona school, most of the violins of these makers have a rude and uncouth appearance. The height of the model varies; the pattern is attenuated; the *f*-holes share the general rudeness of design, and are set high in the pattern. Andreas Amati of Cremona, the eldest maker of that name, effected some improvements on this primitive model; but the violin owes most to his sons, Antonio and Geronimo, who were partners. They introduced the substantial improvements which developed the Brescian violin into the modern instrument. Nicholas Amati (1596–1684), son of Geronimo, made some slight further improvements and his pupil Antonio Stradivari (1644–1737) finally settled the typical Cremona pattern, which has been generally followed ever since. Only less famous than the last named is Giuseppe Guarnieri (del Jesù) one of several makers of the same name (wherefore the distinguishing "del Jesù") whose instruments if less carefully finished than those of Stradivari are remarkable for the boldness of their design and their powerful tone, so that the finest of them have been preferred by some of the great players to those of Stradivari himself. Paganini among others habitually played on one.

Among non-Italian makers a high model was adopted by Jacob Stainer of Absam, near Hall in Tirol, whose well-known pattern was chiefly followed by the makers of England, Tirol and Germany, down to the middle of the 18th century, when it fell into disuse, owing to the superior musical qualities of the Cremona violin. The English makers may be divided into three successive groups (1) an antique English school, having a character of its own (Rayman, Urquhart, Pamphilon, Barak, Norman, Duke, of Oxford, etc.); (2) imitators of Stainer, at the head of whom stands Peter Wamsley (Smith, Barrett, Cross, Hill, Aireton, Norris, etc.); (3) a later school which leaned to the Cremona model (Banks, Duke of Holborn, Betts, the Forsters, Gilkes, Carter, Fendt, Parker, Harris, Matthew Hardie, of Edinburgh, etc.). The early French makers have little merit or interest (Bocquay, Gavinies, Pierray, Guersan, etc.), but the later copyists of the Cremona models (Lupot, Aldric, Chanot the elder, Nicholas, Pique, Silvestre, Vuillaume, etc.) produced admirable instruments, some of which rank next in merit to the first-rate makers of Cremona.

VIOLLET-LE-DUC, EUGENE EMMANUEL (1814–1879), French architect and writer on archaeology, was born in Paris on Jan. 21, 1814 and died at Lausanne on Sept. 17, 1879. He was a pupil of Achille Leclère, and in 1836–37 studied Greek and Roman architecture in Sicily and Rome. His chief interest was in the art of the Gothic period, and he was employed to restore some of the chief mediaeval buildings of France, his earliest works of restoration being the abbey church of Vézelay, St. Michel at Carcassonne, the church of Semur in Côte-d'Or, and the Gothic town halls of Saint-Antonin and Narbonne, between 1840 and 1850. From 1845 to 1856 he restored Notre Dame in Paris in conjunction with Lassus, and the abbey of St. Denis; in 1849 he began the restoration of the fortifications of Carcassonne and of Amiens cathedral.

As a writer on mediaeval architecture and the kindred arts he takes the highest rank. His two great dictionaries are the standard works in their class, and are most beautifully illustrated.

His principal literary works were the *Dictionnaire de l'architecture française du XI. au XVI. siècle* (1854–68); *Dictionnaire du mobilier français* (1858–75); *L'Architecture militaire au moyen âge* (1854); *Entretiens sur l'architecture* (1863–72); *Cités et ruines américaines* (1863); *Mémoire sur la défense de Paris* (1871); *Habitations modernes* (1874–77); *Histoire d'une maison* (1873); *Histoire d'une forteresse* (1874); *Histoire de l'habitation humaine* (1875); *Le Massif du Mont Blanc* (1876); *L'Art russe* (1877); *Histoire d'un hôtel-de-ville et d'une cathédrale* (1878); *La Décoration appliquée aux édifices* (1879). *See* P. Gout, *Viollet-le-Duc* in *Revue de l'Art Chrétien* Supplements III. (1914); A. Fontainas and G. Gromont, *Histoire Générale de l'Art Français*, vol. ii. (1925).

VIOLONCELLO, the third largest member of the violin family, standing midway, therefore, in point of size and pitch between the viola and the double-bass. Although the word violoncello is a diminutive, signifying "small violone," or double-bass, the instrument is really a bass violin, formed on a different model from the violone, which has the sloping shoulders, and flat back of the viol family, whereas those of the violoncello are rounded as in the violin. It may be added that as the word violoncello is a diminutive the adoption of the second half of it, 'cello, as a contraction, is hardly a happy procedure. The violoncello came into existence soon after the violin and took the place of the viola da gamba, or bass viol, which, however, it only supplanted very gradually. Its construction is the same as that of the violin but on a larger scale, the total length of the instrument being 48½in., though the earliest instruments were somewhat larger. Although at first the viola da gamba continued to be preferred by connoisseurs to the violoncello, which was considered suitable only for accompaniment purposes, the violoncello established its superiority in due course and to-day, alike in concerted music and for solo purposes, ranks second only to the violin among the instruments of its class. Its full rich tone lends itself especially to the execution of expressive cantabile passages. (*See* VIOLIN.)

BY COURTESY OF HILL & SONS
THE VIOLONCELLO WHICH SUPERSEDED THE VIOLA DA GAMBA IN THE 18TH CENTURY

VIONVILLE, a village of Lorraine, near Metz, celebrated as the scene of the battle of Vionville (also called Rezonville or Mars-la-Tour), fought on Aug. 16, 1870 between the French and the Germans (*see* METZ and FRANCO-GERMAN WAR).

VIPERS, snakes of the family Viperidae, which is characterised by the presence of poison fangs on a movable upper jaw. The fangs are simply enlarged teeth perforated longitudinally for the passage of the venom and, like those of all other snakes, they are fused to the supporting bones. In this family, however, there are no other teeth on the upper jaw and the bone itself is movable so that the fangs are folded down parallel with the roof of the mouth when not in use.

Venom is secreted by a pair of glands, situated behind the angle of the mouth, and is carried to the fangs by a short duct which

opens close to their base inside a fold of skin (the *vagina dentis*) which surrounds them; within this fold of skin there is also a series of reserve fangs in different stages of development and, should one of the functional fangs be broken, the largest of these reserve teeth moves into its place and becomes fused to the jaw. Vipers, as a rule, are stout sluggish creatures with a broad, flattened head, and lack the large head shields so characteristic of the majority of other poisonous snakes; most of them are terrestrial though there are aquatic, arboreal and burrowing species. A few lay eggs but the majority produce fully developed young.

BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

THE AFRICAN PUFF ADDER (BITIS ARIETANS)

All the viperidae are very poisonous and the bite of most of them is dangerous to man; the toxicity of the venom varies with each species and the virulence of any bite depends, not only on the species of snake responsible for it, but also on the amount of venom injected, the position of the bite and the physical condition of the snake. In composition viperine venom resembles that of the back-fanged Colubrids, rather than that of the cobras and their allies, and its action consists largely in the destruction of the blood corpuscles and vessels.

The family is subdivisible into two well-defined groups:—

(1) **Viperinae.**—The true vipers or adders, confined to the Old World and characterised by the absence of a pit between the nostril and the eye.

The majority of the snakes of this series are terrestrial, though *Atractaspis* of Tropical and South Africa is a genus of small burrowing creatures with enlarged shields on the head; the Night Adders (*Causus*), of the same region, have the head similarly covered. Arboreal forms are represented by *Atheris*, of the forests of tropical Africa, which is equipped with a prehensile tail and is usually green or olive in colour to harmonise with its surroundings. The colours of the terrestrial species, on the other hand, are more frequently shades of grey, brown or black to harmonise with the rocky or sandy localities which they frequent. The Puff Adder (*Bitis arietans*), which occurs throughout the drier areas of Africa, is a sluggish, heavily-built creature which may grow to a length of four or five feet; it is usually pale brown with a series of regular, dark, chevron-shaped cross-bars along the back, a colouring which harmonises so well with sandy soil that many accidents occur through people failing to notice the animal until they actually tread upon it. The Gaboon Viper (*Bitis gabonica*), unlike its relative, is an inhabitant of the forested regions of Africa and exhibits a geometrical "camouflage" colour pattern of blues, reds and yellows. Many desert species show the feature so characteristic of desert-dwelling animals and plants, the development of spines; *Bitis nasicornis* has a pair of horn-like scales on the tip of the snout and *Cerastes cornutus*, the Horned Viper of Egypt and northern Africa, has a prominent spine above each eye. *Cerastes* and *Echis*, the latter found through northern Africa and southern Asia, including India, exhibit a specialisation for desert life not found elsewhere; the scales of the sides are small and have pronounced, serrated ridges which act, through lateral shovelling movements of the body, as scoops to dig up loose sand and throw it onto the creatures' backs, and so enable them to bury themselves completely. In Europe the family is represented by the genus *Vipera* of which the Adder (*V. berus*) is the best known species; it is an inhabitant of the northern countries and is the only venomous serpent in Britain.

In southern Europe an allied species *V. aspis*, is more common, characterised by a "snub-nose" and this feature is even more pronounced in *V. latastei* of the Iberian Peninsula, whilst in *V. ammodytes* of S.E. Europe the tip of the snout is prolonged upwards into a definite scaly appendage. In India the commonest and most dangerous viper is the Daboia or Tic Polonga (*V. russelli*) which reaches a length of 5 feet.

(2) **Crotalinae.**—Pit vipers and rattlesnakes, centred in America but extending into southern Asia and distinguished by the presence of a deep pit on the side of the head between the eye and the nostril.

This pit is lined by scales, similar to those of the rest of the head, and has a rich nerve supply but its function is quite unknown. Two American genera of this series are equipped with a "rattle" on the end of the tail and are more fully described in the article on *Rattlesnake* (*q.v.*). Of the remainder *Agkistrodon* is distinguished by the possession of large shields on the head and is found through S. Asia and Central and N. America; the American species are semi-aquatic, the Cotton Mouth (*A. piscivorus*) rather more so than the Copperhead (*A. mokasen*), but the Asiatic species (including *A. hypnale* of S. India and Ceylon and *A. halys* of the Caspian region) are terrestrial. Also occurring in S.E. Asia are a number of arboreal species of the genus *Trimeresurus*, the commonest and most widely distributed being *T. gramineus*, a bright green creature with a yellow stripe along the flanks and with the tip of the prehensile tail red. In America some of the most dangerous poisonous snakes belong to this family; they include the dreaded Bushmaster (*Lachesis mutus*) which sometimes attains a length of 12 feet, the Fer-de-Lance (*Bothrops atrox*), the Jararaca (*B. jararaca*) and the Jararacussu (*B. jararacussu*), large forms which inhabit the tropical parts of Central and South America.

VIPER'S BUGLOSS (*Echium vulgare*), a hairy herb of the borage family (Boraginaceae), indigenous to Europe, including Great Britain, and western Asia. The flowers are brilliant blue when expanded, but the buds are reddish. Viper's bugloss, called also blue-weed, has become widely naturalized in the United States and Canada, from Nova Scotia to Ontario and Nebraska and southward to North Carolina; in some sections it is a troublesome weed. It prefers dry soil. The genus *Echium* contains about 30 species, all found in Europe.

VIRBIUS, an old Italian divinity, associated with the worship of Diana at Aricia (*see* DIANA). Under Greek influence, he was identified with Hippolytus (q.v.), who after he had been trampled to death by his own horses was restored to life by Asklepios and removed by Artemis to the grove at Aricia, which horses were not allowed to enter. Virbius was the oldest priest of Diana, and the first *Rex Nemorensis*, "king of the grove."

See Virgil, *Aen.*, vii. 761 and Servius, l.c.; Ovid. *Fasti*, iii. 265, vi. 737; *Metam.*, XV. 497; Suetonius, *Caligula*, 35; Strabo V. p. 239; G. Wissowa, *Religion und Kultus der Römer*. (2nd. ed. 1912); J. G. Frazer, *The Golden Bough* (3rd ed.); A. B. Cook, *Zeus* (1925).

VIRCHOW, RUDOLF (1821–1902), German pathologist and politician, was born on Oct. 13, 1821, at Schivelbein, in Pomerania. In 1843 he received an appointment as assistant-surgeon at the Charité Hospital, becoming pro-rector three years later. In 1847 he began to act as *Privatdozent* in the university, and founded with Reinhardt the *Archiv für pathologische Anatomie und Physiologie*, which, after his collaborator's death in 1852, he carried on alone. In 1848 he went as a member of a government commission to investigate an outbreak of typhus in upper Silesia. About this time, having shown too open sympathy with the revolutionary or reforming tendencies, he was for political reasons obliged to leave Berlin and retire to the seclusion of Würzburg, the medical school of which profited enormously by his labours as professor of pathological anatomy. In 1856 he was recalled to Berlin as ordinary professor of pathological anatomy. As director of the Pathological Institute he formed a centre for research whence flowed a constant stream of original work.

Pathology.—Wide as were Virchow's studies, and successful as he was in all, yet the foremost place must be given to his achievements in pathological investigation. In his book on *Cellularpathologie*, published at Berlin in 1858, he established what Lord Lister described as the "true and fertile doctrine that every morbid structure consists of cells which have been derived from pre-existing cells as a progeny." Virchow made many important contributions to histology and morbid anatomy and to the study of particular diseases. The classification into epithelial organs, connective tissues, and the more specialized muscle and nerve, was largely due to him; and he proved the presence of neuroglia in the brain and spinal cord, discovered crystalline haematoidine, and

made out the basic structure of the umbilical cord. Among the books he published on pathological and medical subjects may be mentioned *Vorlesungen über Pathologie,* the first volume of which was the *Cellular-pathologie* (1858), and the remaining three *Die Krankhaften Geschwülste* (1863–67); *Handbuch der speziellen Pathologie und Therapie* (3 vols., 1854–62), in collaboration with other German surgeons; *Vier Reden über Leben und Kranksein* (1862); *Untersuchungen über die Entwicklung des Schädelgrundes* (1857); *Lehre von den Trichinen* (1865); *Ueber den Hunger-typhus* (1868); and *Gesammelte Abhandlungen aus dem Gebiete der öffentlichen Medizin und der Seuchenlehre* (1879).

Anthropology.—Another science which Virchow cultivated with conspicuous success was anthropology. In ethnology he published a volume of essays on the physical anthropology of the Germans, with special reference to the Frisians; and at his instance a census, which yielded remarkable results, was carried out among school children throughout Germany, to determine the relative distribution of blondes and brunettes. His archaeological work included the investigation of lake dwellings and other prehistoric structures; he went with Schliemann to Troy in 1879, fruits of the expedition being two books, *Zur Landeskunde der Troas* (1880) and *Alt-trojanische Gräber und Schädel* (1882); in 1881 he visited the Caucasus, and on his return published *Das Gräberfeld von Koban im Lande der Osseten.*

Politics.—In 1862 Virchow was elected a member of the Prussian Lower House. He was a founder and leader of the Fortschrittspartei, and the expression *Kulturkampf* had its origin in one of his electoral manifestos. For many years he was chairman of the finance committee, and in that capacity was chief founder of the constitutional Prussian Budget system. In 1880 he entered the Reichstag as representative of a Berlin constituency, but was ousted in 1893 by a Social Democrat. In the Reichstag he became the leader of the Opposition, and a vigorous antagonist of Bismarck. In the local and municipal politics of Berlin again he took a leading part, and as a member of the municipal council was largely responsible for the transformation which came over the city in the last thirty years of the 19th century. It was his unceasing efforts that secured for its inhabitants the drainage system, sewage farms and good water-supply.

Of his writings on social and political questions may be mentioned *Die Erziehung des Weibes* (1865); *Ueber die nationale Entwicklung und Bedeutung der Naturwissenschaften* (1865); *Die Aufgaben der Naturwissenschaften in dem neuen nationalen Leben Deutschlands* (1871); *Die Freiheit der Wissenschaft im modernen Staat* (1877), in which he opposed the idea of Haeckel—that the principles of evolution should be taught in elementary schools—on the ground that they were not as yet proved, and that it was mischievous to teach a hypothesis which still remained in the speculative stage.

See *Lives* by Becher (Berlin, 1894) and Pagel (Leipzig, 1906); *Rudolf Virchow als Patholog* by Marchand (Munich, 1902); *Rudolf Virchow als Arzt* by Ebstein (Stuttgart, 1903); *Gedächtnisrede auf R. Virchow* (Berlin, 1903); and *Briefe Virchows an seine Eltern 1839–1864,* by Marie Rabl (Leipzig, 1907). A bibliography of his works was published at Berlin in 1901.

VIRE, a town of north-western France, capital of an *arrondissement* in the department of Calvados, 47 m. S.W. of Caen by rail. Pop. (1926) 5,466. Vire stands on a hill surrounded on three sides by the Vire and crowned by the remains of a 12th-century château. The church of Notre Dame (13th to 15th century), and the picturesque Tour de l'Horloge (13th century), beneath which runs the chief street, are the principal buildings. Vire grew up around a castle built in the 12th century by Henry I. of England, and in the middle ages was one of the important strongholds of Normandy. South-west of the town is the gorge called Vaux-de-Vire, where stood the mill of Olivier Basselin (15th century), the fuller and reputed author of the satiric songs, hence known as "vaudevilles." (*See* BASSELIN, OLIVIER.)

Vire is an important market town, with trade in horses and cattle, and has various small manufactures. It is the seat of a sub-prefect and a tribunal of commerce.

VIRELAY, the title applied to more than one fixed form of verse (*virer,* to turn). Its history and character are very obscure. It may be connected with the Provençal *ley.* Historians agree that it is a modification of the mediaeval *lai;* but no example of the *lai* is known except the following (first printed by Père Mourgues in his *Traité de la Poésie*):

"Sur l'appui du monde Que faut-il qu'on fonde
D'espoir?
Cette mer profonde Et débris féconde
Fait voir
Calme au matin l'onde Et l'orage gronde
Le Soir."

But this seems to be a mere fragment of a virelay, which proceeds by "veering" the two rhymes *ad libitum.* This is the *virelai ancien,* of which examples are rare in recent literature. There is also the *virelai nouveau,* which was used by Alain Chartier in the 15th century. In French the old and popular *Adieu vous dy triste Lyre* is a perfect example; and in English we have one admirable specimen in Austin Dobson's "Good-bye to the Town, good-bye." A so-called Virelay is found among Chaucer's spurious works (Skeat, vii., 448). The New Virelay is written on two rhymes, and begins with two lines that recur throughout as refrains, and (reversed in order) close the poem in a couplet. The Virelay is a vague and invertebrate form of verse, and one of little importance.

VIREO, the common name of birds of the American passerine family *Vireonidae.* There are about 50 species of these insectivorous birds, which have characteristic and often very musical songs. Twelve species inhabit the United States, all building deep, pendent, cup-shaped nests, usually hung between the forks of a branch. The red-eyed vireo (*V. olivaceus*) breeds from the Gulf States to Labrador and British Columbia, wintering in Central and South America. West of the Cascade mountains, it is replaced by Hutton's vireo (*V. huttoni*), with three subspecies, lacking the slate crown of *V. olivaceus.* The warbling vireo (*V. gilvus*) of eastern U.S.A. and Canada has a fine song.

VIRGIL (PUBLIUS VERGILIUS MARO) (70–19 B.C.) the great Roman poet, was born on Oct. 15, 70 B.C., on a farm not far from the town of Mantua. In the region north of the Po a race of more imaginative susceptibility than the people of Latium formed part of the Latin-speaking population. It was favourable to his development as a national poet that he was born and educated during the interval of comparative calm between the first and second Civil Wars, and that he belonged to a generation which, as the result of the Social War, first enjoyed the sense of an Italian nationality. It is remarkable that the two poets whose imagination seems to have been most powerfully possessed by the spell of Rome—Ennius and Virgil—were born outside the pale of Roman citizenship.

Like his friend and contemporary Horace, he sprang from the class of yeomen, whose state he pronounces the happiest allotted to man and most conducive to virtue and piety. At the age of twelve he was taken for his education to Cremona, and from an expression in one of his minor poems it may be inferred that his father accompanied him. Afterwards he removed to Milan, where he continued to study till he went to Rome two years later.

After studying rhetoric he began the study of philosophy under Siron the Epicurean. One of the minor poems written about this time in the scazon metre tells of his delight at the immediate prospect of entering on the study of philosophy; at the end of the poem, the real master-passion of his life, the charm of the Muses, reasserts itself (*Catalepton* v.).

Our next knowledge of him is derived from allusions in the *Eclogues,* and belongs to a period nine or ten years later. Of what happened to him in the interval, during which the first Civil War took place and Julius Caesar was assassinated, we have no indication from ancient testimony or from his own writings. In 42 B.C., the year of the battle of Philippi, we find him "cultivating his woodland Muse" under the protection of Asinius Pollio, governor of the district north of the Po. In the following year the famous confiscations of land for the benefit of the soldiers of the triumvirs took place. Of the impression produced on Virgil by these confiscations, and of their effect on his fortunes, we have a vivid record in the first and ninth eclogues. Mantua, in consequence of its vicinity to Cremona, which had been faithful to the cause of the republic, was involved in this calamity; and Virgil's father was driven from his farm. By the influence of his powerful friends, and by personal application to the young Octavian, Virgil

obtained the restitution of his land. In the meantime he had taken his father and family with him to the small country house of his old teacher Siron (*Catalepton* x.).

Soon afterwards we hear of him living in Rome, enjoying the favour of Maecenas, intimate with Varius, who was at first regarded as the rising poet of the new era, and later on with Horace. His friendship with Gallus, for whom he indicates a warmer affection and more enthusiastic admiration than for any one else, was formed before his second residence in Rome, in the Cisalpine province. The pastoral poems, or "eclogues," commenced in his native district, were finished and published in Rome, probably in 37 B.C. Soon afterwards he withdrew from Rome, and lived chiefly in Campania, either at Naples or in the neighbourhood of Nola. He was one of the companions of Horace in the famous journey to Brundisium; and it seems not unlikely that, some time before 23 B.C., he made the voyage to Athens which forms the subject of the third ode of the first book of the *Odes* of Horace.

The seven years from 37 to 30 B.C. were devoted to the composition of the *Georgics*. In the following year he read the poem to Augustus, on his return from Asia. The remaining years of his life were spent on the composition of the *Aeneid*. In 19 B.C., after the *Aeneid* was finished but not finally corrected, he set out for Athens, intending to pass three years in Greece and Asia and to devote that time to perfecting the poem. At Athens he met Augustus, and was persuaded by him to return with him to Italy. While visiting Megara under a burning sun, he was seized with illness, and, as he continued his voyage without interruption, he grew rapidly worse, and died on Sept. 21, 19 B.C., a few days after landing at Brundisium. In his last illness he called for the cases containing his manuscripts, with the intention of burning the *Aeneid*. He had previously left directions in his will that his literary executors, Varius and Tucca, should publish nothing of his which had not already been given to the world by himself. A passage from a letter of his to Augustus is also quoted, in which he speaks as if he felt that the undertaking of the work had been a mistake. This dissatisfaction with his work may be ascribed to his passion for perfection of workmanship, which death prevented him from attaining. The command of Augustus overrode the poet's wish and rescued the poem.

Virgil was buried at Naples, where his tomb was long regarded with religious veneration. Horace is our most direct witness of the affection which he inspired among his contemporaries. The qualities by which he gained their love were, according to his testimony, *candor*—sincerity of nature and goodness of heart—and *pietas*—the union of deep affection for kindred, friends and country with a spirit of reverence. The statement of his biographer, that he was known in Naples by the name "Parthenias," is a testimony to the exceptional purity of his life in an age of licence. The seclusion of his life and his devotion to his art touched the imagination of his countrymen as the finer qualities of his nature touched the heart of his friends. It had been, from the time of Cicero, the ambition of the men of finest culture and most original genius in Rome to produce a national literature which might rival that of Greece; and the feeling that at last a poem was about to appear which would equal or surpass the greatest among all the works of Greek genius found a voice in the lines of Propertius—

> Cedite Romani scriptores, cedite Graii;
> Nescio quid maius nascitur Iliade.

The veneration in which his name was held between the overthrow of Western civilization and the revival of letters affords testimony of the depth of the impression which he made on the imagination of the ancient world. The traditional belief in his pre-eminence has been on the whole sustained, though not with absolute unanimity, in modern times.

The effect of this was a juster estimate of Virgil's relative position among the poets of the world. Lucretius, it may be thought, was individually the greater poet. But it can hardly be questioned, on a survey of Roman literature, that the position of Virgil is central and commanding, while that of Lucretius is in a great measure isolated. If we could imagine the place of Virgil in Roman literature vacant, it would be much the same as if we imagined the place of Dante vacant in modern Italian, and that of Goethe in German literature.

Virgil's fame as a poet rests on the three acknowledged works of his early and mature manhood—the pastoral poems or *Eclogues*, the *Georgics* and the *Aeneid*—all written in that hexameter verse which Tennyson has called

> The stateliest measure ever moulded by the lips of man.

Eclogues.—The pastoral poems or *Eclogues*—a word denoting short selected pieces—were composed between the years 42 and 37 B.C. His expressed aim is to pay in the Latin language to the Italian countryside the tribute of Theocritus to Sicily.

The earliest poems in the series were the second, third and fifth; and these, along with the seventh, are the most purely Theocritean in character. The first and ninth, which probably were next in order, are much more Italian in sentiment, and have a much more direct reference both to his own circumstances and the circumstances of the time. The first is a reflex of the distress and confusion which arose out of the new distribution of lands. The ninth contains the lines which seem accurately to describe the site of Virgil's farm, at the point where the range of hills which accompany the river Mincio for some distance from the foot of the Lago di Garda sinks into the plain about 14 or 15 m. above Mantua. The sixth is addressed to Varus, who succeeded Pollio as governor of the Cisalpine district. Its theme is the creation of the world, and the oldest tales of mythology. The fourth and eighth are both closely associated with the name of Virgil's earliest protector, Pollio. The fourth celebrates the consulship of his patron in 40 B.C., and also the prospective birth of a child, though it was disputed in antiquity, and still is disputed, who was meant by this child whose birth was to be coincident with the advent of the new era, and who, after filling the other great offices of state, was to "rule with his father's virtues the world at peace." The main purpose of the poem, however, is to express the longing of the world for a new era of peace and happiness, of which the treaty of Brundisium seemed to hold out some definite hopes. Some of the phraseology of the poem led to a belief in the early Christian church that Virgil had been an unconscious instrument of inspired prophecy. The date of the eighth is fixed by a reference to the campaign of Pollio against the Dalmatians in 39 B.C. It brings before us two love tales of homely Italian life. The tenth reproduces the Daphnis of Theocritus, and is a dirge over the unhappy love of Gallus and Lycoris.

There is no important work in Latin literature, with the exception of the comedy of Terence, so imitative as the *Eclogues*. But they are not purely exotic. They are rather composite, partly Greek and partly Italian, and, as a vehicle for the expression of feeling, hold an undefined place between the objectivity of the Greek idyll and the subjectivity of the Latin elegy. For the most part, they express the sentiment inspired by the beauty of the world, and the kindred sentiment inspired by the charm of human relationships. The supreme charm of the diction and rhythm is universally recognized.

Georgics.—It is stated that Maecenas, acting on the principle of employing the poets of the time in favour of the conservative and restorative policy of the new government, directed the genius of Virgil to the subject of the *Georgics*. No object could be of more consequence to a supporter of Augustus' policy leaders than the revival of the great national industry, which had fallen into abeyance owing to the long unsettlement of the revolutionary era as well as to other causes. Virgil's previous life and associations made it natural for him to identify himself with this object, while his genius fitted him to enlist the imagination of his countrymen in its favour. His aim was to describe with realistic fidelity, and to surround with an atmosphere of poetry, the annual round of labour in which the Italian yeoman's life was passed; to bring out the intimate relation with nature into which man was brought in the course of that life, and to suggest the delight to heart and imagination which he drew from it; to contrast the simplicity, security and sanctity of such a life with the luxury and lawless passions of the great world; and to associate the ideal of a life of rustic labour with the beauties of Italy and the glories of Rome. This larger conception of the dignity of his subject separates the

didactic poem of Virgil from all other didactic, as distinct from philosophic, poems. He has produced in the *Georgics* a new type of didactic, as in the *Aeneid* he has produced a new type of epic, poetry.

The subject is treated in four books, varying in length from 514 to 566 lines. The first treats of the tillage of the fields, of the constellations, the rise and setting of which form the farmer's calendar, and of the signs of the weather, on which the success of his labours largely depends. The second treats of trees, and especially of the vine and olive, two great staples of the national wealth and industry of Italy; the third of the rearing of herds and flocks and the breeding of horses; the fourth of bees.

Hesiod Virgil regarded as his prototype; he supplied the outline of the form. The Alexandrian scientific poets provided him with examples for his method of treatment. But a more powerful influence on the form, ideas, sentiment and diction of the *Georgics* was exercised by the great philosophical poem of Lucretius, of which Virgil had probably been a diligent student since the time of its first appearance, and with which his mind was saturated when he was engaged in the composition of the *Georgics*. So far as any speculative idea underlying the details of the *Georgics* can be detected, it is one of which the source can be traced to Lucretius—the idea of the struggle of human force with the forces of nature. In the general plan of the poem Virgil follows the guidance of Lucretius rather than that of any Greek model. The distinction between a poem addressed to national and one addressed to philosophical sympathies is marked by the prominence assigned in the one poem to Caesar as the supreme personality of the age, in the other to Epicurus as the supreme master in the realms of mind. In the systematic treatment of his materials, and the interspersion of episodes dealing with the deeper poetical and human interest of the subject, Virgil adheres to the practice of the older poet.

The *Georgics* is not only the most perfect, but the most native of all the works of the ancient Italian genius. Even where he borrows from Greek originals, Virgil makes the Greek mind tributary to his national design. The *Georgics*, the poem of the land, is as essentially Italian as the *Odyssey*, the poem of the sea, is essentially Greek.

Aeneid.—The work which yet remained for Virgil to accomplish was the addition of a great Roman epic to literature. This had been the earliest effort of the national imagination, when it first departed from the mere imitative reproduction of Greek originals. The work which had given the truest expression to the genius of Rome before the time of Virgil had been the *Annales* of Ennius. This had been supplemented by various historical poems but had never been superseded. It satisfied the national imagination as an expression of the national life in its vigorous prime, but it could not satisfy the newly developed sense of art; and the expansion of the national life since the days of Ennius, and the changed conditions into which it passed after the battle of Actium, demanded a newer and ampler expression. It had been Virgil's earliest ambition to write an heroic poem on the traditions of Alba Longa; and he had been repeatedly urged by Augustus to celebrate his exploits. The problem before him was to compose a work of art on a large scale, which should represent a great action of the heroic age, and should at the same time embody the most vital ideas and sentiment of the hour—which in substance should glorify Rome and the present ruler of Rome, while in form it should follow closely the great models of epic poetry and reproduce all their sources of interest. It was his ambition to be the Homer, as he had been the Theocritus and Hesiod, of his country.

Various objects had thus to be combined in a work of art on the model of the Greek epic: the revival of interest in the heroic foretime; the satisfaction of national sentiment; the expression of the deeper currents of emotion of the age; the personal celebration of Augustus. A new type of epic poetry had to be created. It was desirable to select a single heroic action which should belong to the cycle of legendary events celebrated in the Homeric poems, and which could be associated with Rome. The only subject which in any way satisfied these conditions was that of the wanderings of Aeneas and of his final settlement in Latium. The story, though not of Roman origin but of a composite growth, had long been familiar to the Romans, and had been recognized by official acts of senate and people. The subject enabled Virgil to tell again of the fall of Troy, and to weave a tale of sea-adventure similar to that of the wanderings of Odysseus. It was also recommended by the claim which the Julii, a patrician family of Alban origin, made to descent from Iulus, the supposed son of Aeneas.

The *Aeneid* is thus at once the epic of the national life under its new conditions and an epic of human character. The true keynote of the poem is struck in the line with which the poem closes—

Tantae molis erat Romanam condere gentem.

The idea which underlies the whole action of the poem is that of the great part played by Rome in the history of the world, that part being from of old determined by divine decree, and carried out through the virtue of her sons. The idea of universal empire is thus the dominant idea of the poem. With this idea that of the unbroken continuity of the national life is intimately associated. The reverence for old customs and for the traditions of the past was a large element in the national sentiment, and has a prominent place in the *Aeneid*. So too has the feeling of local attachment and of the power of local association over the imagination. The poem is also characteristically Roman in the religious belief and observances which it embodies. Behind all the conventional machinery of the old Olympic gods there is the Roman apprehension of a great inscrutable power, manifesting itself by arbitrary signs, exacting jealously certain observances, working out its own secret purposes through Roman arms and Roman counsels.

The idealization of Augustus is no expression of servile adulation. It is through the prominence assigned to him that the poem is truly representative of the critical epoch in human affairs at which it was written. The cardinal fact of that epoch was the substitution of personal rule for the rule of the old commonwealth over the Roman world. Virgil shows the imaginative significance of that fact by revealing the emperor as chosen from of old in the counsels of the supreme ruler of the world to fulfil the national destiny, as descendant of gods and heroes of old poetic renown.

Virgil's true and yet idealizing interpretation of the imperial idea of Rome is the basis of the greatness of the *Aeneid* as a representative poem. It is on this representative character and on the excellence of its artistic execution that the claim of the *Aeneid* to rank as one of the great poems of the world mainly rests. The inferiority of the poem to the *Iliad* and the *Odyssey* as a direct representation of human life is so unquestionable that we are in danger of underrating the real though secondary interest which the poem possesses as an imitative epic of human action, manners and character. In the first place it should be remarked that the action is chosen not only as suited to embody the idea of Rome, but as having a peculiar nobleness and dignity of its own. It brings before us the spectacle of the destruction of the city of greatest name in poetry or legend, of the foundation of the imperial city of the western seas, in which Rome had encountered her most powerful antagonist in her long struggle for supremacy, and that of the first rude settlement on the hills of Rome itself. It might be said of the manner of life represented in the *Aeneid*, that it is no more true to any actual condition of human society than that represented in the *Eclogues*. But may not the same be said of all idealizing restoration of a remote past in an age of advanced civilization? The life represented in the *Oedipus Tyrannus* or in *King Lear* is not the life of the Periclean nor of the Elizabethan age, nor is it conceivable as the real life of a prehistoric age. Where Virgil is least real, and most purely imitative, is in the battle-scenes of the later books.

But the adverse criticisms of the *Aeneid* are chiefly based on Virgil's supposed failure in the crucial test of the creation of character. And his chief failure is pronounced to be the "pious Aeneas." Is Aeneas a worthy and interesting hero of a great poem of action? Not, certainly, according to the ideals realized in Achilles and Odysseus, nor according to the modern ideal of heroism. Virgil wishes to hold up in Aeneas an ideal of pious obedience and persistent purpose—a religious ideal belonging to the ages of faith combined with the humane and self-sacrificing qualities belonging to an era of moral enlightenment. His own sympathy

is with his religious ideal rather than with that of chivalrous romance. He felt that the deepest need of his time was not military glory, but peace, reconciliation, restoration of law, and piety.

In Dido Roman poetry has added to the great gallery of men and women, created by the imaginative art of different times and peoples, the ideal of a true queen and a true woman. On the episode of which she is the heroine the most passionate human interest is concentrated. It has been objected that Virgil does not really sympathize with his own creation, that he gives his approval to the cold desertion of her by Aeneas. But if he does not condemn his hero, he sees in the desertion and death of Dido a great tragic issue in which a noble and generous nature is sacrificed to the larger purpose of the gods.

Virgil brought the two great instruments of varied and continuous harmony and of a rich, chastened and noble style to the highest perfection of which the Latin tongue was capable. The rhythm and style of the *Aeneid* is more unequal than the rhythm and style of the *Georgics*, but is a larger and more varied instrument. The note of his supremacy among all the poetic artists of his country is that subtle fusion of the music and the meaning of language which touches the deepest and most secret springs of emotion. He touches especially the emotions of reverence and of yearning for a higher spiritual life, and the sense of nobleness in human affairs, in great institutions and great natures; the sense of the sanctity of human affections, of the imaginative spell exercised by the past, of the mystery of the unseen world. This is the secret of the power which his words have had over some of the deepest and greatest natures in all ages. (W. Y. S.; X.)

BIBLIOGRAPHY.—*Appendix Vergiliana.*—Under this collective name there are current several poems of some little length and some groups of shorter pieces, all attributed to Virgil in antiquity. Virgil wrote a *Culex*, but not the *Culex* now extant, though it passed for his half a century after his death. The *Aetna*, the *Ciris* and the *Copa* are clearly not Virgil's. The *Moretum* is said to have been translated by him from a Greek poem by his teacher Parthenius; it is an exquisite piece of work, familiar perhaps to English readers in Cowper's translation. The case of the *Catalepton* (κατὰ λεπτόν) is peculiar. Two of these little poems (*Ite hinc inanes* and *Villula, quae Sironiseras*) are generally accepted as Virgil's; opinion varies as to the rest, with very little to go upon, but generally rejecting them. The whole are printed in the larger editions of Virgil. For English readers the most obvious edition is that of Robinson Ellis (1907), who has also edited the *Aetna* separately.

Manuscripts.—Gellius (*Noctes Atticae*, ix. 14, 7) tells us of people who had inspected *idiographum librum Vergilii*, but this has of course in all probability long since perished. There are, however, seven very ancient MSS. of Virgil. (1) The Mediceus at Florence, with a note purporting to be by a man, who was consul in 494, to say he had read it. (2) The Palatinus Vaticanus of the 4th or 5th century. (3) The Vaticanus of the same period. (4) The "Schedae Vaticanae." (5) The "Schedae Berolinenses," perhaps of the 4th century. (6) The "Schedae Sangallenses." (7) The "Schedae rescriptae Veronenses" —the last three of insignificant extent. For a fully detailed account of the MSS., *see* Henry, *Aeneidea*, i., and Ribbeck, *Prolegomena ad Verg.*

Ancient Commentators.—Commentaries on Virgil began to be written at a very early date. Suetonius, *V. Verg.* 44, mentions an *Aeneidomastix* of Carvilius Pictor and other works on Virgil's "thefts" and "faults," besides eight "volumina" of Q. Octavius Avitus, setting out in parallel passages the "likenesses" (ὁμοιότητες was the name of the work) between Virgil and more ancient authors. M. Valerius Probus (latter part of 1st century A.D.) wrote a commentary, but it is doubtful for how much of what passes under his name he is responsible, if for any of it. At the end of the 4th century come the commentaries of Tiberius Claudius Donatus and of Servius, the former writing as a teacher of rhetoric, the latter of style and grammar. The work of Servius was afterwards expanded by another scholar, whose additions greatly added to its worth, as they are drawn from older commentators and give us very valuable information on the old Roman religion and constitution, Greek and Latin legends, old Latin and linguistic usages. In this enlarged form the commentary of Servius and the *Saturnalia* of Macrobius (also of the end of the 4th century) are both of great interest to the student of Virgil. There are, further, sets of Scholia in MSS. at Verona and Bern, which draw their material from ancient commentaries. *See* H. Nettleship, *Essays in Latin Literature*, xi. and Comparetti, *Vergil in the Middle Ages* (1875; trans. 1895), ch. 5 (1885; 2nd series, 1895).

Editions.—The editions of Virgil are innumerable; Heyne (1767–1800), Forbiger (1872–75) and Ribbeck (1859–66) in Germany, Benoist (1876) in France, and Conington (completed by Nettleship, and edited by Haverfield, 1898, etc.) in England, are perhaps the most important. Good school editions in English have been produced by Page, Sidgwick and Papillon. Conington's work, however, is without question the best in English.

Translations.—Famous English translations have been made by Dryden and by a host of others since his day. Since the middle of the 19th century the most important are Conington (*Aeneid* in verse, whole works in prose); J. W. Mackail (*Aeneid* and *Georgics* in prose); William Morris (*Aeneid* in verse); Lord Justice Bowen (*Eclogues* and *Aeneid*, i.–vi. in verse); Canon Thornhill (verse); C. J. Billson (verse, 1906); J. Rhoades (verse, new ed., 1907). For essays on translating Virgil, *see* Conington, *Miscellaneous Works*, vol. i.; R. Y. Tyrrell, *Latin Poetry* (appendix).

AUTHORITIES.—For full bibliographies of Virgil consult Schanz, *Gesch. der Römischen Literatur* (1899) (in Iwan von Müller's series, *Handbuch der Klassischen Altertums-Wissenschaft*), and Teuffel, *History of Roman Literature*, edited by L. Schwabe and tr. by G. C. W. Warr (1900). On the life of Virgil: Nettleship's *Ancient Lives of Vergil* (1879) discusses the authorities, printing one of the lives, which he shows to be by Suetonius. On the *Eclogues:* Glaser, *V. als Naturdichter u. Theist* (1880); Cattault, *Étude sur les Bucoliques de V.* (1897). On the *Georgics:* Morsch, *De Graecis in Georgicis a V. expressis* (1878); Norden, "V.-studien" (in *Hermes*, vol. 28, 1893) (Norden has little patience with "aesthetic criticism"). On the *Aeneid:* Schwegler, *Röm. Gesch.* vol. i. (1853); Cauer, *De fabulis Graecis ad Roman conditam pertinentibus;* Hild, *La Légende d'Énée avant V.* (1883); Förstemann, *Zur Gesch. des Aeneasmythus;* H. de la Ville de Mirmont, *Apollonios de Rhodes et Virgile* (1894) (rather too long); Plüss, *V. u. die epische Kunst* (1884); Georgii, *Die politische Tendenz der Aen.* (1880); Boissier, *Nouvelles promenades archéologiques* (1886) (trans. under title *The Country of Horace and Virgil*, by D. Havelock Fisher, 1895); Gibbon, *Critical Observations on the Sixth Book of the Aeneid* (1770); Boissier, *La Religion romaine d'Auguste aux Antonins* (1884) (with section on sixth *Aeneid*); Ettig, *Acheruntica* (Leipziger Studien, 1891); Norden, "V.-studien" (in *Hermes*, vol. 28, 1893), on sixth *Aeneid*, and papers in *Neue Jahrbücher für kl. Altertum* (1901); Dieterich, *Nekyia* (1893) (on Apocalypse of Peter and ancient teaching on the other life—a valuable book); Henry, *Aeneidea* (1873–79) (a book of very great learning, wit, sense and literary judgment; the author, an Irish physician, gave twenty years to it, examining MSS., exploring Virgil's country, and reading every author whom Virgil could have used and nearly every ancient writer who used Virgil).

Virgil-literature: Sainte-Beuve, *Étude sur Virgile* (one of the great books on Virgil); Comparetti, *Virgilio nel medio Evo* (1872)— Eng. tr., *Vergil in the Middle Ages*, by E. F. M. Benecke (1895) (a book of very great and varied interest); Heinze, *Virgil's epische Technik* (1902); W. Y. Sellar, *Roman Poets of the Augustan Age: Virgil* (2nd ed. 1883); Glover, *Studies in Virgil* (1904). Essays in the following: F. W. H. Myers, *Essays [Classical]* (1883), the most famous English essay on Virgil; J. R. Green, *Stray Studies* (1876) (an excellent study of Aeneas); W. Warde Fowler, *A Year with the Birds* (on Virgil's bird-lore); Nettleship, *Essays in Latin Literature* (1884); Tyrrell, *Latin Poetry* (1898); Patin, *Essais sur la poésie Latine* (4th ed. 1900) (one of the finest critics of Latin literature); Goumy, *Les Latins* (1892) (a volume of very bright essays); J. W. Mackail, *Latin Literature* (3rd ed. 1899); H. W. Garrod, *Vergil* (1912); T. Frank, *Vergil. A biography* (1922); J. W. Mackail, *Virgil and his meaning to the world of to-day* (1923).

THE VIRGIL LEGEND

Virgil's great popularity in the middle ages is to be partly explained by the fact that he was to a certain extent recognized by the Church. He was supposed to have prophesied the coming of Christ in the fourth *Eclogue*, and by some divines the *Aeneid* was held to be an allegory of sacred things. This position was sufficiently emphasized by Dante when he chose him from among all the sages of antiquity to be his guide in the *Divina Commedia*. Ancient poets and philosophers were commonly transformed by mediaeval writers into necromancers; and Virgil and Aristotle became popularly famous, not for poetry and science, but for their supposed knowledge of the black art. Naples appears to have been the home of the popular legend of Virgil, which represented him as the special protector of the city, but was probably never quite independent of learned tradition.

One of the earliest references to the magical skill of Virgil occurs in a letter of the imperial chancellor Conrad of Querfurt (1194), reproduced by Arnold of Lübeck in the continuation of the *Chronica Slavorum* of Helmold. John of Salisbury alludes to the brazen fly fabricated by Virgil; Hélinand (d. 1227) speaks of similar marvels in a work from which Vincent of Beauvais has borrowed; and Gervase of Tilbury, in his *Otia Imperialia* (1212), and Alexander of Neckam (d. 1217), in *De Naturis Rerum*, have reproduced these traditions. Many current tales of magic were referred to Virgil, and gradually developed into a completely new life, strangely different from that of the real hero. They were collected in French under the title of *Les Faitz Merveilleux de Virgille* (*c.* 1499), a quarto chapbook of ten pages, which became extremely popular, and was printed, with more or

less additional matter, in other languages. The English version, beginning "This is resonable to wryght the mervelus dedes done by Virgilius," was printed about 1520. We are told how Virgil beguiled the devil at a very early age, in the same fashion as the fisherman persuaded the jinnee in the *Arabian Nights* to re-enter Solomon's casket. Another reproduction of a widely spread tale was that of the lady who kept Virgil suspended in a basket. To revenge the affront the magician extinguished all the fires in the city, and no one could rekindle them without subjecting the lady to an ordeal highly offensive to her modesty. Virgil made for the emperor a castle in which he could see and hear everything done or said in Rome, an ever-blooming orchard, statues of the tributary princes which gave warning of treason or rebellion, and a lamp to supply light to the city. He abducted the soldan's daughter, and built for her the city of Naples upon a secure foundation of eggs. At last, having performed many extraordinary things, he knew that his time was come. In order to escape the common lot he placed all his treasures in a castle defended by images unceasingly wielding iron flails, and directed his confidential servant to hew him in pieces, which he was to salt and place in a barrel in the cellar, under which a lamp was to be kept burning. The servant was assured that after seven days his master would revive, a young man. The directions were carried out; but the emperor, missing his medicine-man, forced the servant to divulge the secret and to quiet the whirling flails. The emperor and his retinue entered the castle and at last found the mangled corpse. In his wrath he slew the servant, whereupon a little naked child ran thrice round the barrel, crying, "Cursed be the hour that ye ever came here," and vanished.

For the legends connected with Virgil *see* especially D. Comparetti, *Virgilio nel medio evo* (2nd ed., Florence, 1896; English trans. E. F. M. Benecke, 1895). The chief original source for the Neapolitan legends is the 14th-century *Cronica di Partenope*. *See* further W. J. Thoms, *Early Eng. Prose Romances* (1858); G. Brunet, *Les Faitz merveilleux de Virgile* (Geneva, 1867); E. Duméril, "Virgile enchanteur" (*Mélanges archéologiques*, 1850); Gervase of Tilbury, *Otia Imper.* (ed. Liebrecht, 1856); P. Schwubbe, *Virgilius per mediam aetatem* (Paderborn, 1852); Siebenhaar, *De fabulis quae media aetate de Virgilio circumf.* (Berlin, 1837); J. G. T. Graesse, *Beiträge zur Lit. u. Sage des Mittelalters* (1850); Bartsch, "Gedicht auf. d. Zaub. Virgil" (Pfeiffer's *Germania*, iv. 1859); F. Liebrecht, "Der Zauberer Virgilius" (ibid. x. 1865); K. L. Roth, "Über d. Zaub. Virgilius" (ibid. iv. 1859); W. Victor, "Der Ursprung der Virgilsage" (*Zeit. f. rom. Phil.* i. 1877); A. Graf, *Roma nella memoria e nelle imaginazioni del medio evo* (Turin, 1882); F. W. Genthe, *Leben und Fortleben des Publius Virgilius Maro als Dichter und Zauberer* (2nd ed., Magdeburg, 1857).

VIRGIL, POLYDORE (*c.* 1470–1555), English historian, of Italian extraction, otherwise known as P. V. CASTELLENSIS, was a kinsman of Cardinal Hadrian Castellensis, a native of Castro in Etruria. His father's name is said to have been George Virgil; his great-grandfather, Anthony Virgil, "a man well skilled in medicine and astrology," had professed philosophy at Paris, as did Polydore's own brother and protégé John Matthew Virgil, at Pavia, in 1517. A third brother was a London merchant in 1511. Polydore was born at Urbino, is said to have been educated at Bologna, and was probably in the service of Guido Ubaldo, duke of Urbino, before 1498, as in the dedication of his first work, *Liber Proverbiorum* (April 1498), he styles himself this prince's client. Polydore's second book, *De Inventoribus Rerum*, is dedicated to Guido's tutor, Ludovicus Odaxius, from Urbino, in Aug. 1499. After being chamberlain to Alexander VI. he came to England in 1501 as deputy collector of Peter's pence for the cardinal. As Hadrian's proxy, he was enthroned bishop of Bath and Wells in Oct. 1504. It was at Henry VII.'s instance that he commenced his *Historia Anglica* (1534), on which he had been engaged for nearly 30 years. A rash letter, reflecting severely on Henry VIII. and Wolsey, was intercepted early in 1515, after which Polydore was cast into prison for several months, and supplanted in his collectorship (March and April). In 1525 he published the first edition of *Gildas*, dedicating the work to Tunstall, bishop of London. Next year appeared his *Liber de Prodigiis*, dedicated from London (July) to Francesco Maria, duke of Urbino. Somewhere about 1538 he left England, and remained in Italy for some time. About the end of 1551 he went home to Urbino, where he appears to have died in 1555. He had been naturalized an Englishman in Oct. 1510, and had held several clerical appointments in England. In 1508 he was appointed archdeacon of Wells, and in 1513 prebendary of Oxgate in St. Paul's cathedral, both of which offices he held after his return to Urbino.

The first edition of the *Historia Anglica* (26 books) was printed at Basle in 1534; the 27th book, dealing with the reign of Henry VIII. down to the birth of Edward VI. (October 1536), was added to the third edition of 1555. It is mainly from the time of Henry VI. that Polydore's work is useful.

Polydore's *Adagia* (Venice, April 1498) was the first collection of Latin proverbs ever printed; it preceded Erasmus's by two years, and the slight misunderstanding that arose for the moment out of rival claims gave place to a sincere friendship. A second series of Biblical proverbs (553 in number) was dedicated to Wolsey's follower, Richard Pace, and is preceded by an interesting letter (June 1519), which gives the names of many of Polydore's English friends, from More and Archbishop Warham to Linacre and Tunstall. The *De Inventoribus* treating of the origin of all things whether ecclesiastical or lay (Paris, 1499), originally consisted of only seven books, but was increased to eight in 1521. It was exceedingly popular, and was early translated into French (1521), German (1537), English (1546) and Spanish (1551). All editions, however, except those following the text sanctioned by Gregory XIII. in 1756, are on the Index Expurgatorius. The *De Prodigiis* also achieved a great popularity, and was soon translated into Italian (1543), English (1546) and Spanish (1550).

VIRGINAL or **PAIR OF VIRGINALS,** a name applied in England (and also recognized on the Continent of Europe) to the spinet as being pre-eminently an instrument for girls. (For further particulars *see* PIANOFORTE and SPINET.)

VIRGINIA or **VERGINIA,** in Roman legendary history, daughter of L. Virginius, a plebeian centurion. Her beauty attracted the notice of the decemvir Appius Claudius, who instructed Marcus Claudius, one of his clients, to claim her as his slave. Marcus accordingly brought her before Appius, and asserted that she was the daughter of one of his female slaves, who had been stolen and passed off by the wife of Virginius as her own child. Appius, refusing to listen to any argument, declared Virginia a slave and the property of Marcus. Virginius thereupon stabbed her to the heart in the presence of Appius and the people. A storm of popular indignation arose and the decemvirs were forced to resign. The people for the second time "seceded" to the Sacred Mount, and refused to return to Rome until the old form of government was re-established.

See Livy iii. 44–58; Dion. Halic. xi. 28–45, whose account differs in some respects from Livy's; Cicero, *De finibus*, ii. 20; Val. Max. vi. 1, 2; for a critical examination of the story and its connection with the downfall of the decemvirs, *see* Schwegler, *Röm. Gesch.*, bk. xxx. 4, 5; E. Pais, *Ancient Legends of Roman History* (Eng. trans. 1906), p. 185.

VIRGINIA, "The Old Dominion," is the most southerly of the middle Atlantic group of States in the United States of America, and lies between 36° 30′ and 39° 37′ N. lat., and 75° 15′ and 83° 40′ W. long. The Potomac river separates it on the north from Maryland, except east of Chesapeake bay where the boundary is a parallel of latitude. Another parallel of latitude separates it on the south from North Carolina and Tennessee. On the east lies the Atlantic ocean, along which the State possesses a tidal shore-line, following indentations, of 780 miles. The States of Kentucky and West Virginia form the western boundary. The total area is 42,627 sq.m., of which 2,365 sq.m. are water surface included in land-locked bays and harbours, rivers and lakes. In length east and west along the southern boundary the State measures about 440 m., its extreme breadth north and south is about 200 miles. The State is the remnant of a much greater area named by Sir Walter Raleigh "Virginia" in honour of Queen Elizabeth, who was known as "The Virgin Queen."

Physiography.—Virginia is crossed from north-east to south-west by three distinct physiographic provinces, which, named from east to west, are: (1) The Coastal plain or Tidewater region, including the Eastern Shore; (2) The Piedmont plateau; (3) the Appalachian Mountain province. The latter is sometimes subdivided (from east to west) into the Blue Ridge, Great valley and Alleghany ridges. The Tidewater province occupies about 11,000 square miles. Once the plain of which it is formed was raised to a higher elevation above sea level than now, and it was much dissected by streams. When it was subsequently depressed, the sea invaded these stream valleys to form the branching bays which characterize the region. Chief of these are the long estuaries of the lower Potomac, Rappahannock, York and James rivers. Chesapeake bay, into which these flow, is itself the drowned lower course of the Susquehanna. The land between these arms of the ocean is relatively flat. In the south-east, where

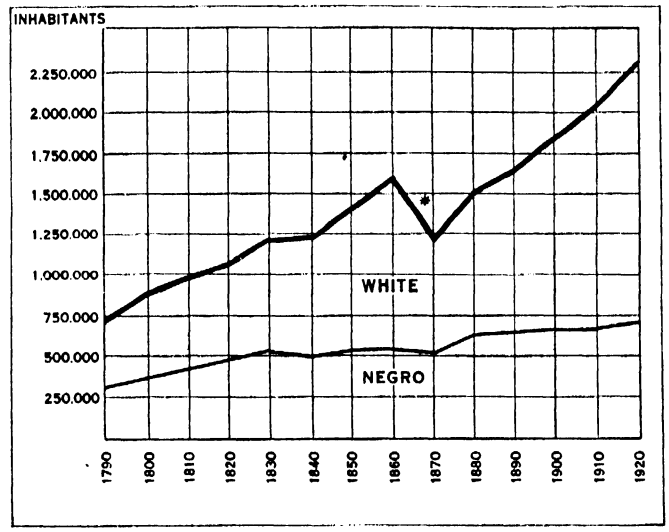
the drainage is particularly poor, is the Great Dismal Swamp (*q.v.*), a fresh-water marsh covering 700 square miles. Along the shores of Chesapeake bay and the Atlantic ocean are low, sandy beaches, often enclosing lagoons or salt marshes. Westward the Tidewater province reaches to the "fall-line" of the rivers, approximated by a line drawn north and south through Richmond.

The largest of the physiographic provinces, the Piedmont plateau, extends from an elevation of 150 to 300 ft. along the "fall-line" westward to an elevation of 700 to 1,200 ft. along the foot of the Blue Ridge. It varies in width from 40 m. in the north to about 175 m. along the southern border. The sloping surface is gently rolling, and has resulted from the uplift and dissection of a nearly level plain of erosion developed on folded crystalline rocks. Occasional hard rock ridges rise to a moderate elevation.

The mountain belt known as the Blue Ridge, from 3 to 20 m. in breadth, passes entirely across the State from north-east to south-west and forms the division between the Piedmont plateau and the Great valley. In elevation it varies from 1,460 ft. at Harper's Ferry, where the Potomac breaks through it in a picturesque water-gap, to 5,719 ft. in Mt. Rogers, Grayson county, the highest point in the State. In the north the range is narrow, but southward it broadens toward a greater expansion in west North Carolina and east Tennessee. Most of the rivers flowing through the Piedmont district to the Tidewater region have their origin on the eastern slopes of the Blue Ridge, but two of the largest, the James and Roanoke rivers, have cut passes through from the Great valley where they have their origin.

The Great valley is in its general configuration one continuous valley between the two great mountain ranges extending diagonally across the State, but it is drained by five separate rivers, each with its separate valley. The Shenandoah river drains the northern one-third and flows north into the Potomac at Harper's Ferry. The middle one-third is drained by the upper tributaries of the James and Roanoke rivers which break through the Blue Ridge and flow east. The southern one-third of the valley is drained by the New river, which breaks through the Allegheny ridges to the west and flows to the Ohio, and by the Holston river, which flows south-west into Tennessee. The valley averages from 25 to 30 m. in width and rises in elevation from 300 ft. at Harper's Ferry to about 1,700 ft. in south-west Virginia. Its formations are mostly of limestone, which accounts for the many remarkable caves in the region, and the famous Natural bridge, 215 ft. high, in Rockbridge county.

The altitude of the mountainous ridges to the west of the Great valley varies from 1,500 to above 4,000 feet. Some of the valleys and slopes are of sandstone, some of slates and shales, some of limestone, so that they present a great variety of surface.



The rainfall is everywhere sufficient for farming. Snowfall is confined almost entirely to the three winter months and in the Piedmont and Tidewater region snow is infrequent and of short duration. In the mountains it often becomes very deep.

Flora.—The Coastal plain is covered with pine forests, which merge westward with the hard woods of the Piedmond section, where oaks formerly prevailed, but where a second growth of pine now constitutes part of the forest. The Blue Ridge and Allegheny regions are covered with pine, hemlock, white oak, cherry and yellow poplar; while toward the south-west corner of the State there are still groves of walnut and hickory. The cypress grows in the Dismal swamp, the river birch along the streams of the coastal plain, and sweet gum and black gum where the ground is swampy. Characteristic plants of the coastal region are the cranberry, wild rice, wild yam, wax myrtle, wistaria, trumpet flower, passion flower, holly and white alder. Many of these continue into the Piedmont section. Rhododendron, mountain laurel and azaleas are common in the mountains.

Population.—In 1790, the year of the first Federal Census, Virginia ranked first among the States in population, with 747,610 inhabitants. By 1860, just before the Civil War, population had about doubled. The separation of West Virginia during the Civil War lowered the total to 1,255,163 in 1870, but in 1900 it was 1,893,810, in 1910, 2,061,612 and in 1920, 2,309,187. The population July 1, 1928 was estimated by the Federal Census Bureau at 2,575,000. The density increased from 46·1 per sq.m. in 1900 to 57·4 per sq.m. in 1920.

Of the total in 1920 1,617,909 were of the white race, 690,017 were negroes, 824 Indians and 437 of other races. The percentage of negroes had decreased from 35·6 in 1900 to 32·6 in 1910 and 29·9 in 1920. They were most numerous in the Tidewater region and in the south-eastern counties of the Piedmont district.

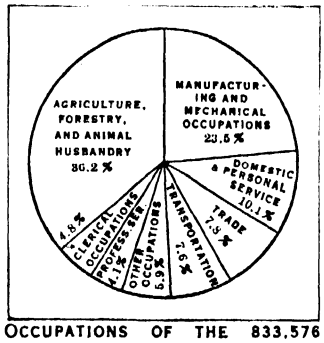
Of the white population 1,534,494, or 94·8%, were natives—born of native parentage. Those born of foreign or mixed parentage numbered 52,630 and those who were born in foreign lands numbered 30,785. The percentage of illiteracy among the population over 10 years of age amounted for the State as a whole to 11·2; among the native whites it was 5·9%; among the negroes 23·5%. The proportion of the population living in cities of more than 2,500 inhabitants increased from 18·3 in 1900 to 23·1 in 1910 and 29·2 in 1920. The chief cities with their population according to the 1910 and 1920 censuses, together with the estimate of the Census Bureau for July 1, 1928, follow:

GRAPH SHOWING THE GROWTH OF POPULATION IN VIRGINIA, AND THE NEGRO ELEMENT PERCENTAGE

City	1910	1920	Estimate 1928
Richmond	127,628	171,667	194,400
Norfolk	67,452	115,777	184,200
Roanoke	34,874	50,842	64,600
Portsmouth	33,190	54,387	61,600
Newport News	22,622	35,596	53,300
Lynchburg	29,494	30,070	38,600
Petersburg	24,127	31,012	37,800

Government.—Virginia has had six State Constitutions: the first was adopted in 1776, the second in 1830, the third in 1851, the fourth in 1864, the fifth in 1869 and the sixth, the present, in 1902. Amendments to the present Constitution may be proposed in either house of the general assembly, and if they pass both houses of that and the succeeding general assembly by a majority of the members elected to each house and are subsequently approved by a majority of the votes polled at the next general election they become a part of the Constitution. A majority of the members in each house of the general assembly may at any time propose a convention to revise the Constitution and, if at the next succeeding election a majority of the voters approve, the general assembly must provide for the election of delegates. To be entitled to vote one must be a citizen of the United States and 21 years of age; have been a resident of the State for one year, of the county, city or town for six months, and of the election precinct for 30 days next preceding the election.

The general assembly consists of a senate and a house of delegates. Senators and delegates are elected by single districts (into which the State is supposed to be apportioned once every ten years according to population), the senators for a term of



four years, the delegates for a term of two years. The membership of both the senate and the house was in 1927 at the maximum allowed by the State Constitution, 40 senators and 100 delegates. The general assembly meets regularly at Richmond on the second Wednesday in January of each even-numbered year. The length of a regular session is limited to 60 days unless three-fifths of the members of each house concur in extending it.

The governor, lieutenant-governor and attorney-general are elected for a term of four years. The governor appoints the secretary of the commonwealth, treasurer, superintendent of public buildings, commissioner of agriculture, controller and numerous officers with the concurrence of the general assembly. He has the power of vetoing legislative bills or any item of an appropriation bill (a bill can be passed over his veto by a two-thirds vote of the members present in each house), and has authority to inspect the records of officers or to employ accountants to do so, and to suspend, during a recess of the general assembly, any executive officer at the seat of government except the lieutenant-governor.

A consolidation and reorganization of administrative bodies was effected by a legislative act in 1927 which created 12 administrative departments, namely, the departments of taxation, finance, highways, education, corporations, labour and industry, agriculture and immigration, conservation and development, health, public welfare, law, and workmen's compensation.

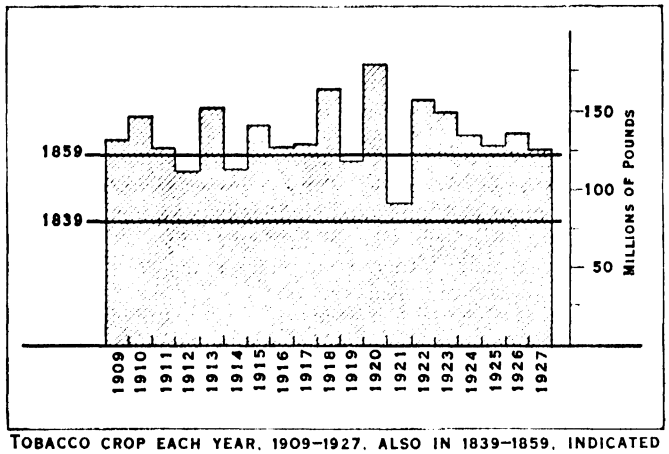
The administration of justice is vested in a supreme court of appeals, circuit courts, city courts and justices of the peace. The supreme court of appeals consists of seven judges, but any three of them may hold a court or they may sit in two divisions of not less than three judges each except in cases involving constitutional questions, when the full court is required. They are chosen for a term of 12 years by the joint vote of the two houses of the general assembly. The court sits at Richmond, Staunton and Wytheville. Provision is made for a special court of appeals where the majority of the judges of the supreme court may not properly sit or where the docket of that court is too crowded to be disposed of "with convenient dispatch." The State is divided into 34 judicial circuits and in each of these a circuit judge is chosen for the term of eight years by a joint vote of both houses of the general assembly. Similar to the circuit court is the corporation court in each city having a population of more than 10,000, the judge of which is also chosen by a joint vote of both houses for a term of eight years.

Finance.—The value of all tangible property in the State has increased from $1,288,000,000 ($666 per caput) in 1904 to $2,402,000,000 ($1,140 per caput) in 1912 and $4,892,000,000 ($2,050 per caput) in 1922 as estimated by the Federal Census Bureau. The valuation of property assessed for taxation purposes in 1925 amounted to $2,119,643,765, of which $1,048,188,000 was real estate. In 1926 the rates of taxation per $100 assessed valuation were 25 cents for real estate and tangible personal property, and 50 cents on intangible property, except capital, which was $1.00, bonds of counties, cities and towns which were 35 cents and shares of bank stock which were 25 cents.

OCCUPATIONS OF THE 833,576 PERSONS TEN YEARS OF AGE AND OVER ENGAGED IN GAINFUL EMPLOYMENT, 1920

Receipts and disbursements of the State treasury during the fiscal year ending June 30, 1926, amounted to $32,721,421 and $32,371,260 respectively. The chief items of expenditure were for the construction and maintenance of roads, $14,167,526; for the support of free public schools, $5,142,770; for educational and charitable institutions, $2,272,162; for expenses and salaries of officers of the Government, $1,088,367; for hospitals for the insane and for epileptics, $1,082,843, and for pensions to soldiers, sailors, marines and their widows, $947,507. The total outstanding State debt amounted in 1925 to $26,870,000, or $11.03 per caput. Of this aggregate debt $19,539,000 was funded.

Education.—The Virginia free school system, established in 1870, is controlled by the State board of education, composed of seven members appointed by the governor. The chief executive of the system is the superintendent of public instruction also appointed by the governor. The Constitution provides that white and coloured children shall be taught in different schools. Attendance is compulsory for children from 8 to 14 years of age, except for pupils of high school grade. The school census of 1925 recorded 701,534 children in the State from 7 to 19 years of age, of whom 216,802 were coloured. Of the total 551,475 were enrolled in public schools during the 1925–26 session. In addition there were approximately 35,000 in private and parochial schools of which Virginia has a large number. The average length of school term was 161 days. There were 12,770 school rooms devoted to white children and 3,602 for coloured children. Accredited four year high schools numbered 369 and accredited junior high schools 12. There were 58,676 pupils enrolled in high schools and 2,459 high school teachers.



Between 1915 and 1926 one-roomed schools had decreased in number from 4,666 to 3,460, two-roomed schools had increased from 1,082 to 1,529 and schools over two rooms had increased from 988 to 1,317. The value of school sites and buildings had increased from $15,206,000 to $45,893,000. School expenditures for 1925–26 amounted to $23,788,215 of which $4,108,176 was for further capitalization leaving $19,680,039 for operation, maintenance and instruction. Annual expenditures per child 5 to 17 yrs. of age inclusive averaged $28.85 in 1925.

Institutions for higher learning receiving State support are the University of Virginia at Charlottesville, the College of William and Mary at Williamsburg, the Virginia Polytechnic institute at Blacksburg, the Medical college of Virginia at Richmond, the Virginia Military institute at Lexington, four State teacher's colleges for women, located at Farmville, Fredericksburg, Harrisonburg and Radford. These are for whites. The State supports one normal school for coloured teachers at Petersburg, and in addition there is the Hampton Normal and Industrial institute at Hampton, supported by endowment. Special schools are the Virginia School for the Deaf and Blind at Staunton, and the Virginia School for the Coloured Deaf and Blind at Newport News. Important private institutions of higher learning are: for men, Washington and Lee university at Lexington, Roanoke college at Salem. University of Richmond, which includes Westhampton college (for women), Emory and Henry college at Emory, Hampden-Sidney college at Hampden-Sidney, Bridgewater college at Bridgewater, Randolph-Macon college at Ashland and Lynchburg college; for women, Hollins college at Hollins, Randolph-Macon Woman's college at Lynchburg, and Sweet Briar college at Sweet Briar. Virginia Union university at Richmond is for coloured students. For theological education there are the Theological seminary at Alexandria (Episcopal) and the Union Theological seminary at Richmond (Presbyterian).

Charities and Corrections.—The department of public welfare has for its duties the inspection of all State, county, municipal and private institutions of a charitable or correctional nature, or those which have to do with the care or training of defective, dependent, neglected or criminal classes. It also enforces the juvenile and probations laws, inspects maternity hospitals, child-placing agencies, children's nurseries and orphan homes and administers mother's aid to widows with children under 16 years of age. The State penitentiary is located at Richmond, and there is a State penitentiary farm at Lassiter. There is a State home and industrial school for white girls at Bon Air and for coloured girls at Peaks Turnout, a State industrial school for white boys at Beaumont and for coloured boys at Hanover.

Agriculture and Live Stock.—Agriculture is an important industry of Virginia. Its fluctuating fortunes are revealed by the following figures. The value of all farm property amounted in 1910 to $625,065,000, in 1920 to $1,196,556,000 and in 1925 to $999,466,000. The amount of land in farms decreased from 19,908,000 ac. in 1900 to 18,561,000 ac. in 1920 and 17,210,000 ac. in 1925 or from slightly more than three-fourths the area of the

State in 1900 to approximately two-thirds the area in 1925. Despite this loss in acreage the number of farms increased from 186,242 in 1920 to 193,723 in 1925, their average size decreasing from 99·7 ac. in 1920 to 88·8 ac. in 1925. The average value per acre of farm land decreased in the same five years from $40.75 to $34.90. Farm population was 1,064,417 (46·1% of the total) in 1920 and 980,162 (39·4% of the total) in 1925. Of the 193,723

TOBACCO CROP EACH YEAR, 1909–1927. ALSO IN 1839–1859, INDICATED BY THE HORIZONTAL LINES CROSSING THE FIGURE

farms in 1925, 143,587 were operated by their owners, 48,898 by tenants and 1,238 by managers. White farmers numbered 143,576 and coloured farmers 50,147.

The yield of all crops was better than average in 1926 and the production of all crops, with the exception of peanuts and potatoes, was greater than in 1925. The total value of all crops in 1926 was estimated to be $178,348,000 ($112,703,000 in money crops sold direct, $65,645,000 in crops fed to live stock), compared with $164,784,000 in 1925. Virginia in 1926 ranked first among States in the production of early potatoes, spinach and in shipments of sweet potatoes; second in the production of peanuts; third in the production of tobacco and commercial apples; and fifth in the total value of truck crops. The 1926 acreage of leading crops was as follows: corn, 1,694,000; hay, 979,000; wheat, 687,000; tobacco, 188,000; oats, 186,000; peanuts, 138,000; white potatoes, 134,000; cotton, 101,000; sweet potatoes, 43,000; rye, 43,000. The leading crops in order of value were as follows: corn, $39,597,000; tobacco, $25,412,000; tame hay, $19,344,000; white potatoes, $18,070,000; wheat, $14,850,000; apples, $10,450,000; sweet potatoes, $5,375,000; peanuts, $5,244,000; cotton, $3,135,000; oats, $3,047,000; peaches, $1,176,000; sorghum (for syrup), $1,140,000. Of minor value were rye, soy beans, barley, buckwheat, pears and cow peas. The great acreage of tobacco, potatoes and truck crops gives Virginia a high rank in the average value per acre of all crops. Tobacco is the most important strictly money crop. With few exceptions its cultivation is confined to the section east of the Blue Ridge and west of the fall-line, and, excepting portions of a half-dozen counties, south of the James river. The Great valley and the Alleghany valleys are unsurpassed hay regions. Clover, timothy, herdsgrass or redtop, and alfalfa grow anywhere in the State. Long seasons and abundant rainfall give several cuttings. Wheat is the principal money crop in the Shenandoah and Rappahannock river valleys. Cotton and peanuts are grown almost entirely in the south-eastern counties, where they constitute a large share of the farm income. During 1926 141,410 ac. were devoted to truck crops valued at $19,215,000, the chief items, besides potatoes, being strawberries ($2,904,000), spinach, cabbage, beans, tomatoes and cucumbers.

The number and value of live stock on farms Jan. 1, 1927, were as follows: horses, 224,000, $14,784,000; mules, 103,000, $8,755,000; milch cows, 340,000, $15,300,000; other cattle, 367,000, $10,680,000; sheep, 380,000, $3,914,000; swine, 558,000, $7,254,000; chickens, 9,972,000, $9,174,000. The estimated value of dairy products in 1926 was $14,918,000, of poultry products $28,137,000, of live stock sold or slaughtered $31,345,000, of honey, $650,000 and of wool $664,000.

Fisheries.—Virginia has about 3,000 sq.m. of tidal waters along the eastern coast and in Chesapeake bay where commercial fishing proves very profitable. In 1920 the season's catch totalled 471,219,089 lb. valued at $8,541,724. In 1925 it amounted to 276,227,784 lb. valued at $9,084,641. In value the 1925 catch exceeded that of all other Atlantic and Gulf States, except Massachusetts. The season is usually about 5½ months in the spring and summer, and employs about 30,000 men. Chesapeake bay produces more oysters than any other body of water in the world, and Maryland and Virginia lead all States in oyster production with over 5,000,000 bu. annually. There were in Virginia in 1925 56,744 ac. of recorded oyster-planting grounds, the chief locations beside Chesapeake bay being Chincoteague bay, the western shore of Accomac and Northampton counties, and the Potomac, Rappahannock, York and James rivers.

Mines and Quarries.—Virginia's mineral resources are abundant and varied. Many are as yet undeveloped. In 1926 there were 142 mines and quarries which employed 18,223 workers. Capital invested totalled $51,949,594. The value of output amounted to $33,522,630, compared with $41,038,000 in 1925 and $29,363,000 in 1919. Chief in point of value was coal, in the mining of which in 1926 15,413 men (exclusive of office help) were engaged. There were 88 mines operating an average of 234 days each during the year. Their output was 13,949,224 short tons valued at $27,098,734. Coal is found in Virginia in three important districts. The Pennsylvania coal measures extend into the seven Alleghany counties in the extreme south-western corner, and it is from here that the bulk of the output comes. In Tazewell county is the famous Pocahontas bed which produces one of the highest grades of coking and steam coal to be found in the United States. There is a coal field of Mississippian age in the counties of the Great valley bordering the New river, in which production is still light, but rapidly increasing. Just a short distance west of Richmond is a third bed, one of the first in the United States to be mined, and still a steady producer. There are rich deposits of iron ore in the Alleghanies and western slopes of the Blue Ridge and iron mining has been carried on since the 17th century. Rocks quarried for various uses included granite, limestone, marble, sandstone, slate and basalt, and of all there are practically unlimited quantities.

Manufactures.—In this branch of industry there has been rapid growth. In 1914 there were 5,508 establishments employing 102,820 wage-earners and having an output valued at $264,039,000. In 1927 there were 3,680 establishments employing 132,647 wage-earners, and turning out products valued at $782,425,841. Wages paid increased from $44,873,000 in 1914 to $126,440,387 in 1927. Compared with 1926 there were in 1927 1,112 more establishments, 34,723 more wage-earners, $26,007,512 more paid in wages, $265,165,710 more invested in capital, and $114,575,404 additional value of output. The total capital invested in manufactures was estimated at $733,482,337. Of the wage-earners 124,050 were male and 39,010 were female; 112,845 were white and 50,215 were coloured.

The chief manufactures were those connected with tobacco. The State in 1927 ranked fourth in the manufacture of cigars and cigarettes, and third in the production of chewing and smoking tobacco and snuff. In that year the value of tobacco products reached $182,071,911, an increase over 1926 of $37,461,987. Second in importance were the textile industries, cotton mill products being valued at $30,380,994, silk mill products at $29,640,382 and woollen mill products at $3,193,104. Lumber and wood products are probably third in importance as a class. The output of sawmills in the State was valued at $10,569,083, of sash and door factories at $17,991,711, of furniture factories at $23,199,968, of box and crate factories at $14,088,611, of cooperage, barrels and staves, at $2,756,152. An output valued at $32,071,124 gives iron and machinery manufactures fourth place in importance. Other products ranking high among the manufactures of the State were those of abattoirs and meat packing establishments. $16,687,275; automobile accessories, $24,668,520; paper and pulp mill products, $27,571,434; shipbuilding, $31,745,895; and flour

and grist mill products, $20,419,833.

The chief manufacturing city in 1927 was Richmond with 621 establishments, 31,881 wage-earners, and products valued at $290,052,593. Tobacco products predominate and Richmond in 1927 had the largest cigar factory in the world. It was the location also of large locomotive and wood work plants. Far behind in the value of their products were Norfolk, $35,454,000; Roanoke, $32,013,000; Lynchburg, $25,579,000; Newport News, $19,719,000; Petersburg, $17,342,476; Danville, $12,303,000, and Portsmouth, $11,230,000. At Hopewell the first unit of the $125,000,000 Atmospheric Nitrogen Plant is (1928) in production.

Virginia has the advantages of excellent transportation, high-grade steam coal and abundant water-power resources. Where the Tidewater region joins the Piedmont section there is an abrupt rocky ledge that forms falls and rapids in the rivers that pour over it. At this fall-line with its excellent power sites are the cities of Petersburg, Richmond and Fredericksburg, while Alexandria is located near the falls of the Potomac.

Transportation and Commerce.—Five large railway systems practically originate in the State and radiate to the south and west. The Southern railway, with its main line traversing the State in the direction of its greatest length leaves Washington to run south-west through Charlottesville, Lynchburg and Danville to the North Carolina line with connections to Richmond and Norfolk on the east; the Atlantic Coast line with its main lines runs south from Richmond and Norfolk; the Seaboard Air line also has its main lines running to the south from Richmond and Norfolk; the Norfolk and Western crosses the State from east to west in the southern part with Norfolk its eastern terminus and the Chesapeake & Ohio crosses from east to west farther north from Newport News on the eastern coast through Richmond to the West Virginia line. Of more recent construction is the Virginia railway, opened for traffic in 1909, which connects the coal region of West Virginia with Norfolk. The Baltimore & Ohio has a line down the Shenandoah valley to Lexington. Connection between Richmond and Washington is over the Richmond, Fredericksburg and Potomac, controlled by the Southern, Atlantic Coast line, Seaboard Air line, Chesapeake & Ohio, Pennsylvania and Baltimore and Ohio railways.

Hampton Roads, at the mouth of the James river, which forms the harbour for the leading ports of the State, Norfolk and Newport News, affords one of the best anchorages of the Atlantic coast, giving shelter not only to vessels plying to its adjoining ports but serving often as a harbour of refuge for shipping bound up or down the coast. It is frequently used for the assembly of naval fleets. There is a large foreign commerce and regular steamship service to Boston, Providence, New York, Philadelphia and Savannah. There is bay and river steamship service from Norfolk, Old Point Comfort and Newport News to Baltimore, Washington, Fredericksburg, Richmond and Petersburg.

There were in 1926 59,080 m. of public highways in Virginia, 5,210 of which constitute the State highway system and 12,000 a State aided system. Of the State system 3,839 m. were surfaced. Expenditures by the State highway department in 1925 were $14,072,000, and by local political divisions for rural roads $22,576,000. Motor vehicles numbered 322,614 in 1926, averaging 128 per 1,000 population.

HISTORY

Virginia was the first permanent English settlement in North America. From 1583 to 1588 attempts had been made by Sir Walter Raleigh and others to establish colonies on the coast of what is now North Carolina. The only result was the naming of the country Virginia in honour of Queen Elizabeth. But glowing accounts were brought back by the early adventurers, and in 1606 an expedition was sent out by the London Company, which was chartered with rights of trade and settlement between 34° and 41° N. lat. It landed at Jamestown on May 13, 1607, and effected the establishment of many plantations along the James river. The purpose of the company was to build up a profitable commercial and agricultural community, and also to hold the country against Spain; but the hostility of the natives, unfavourable climatic conditions and the inexperience of the colonists delayed the growth of the new community. John Smith became the head of the government in Sept. 1608, governed with firmness and ability, built a church and prepared for more extensive agricultural and fishing operations. In 1609 the London Company was reorganized, other colonists were sent out and the boundaries of the new country were fixed, according to which Virginia was to extend from a point 200 m. south of Old Point Comfort, at the mouth of Chesapeake bay, to another point 200 m. north, "west and northwest to the South Sea."

Before the arrival of the new governing body and additional settlers the original Colony was reduced to the direst straits. Capt. Christopher Newport, Sir Thomas Gates and Sir George Somers, the new authorities, reached Jamestown at last with 150 men, but things were in such a deplorable state that all agreed (June 10, 1610) to give up the effort to found a colony on the James and set sail for home. At the mouth of the river they met Lord Delaware, the governor-in-chief, who brought other colonists and plentiful supplies; and they returned, set up a trading post at what is now Hampton and undertook to bring the hostile natives to subjection. In 1611, 650 additional colonists landed, the James and Appomattox rivers were further explored and "plantations" were established at Henrico and Bermuda Hundred. New colonists were constantly being sent over and many "indentured" servants were imported as labourers.

Struggles for Self-government.—At the beginning Virginia colonists had held their land and improvements in common. But in 1616 the land was parcelled out and the settlers were scattered along the banks of the James and Appomattox rivers many miles inland. The rapid expansion of tobacco culture soon made the community self-supporting. The year 1619 that saw the first negroes brought in also saw the first representative assembly in North America, the Virginia House of Burgesses, a meeting of planters sent from the plantations to assist the governor and council in reforming and remaking the laws of the Colony. In 1621, a Constitution was granted whereby the London Company appointed the governor and a council, and the people were to choose annually from their counties, towns, hundreds and plantations delegates to the House of Burgesses. The popular branch, like the English House of Commons, granted supplies and originated laws, and the governor and council enjoyed the right of revision and veto as did the king and the House of Lords at home. Later the council also originated bills. The council sat also as a supreme court to review the county courts and had in important cases original jurisdiction. This system remained unchanged throughout the colonial period but in 1624 the king took the place and exercised the authority of the London Company.

On March 22, 1622, the Indians fell upon the whites and slew 350 persons. Sickness and famine once again visited the Colony, and the population was reduced by nearly one-half. These losses were repaired, however; the tobacco industry grew in importance and the settlers built their cabins far in the interior of lowland Virginia. This rapid growth was scarcely retarded by a second Indian attack, in April 1644, which resulted in the death of several hundred settlers. By 1648 the population was 15,000.

In her attitude toward the war in England between King Charles and parliament, Virginia sympathized with the king. However, though Sir William Berkeley, who had been governor since 1641, was absolutely loyal to the crown, it was considered the part of wisdom to surrender to a fleet sent over by parliament in 1652, after a slight show of resistance; but substantial acknowledgments were made by the parliamentary commissioners of Virginia's rights. Richard Bennett, a Puritan, now ruled the province. He and his Puritan successors, Edward Digges and Samuel Mathews, made no serious change in the administration of the Colony. The return of Berkeley, who was restored to power in 1660, was the beginning of a reaction which concentrated authority in the hands of the older families and thus created a privileged class. The governor, supported by the privileged families, retained the same House of Burgesses for 16 years lest a new one might not be submissive. The increasing mass of the population who dwelt along the western border and on the less fertile ridges developed

a feeling of hostility towards the oligarchy. They desired a freer land-grant system, protection against the inroads of the Indians along the border and frequent sessions of an assembly to be chosen by all the free-holders. In 1676 the Indians again attacked the border farmers, but the governor had refused assistance, being willing, it was charged, that the border population should suffer while he and his adherents enjoyed a lucrative fur trade with the Indians. Under these circumstances Nathaniel Bacon (1647–76), took up the cause of the borderers and severely punished the Indians at the battle of Bloody Run. Berkeley meanwhile had outlawed Bacon, whose forces now marched on the capital demanding recognition as the authorized army of defence. This was refused and civil war began, in which the governor was defeated and Jamestown was burned. But Bacon fell a victim to malaria and died in October in Gloucester county. Berkeley closed the conflict with wholesale executions and confiscations. Censured by the king, he sailed to England to make his defence, but died in London in 1677 without having seen Charles. Until the accession of William and Mary there was continued unrest in Virginia and a bitter struggle between the popular party in Virginia and the English Government seeking to reduce the privileges of the House of Burgesses. In many respects the Government came off victorious but the House retained the all important power of levying taxes. In 1689 James Blair was made commissary in Virginia of the Bishop of London and throughout a long life did valiant service for the Colony. In 1692 he obtained the charter for William and Mary college and became its first president. It was founded at Williamsburg, which in 1699 was made the capital.

Westward Expansion.—By 1700 the population of Virginia had reached 70,000, of whom 20,000 were negro slaves. The majority of whites were small farmers, who constantly encroached upon the Indian lands in the Rappahannock region or penetrated the forests south of the James, several thousand having reached North Carolina. Between 1707 and 1740 many Scottish immigrants (traders, teachers and tobacco-growers) settled along the upper Rappahannock, and, uniting with the borderers in general, they offered strong resistance to the older planters.

Tobacco-growing was the one vocation of Virginia, and many of the planters were able to spend their winters in London or Glasgow and to arrange for their sons to attend the finishing schools of the mother country. Negro slavery grew so rapidly during the first half of the 18th century that the blacks outnumbered the whites in 1740. In 1716 an expedition of Governor Alexander Spotswood over the mountains made known to the world the rich back-country, now known as the Valley of Virginia. A migration thither from Pennsylvania and from Europe followed in course of time which revolutionized the province. The majority of blacks over whites soon gave way before the influx of white immigrants, and in 1756 there was a population of 292,000, of whom only 120,000 were negroes, and the small farmer class had grown so rapidly that the old tidewater aristocracy was in danger of being overwhelmed. The "West" had now appeared in American history. This first West, made up of the older small farmers, of the Scottish settlers, of the Germans from the Palatinate and the Scottish-Irish, far outnumbering the people of the old counties, demanded the creation of new counties and proportionate representation in the Burgesses. They did not at first succeed, but when the Seven Years' War came on they proved their worth by fighting the battles of the community against the Indians and the French. When the war was over the prestige of the up-country had been greatly enhanced, and its people soon found eastern leaders in the persons of Richard Henry Lee and Patrick Henry. In the meantime the Presbyterians, who had been officially recognized in Virginia under the Toleration Act in 1699, and had been guaranteed religious autonomy in the Valley by Governor Gooch in 1738, had sent missionaries into the border counties of eastern Virginia. The Baptists somewhat later entered the Colony both from the north and the south and established scores of churches. The new denominations vigorously attacked the methods and immunities of the established church, whose clergy had grown somewhat lukewarm in zeal and a few of them lax in morals. When the clergy, refusing to acknowledge the authority of the burgesses in reducing their stipends, and, appealing to the king against the assembly, entered the courts to recover damages from the vestries, Patrick Henry at Hanover court in 1763 easily convinced the jury and the people that the old church was well-nigh worthless. From this time the old order was doomed. The passage of the Stamp Act hastened the catastrophe and gave the leaders of the new combination, notably Henry, an opportunity to humiliate the British ministry, whom not even the tidewater party could defend. The Townshend scheme of indirect taxation displeased Virginia quite as much as had the former more direct system of taxation. When the burgesses undertook in May 1769 to discuss the right and power of taxation, the governor hastily dissolved them only to find the same men assembling in the Raleigh tavern in Williamsburg and issuing resolutions in defiance of executive authority.

The Struggle for Independence.—The struggle with England reached a crisis. Virginia, supporting with zeal the revolutionary movement, took the lead in the Continental Congresses which directed the succeeding war (*see* UNITED STATES: *History*). In April 1775, Patrick Henry at the head of the Hanover minute men, who had been joined by others, compelled Governor Dunmore (*q.v.*) to pay for the Colony's powder removed by the governor's order to a British war vessel. On June 8, Lord Dunmore and his family took refuge aboard an English man-of-war lying off Yorktown. When the Continental Congress issued the famous Declaration of Independence, Virginia had already assembled in convention to draft a new Constitution. A draft of a Constitution containing universal suffrage, proportional representation and religious freedom was sent to the convention by Jefferson, but the convention rejected it. The system which was adopted allowed the older counties a large majority of the representatives in the new assembly, on the theory that the preponderance of property (slavery) in that section required this as security against the rising democracy. The franchise, though not universal, was generously bestowed; it was a very liberal freehold system.

Of actual fighting there was not a great deal in Virginia till the later years of the war, for Lord Dunmore was soon driven out of the State, not, however, before he had done much damage along the seaboard and the largest town in the State, Norfolk, had been burned. The British came again in May 1779, took Portsmouth and Suffolk, burning the latter and plundering the surrounding country. In Jan. 1781, Benedict Arnold captured Richmond, now the capital. His force was not large but it was composed of regulars, and Jefferson, who was then governor, found it impossible to collect a sufficient force in time to offer effective resistance. Later in the year, Cornwallis came up with his troops from the south and made a junction with the British already in Virginia. A masterly campaign by the Americans, supported by a French army and fleet, resulted in the surrender of Cornwallis and his forces at Yorktown on Oct. 19, 1781. This was the closing scene of the struggle of American independence. In the meantime George Rogers Clark, in command of Virginians, had conquered that vast domain known later as the North-west Territory.

Virginia and the Federal Constitution.—Virginia leaders, including Henry, were the first to urge the formation of a national government with adequate powers to supersede the lame confederacy. In 1787, under the presidency of Washington, the National Convention sat in Philadelphia, with the result that the present Federal Constitution was submitted to the States for ratification during 1787–89. In Virginia the tidewater leaders urged adoption, while the up-country men, following Henry, who thought that the Federal Government was given too much power, opposed; but after a long and bitter struggle, in the summer of 1788 the new instrument was accepted, the low-country winning by a majority of ten votes, partly through the influence of James Madison.

In 1784, Virginia ceded to the Federal Government the North-west Territory, which it held under the charter of 1609 and also by conquest; in 1792 another large strip of the territory of Virginia became an independent State under the name of Kentucky. But the people of these cessions, especially of Kentucky, were closely allied to the great up-country party of Virginia, and altogether they formed the basis of the Jeffersonian democracy, which from 1794 opposed the chief measures of Washington's

administration, and which on the passage of the alien and sedition laws in 1798 precipitated the first great constitutional crisis in Federal politics by the adoption in the Kentucky and Virginia legislatures of resolutions strongly asserting the right and duty of the States to arrest the course of the National Government whenever in their opinions that course had become unconstitutional. The election of 1800 rendered unnecessary all further agitation by putting Jefferson in the president's chair. The up-country party in Virginia, with their allies along the frontiers of the other States, was now in power, and the progressives of 1776 shaped the policy of the nation during the next 25 years. Virginia held the position of leadership in Congress, and controlled the cabinet. Virginia also gave to the Supreme Court its greatest chief justice, John Marshall.

A Constitutional Convention was called in 1829 to revise the fundamental law in such a way as to give the more populous counties of the west their legitimate weight in the legislature. The result was failure, for the democracy of small farmers which the east feared would have taxed slavery out of existence was denied proportionate representation. The slave insurrection under Nat Turner in 1831 led to a second abortive effort, this time by the legislature, to do away with the fateful institution. The failure of these popular movements led to a sharp reaction in Virginia, as in the whole South, in favour of slavery.

Secession and Reconstruction.—In the national elections of 1860 Virginia returned a majority of unionist electors as against the Democratic candidates, Breckinridge and Lane. The governor of Virginia called an extra session of the legislature soon after the Federal election, and this in turn called a convention to meet on Feb. 13, 1861. The majority of this body consisted of Unionists, but the convention passed the ordinance of secession when the Federal Government (April 17) called upon the State to supply its quota of armed men to suppress "insurrection" in the lower Southern States. An alliance was made with the provisional government of the Confederate States on April 25, without waiting for the vote of the people on the ordinance. The Convention called out 10,000 troops and appointed Col. Robert E. Lee of the United States army as commander-in-chief. On May 23, the people of the eastern counties almost unanimously voted approval of the acts of the convention, and some of the people of the north-western counties took steps to form the State of West Virginia. Richmond soon became the capital of the Confederacy.

BY COURTESY OF ERNEST CRANDELL, WASHINGTON, D.C.

HARPER'S FERRY, A HISTORIC TOWN IN VIRGINIA, SCENE OF THE FAMOUS ATTACK OF JOHN BROWN, AMERICAN ABOLITIONIST, IN 1859

The Civil War had already begun, and Virginia was of necessity the battle-ground. Of the six great impacts made upon the Confederacy, four were upon Virginia soil: the first Manassas campaign (1861), the Peninsula battles and battles around Richmond (1862), second Manassas (1862), Fredericksburg and Chancellorsville (1862–63) and the great Wilderness-Petersburg series of attacks (1864–65).

With the surrender of the Confederate army under Gen. Lee to Grant at Appomattox the task of reconstruction began. Governor Francis H. Pierpoint set up in Richmond a government based upon the Lincoln plan and supported by President Johnson, who, however, was in conflict with the majority in Congress, which passed over his veto a radical Reconstruction Act. According to the new policy Virginia, on March 2, 1867, became military district No. 1. Gen. John M. Schofield was put in charge, and under his authority a Constitutional Convention was summoned which bestowed the suffrage upon the former slaves. These, led by a small group of whites, that had come into the State with the invading armies, ratified the 14th and 15th amendments to the Federal Constitution and governed the community until 1869. Then the secessionists and Union men of 1861 united and regained control. Virginia was readmitted to the Union on Jan. 26, 1870.

The 20 years following the end of the war in 1865 were years of humiliation, poverty and political strife; also years of economic readjustment. In many cases farms were deserted by their owners, who moved to the cities or left the State entirely. The general poverty was augmented by a State debt of over $45,000,000 that had been contracted before the Civil War for works of internal improvement. By a bill passed in 1871 two-thirds of the debt was funded into bonds, and the remaining one-third was allotted to West Virginia as her fair share, though that State refused to admit the obligation. For two decades the debt settlement was the chief issue in Virginia politics and the main subject of legislative deliberation. Educational and other improvements, badly needed, were allowed to drift in the meantime. Final settlement was not arrived at until 1891–92. A bill establishing a State-wide system of public free schools was passed in 1870. Some educational progress had been made when the payment of the public debt began to absorb the school revenue. From 1870 to 1879 $1,544,765 was diverted from school funds for this purpose. In the latter year enrolment in the schools dropped from 202,244 to 108,074 and in some counties every school was closed. After 1882 the State began to repay this money, and schools reopened, but their work was still handicapped by irregular attendance and lack of good teachers.

Recovery and Progress.—One of the most encouraging economic developments after the Civil War was the gradual extension of railways. These in their turn served in time to aid in the development of other industries. By 1885 the railways had extended down the Eastern Shore, down the peninsula, into the Great valley and across the Piedmont region between Lynchburg and Danville. This railway development accelerated the growth of many villages and brought others into existence. Newport News came into existence as a shipping point during the decade 1880–90. The mineral wealth of the south-west began again to be developed on a large scale and agriculture to be intensively practiced. The recovery increased in momentum as the 20th century ushered in a more prosperous era. The new constitution of 1902 largely eliminated the negro from politics by laying down literacy and property qualifications for voting. With this issue gone the Republicans were free to take up the regular *rôle* of an opposition party and as such gradually gained strength, especially in the mining regions of the south-west. The Democrats retained control, however, from 1870 until the election of 1928 when events combined to throw the State's presidential vote into the Republican column.

VIRGINIA, a city of St. Louis county, Minnesota, U.S.A., 60 m. N.W. of Duluth, at an altitude of 1,500 ft., in the heart of the Mesaba iron range and the vast playground of "the Arrowhead country." It is served by the Duluth and Iron Range, the Duluth, Missabe and Northern, the Duluth, Winnipeg and Pacific, and the Great Northern railways. Pop. (1920) was 14,022 (34% foreign-born white); 1928 local estimate, 17,400. Mining and lumbering are the principal industries. Within the city limits are three sawmills, one of which (the largest in the world handling white pine) employs 3,500 to 4,000 men, and ships annually 200,000,000 ft. of lumber. The six iron mines of the immediate vicinity (worked by the stripping or open-pit method) employ 1,500 men and ship annually 5,000,000 tons of ore. The city owns and operates the water, gas, electric light and power plants, and also a steam plant which heats 94 blocks, serving 1,400 customers. Virginia was founded in 1892 and incorporated in 1905.

VIRGINIA, UNIVERSITY OF, a State institution for higher education, situated at Charlottesville, Va., among the foot-hills of the Blue Ridge Mountains. Its buildings, arranged around a large rectangular lawn, were erected from a plan prepared by Thomas Jefferson. The university comprises 26 independent schools, but the courses of instruction given in these are so co-ordinated as to form six departments; two academic—the college and the department of graduate studies; and four professional—law, medicine, engineering and education. The institution owns (1928) 522 acres of land, has productive endowment funds amounting to $10,000,000, and receives from the State an annual appropriation of $400,000. The total budget of the university for 1927 was $1,363,000. It is governed by a rector, chosen by and from nine visitors, and a board of visitors appointed by the governor, and two visitors *ex officio*, the State superintendent of public instruction and the president of the university. The corporate name of the university is "The Rector and Visitors of the University of Virginia." In 1927 the faculty and officers numbered 257, the students 2,174 (2,056 men, 118 women), and the number of volumes in the libraries 200,000.

The university traces its beginning to an act of the legislature in January 1803 for incorporating the "Trustees of Albemarle academy." In 1814, before the site of this proposed institution had been chosen, Thomas Jefferson was elected a trustee, and under his influence the legislature, in February 1816, authorized the establishment of Central college in lieu of Albemarle academy. The corner-stone of Central college was laid in October 1817, and Jefferson, who was rector of its board of trustees, evolved a plan for its development into the University of Virginia. The legislature, thanks to the efforts of Joseph Carrington Cabell, a close personal friend of Jefferson, adopted the plan in 1818 and 1819, and seven independent schools—ancient languages, modern languages, mathematics, natural philosophy, moral philosophy, chemistry and medicine—were opened to students in March 1825. A school of law was opened in 1826. In 1837 the School of Medicine became a department of three individual schools; and in 1850 the School of Law became a department of two schools. After the gift of $500,000 by Andrew Carnegie there were established in 1909 the Andrew Carnegie School of Engineering, the James Madison School of Law, the James Monroe School of International Law, the James Wilson School of Political Economy, the Edgar Allan Poe School of English and the Walter Reed School of Pathology.

Under Jefferson's plan only two degrees were granted: "Graduate" to any student who had completed the course of any one school; and "Doctor" to a graduate in more than one school who had shown powers of research. But in 1831, for the doctor's degree the faculty substituted, following British custom, the degree of Master of Arts. The college now grants the customary university degrees.

See J. S. Patton, *Jefferson, Cabell and the University of Virginia* (1906). (E. A. Al.)

VIRGINIA COWSLIP (*Mertensia virginica*), a North American plant of the borage family (Boraginaceae), called also bluebells, Roanoke-bells, and tree-lungwort. It grows in low meadows and in open woods along streams from New York and Ontario to Minnesota and southward to South Carolina and Kansas. The plant is a smooth perennial, with a usually erect simple or somewhat branching stem, 1 ft. to 2 ft. high, with large, oblong, long-stalked, very veiny basal leaves. In early spring it bears at the top of the stem showy clusters of blue-purple flowers. These are pink in the bud but when expanded are about an inch long and trumpet-shaped, with a purple tube and a blue bell. This beautiful plant, one of the most popular wild flowers of the eastern States, transplants well and is often cultivated. *See* Boraginaceae; Mertensia.

VIRGINIA CREEPER (*Parthenocissus*), a well-known genus of climbing plants, containing ten species in temperate Asia and America, of which *P. tricuspidata*, native to China and Japan, and *P. quinquefolia*, of eastern North America, are cultivated. *Parthenocissus* belongs to the family Vitaceae and climbs by means of sucker-like tendrils. The leaves are split into leaflets, *P. tricuspidata* (Boston ivy) having three, and *P. quinquefolia* (Virginia creeper) five. The beautiful reds and yellows assumed by the leaves in autumn add to the attractiveness of the plants, which are commonly grown for covering walls.

VIRGINIA REEL, a lively American country-dance, formerly very popular in the United States, derived from the Sir Roger de Coverley. Originally intended for six couples only, in longways formation, it later became common practice to form in one long set, the men and women in separate lines facing each other. The steps include the usual country-dance, march and galop steps, best danced to the music of the violin, with the fiddler "calling" the figures, the partners advancing and swinging each other and other couples in turn, in a pattern in which the reel is most prominent.

VIRGIN ISLANDS, a group of small islands in the West Indies, about 100 in number, mostly uninhabited. They extend E. from Porto Rico, lying between 17° and 18° 50′ N., and 64° 10′ and 65° 30′ W.: total area about 465 sq.m. The islands are rocky, or sandy and barren, but the cultivated portions yield cotton, sugar and the usual W. Indian food-crops. Guinea grass grows abundantly on the hillsides, and good cattle are reared. The coasts abound with fish. The climate is healthy and the heat moderate. Culebra and Vieques or Crab Islands were acquired by the United States from Spain in 1898 with Porto Rico.

Of the British Islands, 32 in all with an area of 58 sq.m., the principal are Tortola, Anegada, Virgin Gorda, Jost van Dyke, Peter's Island and Salt Island. With the exception of the island of Sombrero they form one of the five presidencies in the colony of the Leeward Islands. The inhabitants are peasants who raise cattle and burn charcoal. Some are fishermen and boatmen. The chief town is Roadtown (pop. 400) at the head of a fine harbour on the S. of Tortola, and trade is mostly with St. Thomas. Sombrero is maintained as a lighthouse by the British government. Population of the presidency, mostly negroes (1921) 5,082.

The Virgin Islands were discovered by Columbus in his second voyage, in 1493, and named Las Virgenes, in honour of St. Ursula and her companions. In 1666 the British occupied Tortola, and

VIEWS OF TOWN ON ISLAND OF ST. THOMAS

1. Looking down from the top of Mafolie Hill on the harbour and city of St. Thomas. St. Thomas island is the most important of the three Virgin Islands, formerly the Danish West Indies, which were purchased by the United States in 1917. 2. Negro men and women coaling ships in the harbour of St. Thomas. Because of its central position on the route from Europe through the Panama Canal to the countries on the Pacific, this harbour is used extensively as a coaling station. 3. View of St. Thomas showing the clock tower of Fort Christian, now used as a police station and prison. On the hill in the background, the old tower known as "Bluebeard's Castle" supposed to have belonged to the Bluebeard of the Seven Wives of Perrault's fairy tale. 4. Eastern end of city of St. Thomas, the only city on the Island of St. Thomas. Picturesquely situated on the spur of three mountains, it is a modern well-kept city. Its principal revenue is derived from ships which dock for coaling and repairs

have held it ever since. In the 17th century the Virgin Islands were favourite resorts of the buccaneers. The islands of St. Thomas and St. John were taken by the British from Denmark in 1801, but restored in the following year. In 1807 they surrendered to the British, and continued in their hands till 1815, when they were again restored.

In 1917, after various unsuccessful negotiations begun before 1867, the three islands, St. Croix, St. Thomas and St. John, were brought from Denmark by the United States of America for $25,000,000. St. Thomas and St. John form one administrative municipality, St. Croix another and each has a local legislative council. The inhabitants of these islands have become (1927) citizens of the United States. They numbered 26,051 in 1917 and 20,728 in 1927, the decrease being largely due to emigration to the United States. In 1917, 92·6% of the population was negro, or coloured. The combined area of the American islands is 132·47 sq.m. In 1927 the police census gave St. Croix 11,118, St. Thomas 8,826 and St. John 784 inhabitants. Charlotte Amalie (now St. Thomas), with a population of 7,747 in 1917, is the largest town and the seat of government; it has a fine harbour and is 1,442 m. from New York and 1,029 m. from the Panama canal. Administrative officers for the islands are appointed by the United States Navy Department. St. Croix (towns Christiansted and Fredericksted) produces sugar, molasses and hides. St. John and St. Thomas have little agriculture, but from the *Pimenta acris* is produced bay-oil and bay rum. The export of bay rum in 1927 totalled 60,494 gallons.

VIRGINIUS RUFUS, LUCIUS (A.D. 15–97), Roman soldier, three times consul (A.D. 63, 69, 97), was born near Comum. When governor of upper Germany under Nero (68), after he had put down the revolt of Iulius Vindex in Gaul, he was urged by his troops to assume the supreme power; but he refused, declaring that he would recognize no one as emperor who had not been chosen by the senate. Galba, on his accession, aware of the feelings of the German troops induced Virginius to accompany him to Rome. After the death of Otho, the soldiers again offered the throne to Virginius, but he again refused it. They then attacked him, and he had to escape through the back of his tent. Under Vitellius, one of Virginius's slaves was arrested and charged with the design of murdering the emperor. Virginius was accused of being implicated in the conspiracy, and his death was demanded by the soldiers. Vitellius refused to sacrifice him to the army's resentment, and Virginius subsequently lived in retirement, chiefly in his villa at Alsium, on the coast of Etruria, till his death in 97, in which year he held the consulship, together with the emperor Nerva. At the public burial with which he was honoured, the historian Tacitus (then consul) delivered the funeral oration.

See Tacitus, *Hist.* i. ii.; Dio Cassius lxiii. 24–27, lxiv. 4, lxviii. 2; Pliny, *Epp.* ii. 1, vi. 10; Juvenal viii. 221, with Mayor's note; L. Paul in *Rheinisches Museum* (1899), liv. pp. 602–30.

VIRGO ("the virgin"), in astronomy, the sixth sign of the zodiac, denoted by the symbol ♍. The Greeks represented this constellation as a virgin, but different fables are current as to the identity of the maid. She is variously considered to be: Iustitia, daughter of Astraeus and Ancora, who lived before man sinned, and taught him his duty, and who when the golden age ended returned to heaven; according to Hesiod the virgin is the daughter of Jupiter and Themis; others make her to be Erigone, daughter of Icarius, or Parthene, daughter of Apollo. The constellation contains a first magnitude star, Spica.

VIRTUE: *see* CARDINAL VIRTUES.

VIS, an island in the Adriatic, forming part of Dalmatia, Yugoslavia (Italian, *Lissa*). Pop. (1921) 5,139, divided between two villages. In Vis, the capital, which has an excellent harbour, is the old palace of the Counts Gariboldi, the monastery of the Minorites, several large churches and a hotel. The chief industries are viticulture, the distillation of rosemary oil, and sardine fishing. Komiža, the other village, has a large sardine factory. The grotto on the island of Biševo (Italian *Busi*) is said to be finer than that of Capri. Iron ore is found on the island. To the west of the capital lie the ruins of the ancient city of Issa, traditionally founded by settlers from Lesbos, the Issa of the Aegean. The Parians introduced a colony in the 4th century B.C. During the first Punic War (265–41 B.C.) the Issaeans helped the Romans, who in turn defended them from the Illyrians. Later, when Illyria became a Roman province, Vis was incorporated in it, and many Roman remains have been found on the island. Still later, it was ravaged by the pirates of Almissa, taken by Venice in 996, then captured by the Ragusans, but in 1278 Venice had re-established herself there. Velo Selo, then the chief settlement, was destroyed by Ferdinand of Naples in 1483, and by the Turks in 1571. The present city rose shortly afterwards. During the Napoleonic wars the French held Vis until 1811, and by the cheap sale of captured merchandise, brought prosperity to the islanders, and the trebling of its population. In 1811 the French were defeated by the British and thenceforward the island smuggled British goods into Dalmatia. In 1812 the British established an administrative system under native officials, in Vis and the adjoining islands of Korčula and Lagosta. They built a line of forts along the heights of Vis, and made a cemetery for the sailors killed during the Napoleonic wars. Twenty years later the Italians bombarded Vis during the War of Liberation, but were defeated in a naval engagement with the Austrians, who had held the island since 1815. At the close of the World War (1914–18) the Italians occupied it.

VISALIA, a city of south-central California, U.S.A., 160 m. N. by E. of Los Angeles; the county seat of Tulare county. It has a municipal airport, and is served by the Santa Fe, the Southern Pacific and electric railways, and motor-coach lines. Pop. (1920) 5,753 (85% native white); 1928 local estimate, more than 8,600. It is the trading centre and shipping point for a rich farming, dairying and poultry-raising region, where fruits, vegetables and other agricultural products (including cotton) are grown in great variety. Thirty miles east is the Sequoia National park of 604 sq.m., containing over 1,000,000 trees, 12,000 of which are 10 ft. or more in diameter. Visalia was founded in 1852 and incorporated in 1874.

VISBY, the capital of the Swedish island and administrative district (*län*) of Gottland, in the Baltic sea. Pop. (1927) 10,103. The name Visby is derived from the old Norse *ve* (sanctuary) and *by* (town). This was no doubt a place of religious sacrifice in heathen times. At any rate it was a notable trading-place and emporium as early as the end of the Stone Age, and long continued to enjoy its importance as such, as is proved by the large number of Arabic, Anglo-Saxon and other coins found.

Visby is the seat of a bishop, the port of the island, and a favourite watering-place. It is picturesquely situated on the west coast, 150 m. S. by E. of Stockholm by sea. The houses cluster beneath and above a cliff (*klint*) 100 ft. high, and the town is thoroughly mediaeval in appearance. The remains from its period of extraordinary prosperity from the 11th to the 14th century are of the highest interest. Its walls date from the end of the 13th century, replacing earlier fortifications, and enclose a space much larger than that now covered by the town. Massive towers rise at close intervals along them, and nearly forty are in good preservation. Between them are traces of bartizans. The cathedral church of St. Mary dates from 1190–1225, but has been much altered in later times; it has a great square tower at the west end and two graceful octagonal towers at the east, and contains numerous memorials of the 17th century. There are ten other churches, in part ruined. Among those of chief interest St. Nicholas', of the early part of the 13th century, formerly belonged to a Dominican monastery. It retains two beautiful rose-windows in the west front. The church of the Holy Ghost (*Helgeands-Kyrka*) in a late Romanesque style (*c.* 1250) is a remarkable structure with a nave of two storeys. The Romanesque St. Clement's has an ornate south portal, and the churches of St. Drotten and St. Lars, of the 12th century, are notable for their huge towers. St. Catherine's, of the middle of the 13th century, is Gothic, with a pentagonal apse. Galgberget, the place of execution, has tall stone pillars still standing; and there is a stone labyrinth at Tröjeborg. Modern buildings include the Gottland museum of antiquities. The artificial harbour, somewhat exposed, lies south of the ancient Hanseatic harbour, now filled up. *See* GOTTLAND and SEA LAWS.

VISCACHA or **BISCACHA,** a large South American burrowing rodent belonging to the family Chinchillidae. The viscacha (*Viscaccia*) is distinguished from the other members of that group by having only three hind toes; it is the heaviest-built and largest member with smaller ears than the rest. It has a long tail and shaggy fur; the general colour of the latter being dark grey, with black and white markings on the face. Viscachas inhabit the South American pampas between the Uruguay river and the Rio Negro in Patagonia, where they dwell in warrens covering from 100 to 200 sq.ft. and forming mounds penetrated by numerous burrows. The ground around the "viscachera" is cleared from vegetation, the refuse of which is heaped upon the mound. Anything the rodents meet with on their journeys, such as thistle-stalks or bones, are deposited on the viscachera. In frequented districts they seldom emerge till evening. Their chief food is grass and seeds, but they also consume roots. (*See* RODENTIA.)

VISCERAL SENSATIONS, the sensations that arise from the viscera and other internal bodily organs and tissues. The visceral sensations belong to the general class of organic sensations (*q.v.*) and are distinguished among them only by the seat of their origin. They are characterized by their paucity of qualitative variety and by their functional importance in consciousness. On the side of quality they include only cold and warmth, and the dull pressures and the aches that come from muscle and other tissue beneath the skin. (*Cf.* CUTANEOUS SENSATIONS.) On the side of function they constitute the sensory basis for many of the vague awarenesses or "conscious attitudes" that are ever present in the mental life. For instance, recognition is a perception coloured by a feeling of familiarity, and this feeling often has its seat in the viscera although it has no fixed sensory basis. Visceral sensations are also functionally important as carrying much of the conscious organic reverberation that is characteristic of strong emotion.

The oesophagus and stomach are sensitive to pressure on distension and to ache on extreme distension, as well as to warmth and to cold. This fact can be brought out only by research, because the stomach is ordinarily not often distended without distension of the bodily walls and is altered appreciably in temperature only by large quantities of hot or cold material. The common belief in the insensitivity of the oesophagus comes about because its sensations are ordinarily localized as above or below the bony chest wall, *i.e.*, either in the throat or in the stomach. The intestines are less accessible to experimentation, but it is probable that they are sensitive to pressure and pain like the stomach, but that excitation of these sensations is rare.

It is well known that in surgical operations the viscera appear to be almost entirely insensitive. The meaning of this finding is that cutting and ordinary pressure are not adequate stimuli to the sensations that they arouse on the skin. Apparently distension or muscular contraction of the viscera themselves are the proper stimuli. The peritoneum, its extension in the mesentery, and possibly the pleura are very sensitive to pain, even upon cutting.

The more usual attack upon the problem of visceral sensations has been by way of the perceptions which they mediate. These perceptions seem to involve no unique qualities, but nevertheless to carry very specific significance for the organism. Thirst arises from dryness of the membranes of the oral cavity, and is ordinarily caused by a lack of water in the system. It is no more a new quality than is the perception of dryness on the skin. Hunger is an ache of a peculiar temporal pattern, for it is caused by certain slow rhythmic contractions of the stomach that appear in the absence of stomachic contents or at regular intervals by habit. Any substance introduced into the stomach to inhibit these contractions abolishes hunger. The alimentary experiences of fullness, repletion and nausea, and the experiences of the excretory processes, are simply internal perceptions, in terms of pressure or pain, of the states or processes to which they correspond. Appetite is the desire for food in the absence of hunger, and is ordinarily associated with all normal food-taking, since the first food that enters the stomach inhibits the hunger contractions. Appetite, however, seems to have no peculiar sensory or perceptual basis at all. Its mechanism is purely unconscious as in the instincts and habits, although of course the eater perceives his desire for food by perceiving his behaviour toward it. Some psychologists have thought that there are sensations of oppression from the heart and of stuffiness from the lungs, but the matter remains undetermined. Sexual experience involves unique perceptual patterns of pressure and pain. Like appetite, however, the psychology of sex is best understood functionally as an instinctive urge and a form of behaviour, although to the individual the earlier perceptions of bodily state may seem to be the causes of subsequent behaviour. That emotion involves visceral sensations is well known, but we are still ignorant of their degree and nature, although a great deal is now known of the visceral state during emotion (*q.v.*).

(E. G. BOR.)

VISCHER, the name of a family of Nuremberg sculptors, who contributed largely to the masterpieces of German art in the 15th and 16th centuries.

1. HERMANN, the elder, came to Nuremberg as a worker in brass in 1453 and there became a "master" of his gild. There is only one work that can be ascribed to him with certainty, the baptismal font in the parish church of Wittenberg (1457). This is decorated with figures of the Apostles.

2. His son, PETER, the elder, was born about 1455 in Nuremberg, where he died on the 7th of January 1529. He became "master" in 1489, and in 1494 was summoned by the Electoral Prince Philipp of the Palatinate to Heidelberg. He soon returned, however, to Nuremberg, where he worked with the help of his five sons, Hermann, Peter, Hans, Jakob and Paul. His works are: the tomb of Bishop Johannes IV., in the Breslau cathedral (1496); the tomb of Archbishop Ernest, in Magdeburg cathedral (1497); the shrine of Saint Sebald in the Sebalduskirche at Nuremberg, between 1508 and 1519; a large grille ordered by the Fugger brothers in Augsburg (lost); a relief of the "Crowning of the Blessed Virgin" in the Erfurt cathedral (a second example in the Wittenberg Schlosskirche, 1521); the tombstones for Margareta Tucherin the Regensburg cathedral (1521), and for the Eisen family in the Ägidienkirche at Nuremberg (1522); the epitaph for the cardinal Albrecht of Brandenburg in the collegiate church at Aschaffenburg (1525); the tomb of the electoral prince Frederick the Wise in the Schlosskirche at Wittenberg (1521); the epitaph of the duchess Helene of Mecklenburg in the cathedral at Schwerin. Besides these works there are a number of others ascribed to Peter the elder with less certainty. In technique few bronze sculptors have ever equalled him, but his designs are marred by an excess of realism and a too exuberant fancy.

His chief early work, the tomb of Archbishop Ernest in Magdeburg cathedral (1495), is surrounded with fine statuettes of the Apostles under semi-Gothic canopies; it is purer in style than the magnificent shrine of St. Sebald, a tall canopied bronze structure, lavishly decorated with reliefs and statuettes. The general form of the shrine is Gothic, but the details are those of the 16th-century Italian Renaissance treated with much freedom and originality. Some of the statuettes of saints attached to the slender columns of the canopy are modelled with much grace and even dignity of form. A small portrait figure of Peter himself, introduced at one end of the base, is a marvel of clever realism: he has represented himself as a stout, bearded man, wearing a large leathern apron and holding some of the tools of his craft. This gorgeous shrine is a remarkable example of the uncommercial spirit which animated the artists of that time, and of the evident delight which they took in their work. Dragons, grotesques and little figures of boys, mixed with graceful scroll foliage, crowd every possible part of the canopy and its shafts, designed in the most free and unconventional way and executed with an utter disregard of the time and labour which were lavished on them.

See R. Bauer, *Peter Vischer und das alte Nürnberg* (1886); C. Headlam, *Peter Vischer* (1901).

VISCHER, FRIEDRICH THEODOR (1807–1887), German writer on the philosophy of art, was born at Ludwigsburg on June 30, 1807, the son of a clergyman. He was educated at Tübingen, and began life in his father's profession. In 1835 he became *Privatdozent* in aesthetics and German literature at his old university, was advanced in 1837 to extraordinary professor, and in 1844 to full professor. In consequence, however, of his outspoken inaugural address, he was suspended for two years by the Württemberg government, and in his enforced leisure wrote the first two volumes of his *Aesthetik oder Wissenschaft des Schönen* (1846), the fourth and last volume of which did not appear till 1857. Vischer threw himself heartily into the great German political movement of 1848–49, and shared the disappointment of patriotic democrats at its failure. In 1855 he became professor at Zürich. In 1866, his fame being now established, he was invited back to Germany with a professorship at Tübingen combined with a post at the Polytechnikum of Stuttgart. He died at Gmunden on Sept. 14, 1887.

Vischer was not an original thinker, and his monumental *Aesthetik*, in spite of industry and learning, has not the higher qualities of success. Still, he had a thorough knowledge of every branch of art except music, and much valuable material is buried in his volumes.

His writings include literary essays collected under the titles *Kritische Gänge* and *Altes und Neues*, poems, an excellent critical study of Goethe's *Faust* (1875), and a successful novel, *Auch Einer* (1878; 25th ed., 1904).

See O. Keindl, *F. T. Vischer, Erinnerungsblätter* (1888); J. E. von Günthert, *F. T. Vischer, ein Charakterbild* (1888); I. Frapan, *Vischer-Erinnerungen* (1889); T. Ziegler *F. T. Vischer* (*Vortrag*) (1893); J. G. Oswald, *F. T. Vischer als Dichter* (1896).

VISCONTI, the name of a celebrated Italian family which long ruled Milan; they claimed descent from King Desiderius, and in the 11th century possessed estates on Lakes Como and Maggiore. A certain OTTONE, who distinguished himself in the First Crusade, is mentioned in 1078 as viscount of Milan. The real basis for the family's dominion was laid, however, by another OTTONE (d. 1295), a canon of Desio, appointed archbishop of Milan by Pope Urban IV. in 1262 through the influence of Cardinal Ubaldini. The Della Torre family, who then controlled the city, opposed the appointment, and not until his victory at Desio in 1277 was Ottone able to take possession of his see. He imprisoned Napoleone Della Torre and five of his relatives.

His nephew, MATTEO, born at Invorio on Aug. 15, 1255, succeeded him as political leader of Milan, and although an uprising of the Della Torre in 1302 compelled him to take refuge at Verona, the emperor Henry VII., restored him to Milan in 1310 and made him imperial vicar of Lombardy. He brought under his rule Piacenza, Tortona, Pavia, Bergamo, Vercelli, Cremona and Alessandro. An able general, he yet relied for his conquests more on diplomacy and bribery, and was esteemed as a model of the prudent Italian despot. Persevering in his Ghibelline policy, and quarrelling with Pope John XXII. over an appointment to the archbishopric of Milan, he was excommunicated by the papal legate Bertrand du Puy in 1322. He at once abdicated in favour of his son Galeazzo, and died at Crescenzago on June 24.

GALEAZZO I. (1277–1328), who ruled at Milan from 1322 to 1328, defeated the Holy Army which the pope had sent against the Visconti at Vaprio on the Adda (1324), with the aid of the emperor Louis the Bavarian. In 1327 he was imprisoned for a short time by the emperor at Monza because he was thought guilty of making peace with the church. By his wife Beatrice d'Este he had the son Azzo who succeeded him. His brother MARCO commanded a band of Germans, conquered Pisa and Lucca and died in 1329. AZZO (1302–1339), who succeeded his father in 1328, bought the title of imperial vicar for 25,000 florins from the same Louis who had imprisoned Galeazzo I. He conquered ten towns, murdered his uncle Marco (1329), suppressed a revolt led by his cousin Lodrisio, reorganized the administration of his estates, built the octagonal tower of S. Gottardo, and was succeeded in turn by his uncles Lucchino and Giovanni. LUCCHINO made peace with the church in 1341, bought Parma from Obizzo d'Este and made Pisa dependent on Milan. He was poisoned in 1349 by his wife Isabella Fieschi.

GIOVANNI, brother of the preceding, archbishop of Milan and lord of the city from 1349 to 1354, was one of the most notable characters of his time. He befriended Petrarch, extended the Visconti sway over Bologna (1350), defied Pope Clement VI., annexed Genoa (1353), and died on Oct. 5, 1354, after having established the rule of his family over the whole of northern Italy except Piedmont, Verona, Mantua, Ferrara and Venice. The Visconti from the time of Archbishop Giovanni were no longer mere rivals of the Della Torre or dependants on imperial caprice, but real sovereigns with a recognized power over Milan and the surrounding territory. The State was partitioned on the death of Giovanni among his brother Stefano's three sons, Matteo II., Galeazzo II. and Bernabo. MATTEO II., who succeeded to Bologna, Lodi, Piacenza and Parma, abandoned himself to the most revolting immorality, and was assassinated in 1355 by direction of his brothers, who thenceforth governed the State jointly and with considerable ability. GALEAZZO II., who held his court at Pavia, was the patron of Petrarch, the founder of the University of Pavia, and a gifted diplomat. He married his daughter Violante to the duke of Clarence, son of Edward III. of England, giving a dowry of 200,000 gold florins; and his son Gian Galeazzo to Isabella, daughter of King John of France. He died in 1378. BERNABO, who held his court at Milan, was involved in constant warfare, to defray the expenses of which he instituted very oppressive taxes. He fought Popes Innocent VI. and Urban V., who proclaimed a crusade against him, and the emperor Charles IV., who declared the forfeiture of his fief. He endeavoured to exercise sole power in the State after the death of his brother, but his young nephew Gian Galeazzo put him to death (1385).

GIAN GALEAZZO, the most powerful of the Visconti, became joint ruler of the Milanese territories on the death of his father in 1378 and sole ruler on the death of his uncle seven years later. He founded the cathedral of Milan, built the Certosa and the bridge across the Ticino at Pavia, improved the University of Pavia and established the library there, and restored the university at Piacenza. He was an able and economical administrator, and was reputed to be one of the wealthiest princes of his time. Ambitious to reduce all Italy under the sway of the Visconti, he conquered Verona in 1387; and in the following year, with the aid of the Venetians, took Padua. He plotted successfully against the rulers of Mantua and Ferrara, and finally turned his attention to Tuscany. In 1399 he bought Pisa and seized Siena. The emperor Wenceslaus had already conferred on him the title of duke of Milan for 100,000 florins, reserving only Pisa, and refused to take arms against him. Gian Galeazzo took Perugia, Lucca and Bologna (1400–01), and was besieging Florence when he died of the plague (Sept. 3, 1402). His sons, Giovanni Maria and Filippo Maria, were mere boys at the time of his death, and were taken under the protection of the celebrated condottiere Facino Cane de Cesale; but most of Gian Galeazzo's conquests were lost.

GIOVANNI MARIA was proclaimed duke of Milan in 1402, displayed an insane cruelty, and was killed in 1412 by Ghibelline partisans. FILIPPO MARIA, who became nominal ruler of Pavia in 1402, succeeded his brother as duke of Milan. Cruel and extremely sensitive about his personal ugliness, he nevertheless was a great politician, and, by employing powerful condottieri, managed to recover the Lombard portion of his father's duchy. From his marriage with the unhappy widow of the above-mentioned Facino Cane he received a dowry of nearly half a million florins. He died in 1447, the last of the Visconti in direct male line, and was succeeded in the duchy, after the shortlived Ambrosian republic, by Francesco Sforza, who had married his daughter Bianca in 1441. (*See* SFORZA.)

There is a contemporary history of the principal members of the family by Paolo Giovio, bishop of Nocera, which may be had in several editions. *See* J. VISCONTI-VENOSTA, EMILIO, MARQUIS (1829–1914), Italian statesman, was born at Milan on Jan. 22, 1829. A disciple of Mazzini, he took part in all the anti-Austrian conspiracies until the ineffectual rising at Milan on Feb. 6, 1853, of which he had foretold the failure, induced him to renounce his Mazzinian allegiance. Continuing, nevertheless, his anti-Austrian propaganda, he rendered good service to the national cause. He was obliged in 1859 to escape to Turin, and during the war with Austria of that year was appointed by Cavour royal commissioner with the Garibaldian forces. Elected deputy in 1860, he accompanied Farini on diplomatic missions to Modena and Naples, and was subsequently despatched to London and Paris to acquaint the British and French Governments with the course of events in Italy. Cavour gave him a permanent appointment in the Italian foreign office, and he was subsequently appointed under-secretary of State by Count Pasolini. Upon the latter's death he became minister of foreign affairs (March 24, 1863) in the Minghetti cabinet, in which capacity he negotiated the September Convention for the evacuation of Rome by the French troops. Resigning office with Minghetti in the autumn of 1864, he was in March 1866 sent by La Marmora as minister to Constantinople, but was almost immediately recalled and reappointed foreign minister by Ricasoli. Assuming office on the morrow of the second battle of Custozza, he succeeded in preventing Austria from burdening Italy with a proportion of the Austrian imperial debt, in addition to the Venetian debt proper. The fall of Ricasoli in Feb. 1867 deprived him for a time of his office, but in Dec. 1869 he entered the Lanza-Sella cabinet as foreign minister, and retained his portfolio in the succeeding Minghetti cabinet until the fall of the Right in 1876. During this long period he was called upon to conduct the delicate negotiations connected with the Franco-German War, the occupation of Rome by the Italians, and the consequent destruction of the temporal power of the pope, the Law of Guarantees and the visits of Victor Emmanuel II. to Vienna and Berlin. In 1894, after 18 years' absence from active political life, he was chosen to be Italian arbitrator in the Bering Sea question, and in 1896 once more became foreign minister in the Di Rudini cabinet at a juncture when the disasters in Abyssinia and the indiscreet publication of an Abyssinian Green Book had rendered the international position of Italy exceedingly difficult. His first care was to improve Franco-Italian relations by negotiating with France a treaty with regard to Tunis. During the negotiations relating to the Cretan question and the Graeco-Turkish War, he secured for Italy a worthy part in the European Concert, and joined Lord Salisbury in saving Greece from the loss of Thessaly. Resigning office in May 1898, on a question of internal policy, he once more retired to private life, but in May 1899 again assumed the management of foreign affairs in the second Pelloux cabinet, and continued to hold office in the succeeding Saracco cabinet until its fall in Feb. 1901. During this period his attention was devoted chiefly to the Chinese problem and to the maintenance of the equilibrium in the Mediterranean and in the Adriatic. In regard to the Mediterranean he established an Italo-French agreement, by which France undertook to leave Italy a free hand in Tripoli, and Italy not to interfere with French policy in the interior of Morocco. Prudence and sagacity, coupled with unequalled experience of foreign policy, enabled him to assure to Italy her full portion of influence in international affairs, and secured for himself the unanimous esteem of European cabinets. In recognition of his services he was created Knight of the Annunziata by Victor Emmanuel III. on the occasion of the birth of Princess Yolanda Margherita of Savoy (June 1, 1901). In Feb. 1906 he was Italian delegate to the Morocco conference at Algeciras. After this he retired into private life. He died in Rome on Nov. 28, 1914.

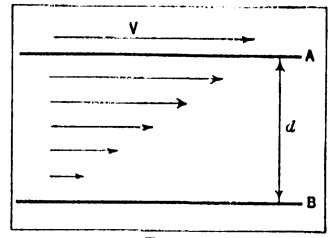
An account of Visconti-Venosta's early life (down to 1859) is given in an interesting volume by his brother Giovanni Visconti-Venosta, *Ricordi di Gioventù* (Milan, 1904).

VISCOSE. In 1928, nearly nine-tenths of the world's entire output of artificial silk was based on the sodium xanthogenite ester known as viscose. For particulars of the process *see* ARTIFICIAL SILK and CELLULOSE.

VISCOSITY. All bodies, whether solids, liquids or gases, oppose a resistance to deformation or relative displacement of portions of the body against one another. This resistance may be of different kinds; it may, for instance, increase as the velocity with which parallel planes a fixed distance apart are displaced relatively to each other increases, and in that case, which is of great importance in nature, it is said to be due to viscosity. The definition will become clearer when we consider the viscosity of liquids, which is readily observed and was the first in point of time to be investigated both mathematically and experimentally.



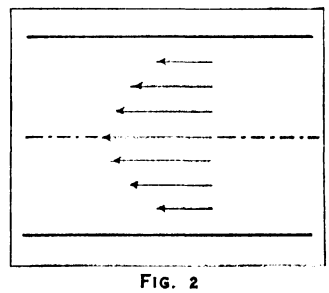


FIG. 1

The Viscosity of Liquids.—We imagine two indefinitely extended parallel plates A and B (fig. 1) between which a liquid is contained, and keep plate A moving in its own plane with a constant velocity v, indicated by the length of the arrow, while plate B remains at rest. The liquid in contact with A moves with it, while that in contact with B stands still; as the velocity in the liquid changes continuously, we can imagine it to consist of thin sheets or laminae, each moving with the velocity indicated by the arrows in fig. 1. A certain force must be applied to A to keep the velocity v constant, and Newton made the assumption that this force was proportional to the area of the plates and to the velocity with which adjoining laminae passed over each other, in other words to the velocity gradient, v/d. These assumptions are purely intuitive, but all subsequent investigations have fully confirmed them. Other things being equal, the force varies greatly in different liquids, and to make comparison possible, it is usual to state the force required per unit area to keep A moving with unit velocity when d = unit distance and the space between the plates is filled with a particular liquid; this quantity is called the coefficient of viscosity of the liquid. The units generally employed in physics for force, length and time are used to express viscosity coefficients, viz., the dyne, centimetre and second.

Two parallel plates with a liquid between them constitute an arrangement from which we can easily deduce a definition of the viscosity coefficient, but one which cannot be realized experimentally. Arrangements are, however, possible which fulfil the essential condition that the liquid should behave as if it consisted of thin laminae each moving with a constant velocity—a type of motion which is, for that reason, called "laminar." We can, for instance, "roll up" the two parallel planes of fig. 1 into two concentric cylinders and rotate the outer one with constant velocity, while the inner one is at rest (fig. 2). Each circle in the ring of liquid then rotates with a constant velocity; the inner cylinder tends to follow the motion and from the torque exerted on it the coefficient of viscosity can be deduced.

FIG. 2

Laminar motion is also set up when a liquid flows through a cylindrical tube of small bore and sufficient length, as long as the velocity does not exceed a certain limit. The liquid flows as if it consisted of thin concentric tubes, each moving with a constant velocity which increases from the wall towards the axis (fig. 3). The coefficient of viscosity can be deduced from the dimensions of the tube and the quantity of liquid forced through it in unit time by a known pressure.

It is, finally, possible to determine the coefficient of viscosity of a liquid by observing the velocity with which a small sphere of known diameter and mass falls in it. It was shown by Stokes that a small sphere falling in a viscous medium soon attains a constant velocity (in a medium offering no resistance its velocity is uniformly accelerated) given by the following equation:

$$v = \frac{2r^2(\rho - \rho')g}{9\eta}$$

in which the symbols mean: v the velocity of fall per second, r the radius of the sphere, ρ and ρ' the density of the sphere and of the liquid respectively, g the acceleration of gravity = 981 cm/sec^2 and η the coefficient of viscosity. Other things being equal, the coefficient of viscosity and the velocity of fall are inversely proportional.

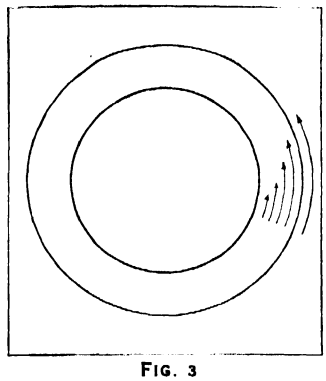

FIG. 3

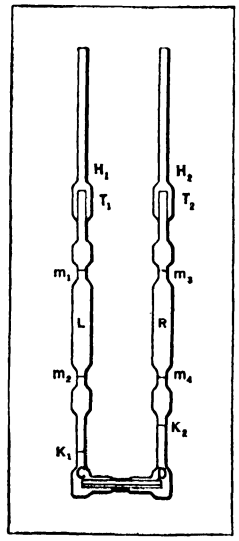
Measuring the flow through a capillary tube was the first method used for determining viscosities, and is still the most generally employed. The law governing the flow through capillaries was found experimentally by Poiseuille in a classical investigation published in 1842. He found that the volume of liquid which passed through a capillary in unit time was (1) proportional to the pressure, (2) proportional to the fourth power of the radius and (3) inversely proportional to the length of the tube. In symbols, if Q = volume discharged in unit time, P = pressure, R = radius and L = length of the tube:

$$Q = C\frac{PR^4}{L}$$



where C is a constant characteristic for each liquid, which always increases with rising temperature. Poiseuille did not deduce coefficients of viscosity, but this was done by several physicists who treated the problem mathematically by working out the conditions of flow for one of the elementary tubes described above and integrating; the equation thus obtained is known as Poiseuille's formula:

$$Q = \frac{\pi PR^4}{8\eta L}$$

where η is the coefficient of viscosity, which can therefore be calculated from Poiseuille's experimental data. As has been mentioned, the coefficient of viscosity is expressed in cm-gm-sec units; the coefficient η = 1·000 in these units is called a *poise* (in honour of Poiseuille) and its hundredth part a *centipoise*. The viscosity coefficient of water at 20° C. is almost exactly a centipoise.

A convenient alternative method of expressing the viscosity η_1 of a liquid is to state the ratio η_1/η_0, where η_0 is the viscosity of a suitably chosen standard liquid; this ratio is called the relative viscosity.

Capillary Viscometers.—A number of instruments have been designed for measuring viscosity by means of the flow through a capillary; they all have this in common, that a constant volume, defined by suitable marks, is forced through a capillary by a known pressure. A type of historical interest is that used by Thorpe and Rodger in a famous investigation on a large number of pure organic liquids (fig. 4). CD is the capillary, the bore and length of which are accurately known. A definite volume of liquid is introduced into the right hand limb with a fine pipette reaching down to R; air pressure is then applied to the left hand limb, until the liquid stands at K, any excess at the same time overflowing into the trap T_2. A known pressure, measured by a water manometer, is then applied to the right limb, and the time which the liquid takes to fall from the mark m_3 to the mark m_4 measured by a stop watch reading to ⅕ second. The liquid is then forced up the opposite limb, the procedure reversed and the time from m_1 to m_2 taken; the two times are averaged. The volumes L and R between the marks are accurately known, and from them, the times, pressures and dimensions of the capillary; the viscosity coefficients in absolute measure are calculated by Poiseuille's formula.

FROM THORPE & RODGERS, IN "PHILOSOPHICAL TRANSACTIONS" (COUNCIL OF THE ROYAL SOCIETY)

FIG. 4

In another instrument, designed by Wilhelm Ostwald and called after him, which is very generally used, the pressure producing the flow is produced simply by the column of liquid itself (fig. 5). A constant volume of liquid is charged into the wide limb from a pipette and is drawn through the capillary into the bulb well above the mark A; it is then allowed to flow out and the time between the marks A and B is taken with a stop watch. This is done once and for all for a standard liquid, the viscosity η_0 and density ρ_0 of which, at a convenient temperature, are accurately known; the time t_0 is found as the average of several determinations.

As the same volume of liquid is always used, the effective column of liquid is always of the same height, so that the pressures producing the flow are directly proportional to the densities. If therefore the time of efflux for another liquid of density ρ_1 is found to be t_1 its viscosity η_1, is, by Poiseuille's formula:

$$\eta_1 = \eta_0 \frac{\rho_1 t_1}{\rho_0 t_0}.$$

As has been mentioned, and will be discussed more fully below, the viscosity of all liquids decreases with rising temperature, and measurements are therefore carried out in a thermostat, *i.e.*, a bath of suitable liquid, the temperature of which is kept constant by a regulating device. The viscosity coefficients of a number of pure liquids are given in Table I, and those of a number of liquids of technical interest, which are not so well defined, in Table II.

TABLE I. *Viscosity Coefficients of Pure Liquids in Centipoises Temperature 20° Unless Otherwise Stated*

Water at 0°	1·7921	Carbon disulphide	0·367
,, ,, 10°	1·3077	Acetone	0·3225
,, ,, 20°	1·0050	Formic acid	1·782
,, ,, 50°	0·5494	Acetic ,,	1·219
,, ,, 100°	0·2838	Propionic acid	1·099
Ethyl alcohol	1·192	Benzene	0·649
Methyl ,,	0·591	Toluene	0·586
Chloroform	0·564	O-xylene	0·897
Carbon tetrachloride	0·969		

TABLE II. *Viscosity Coefficients of Technical Liquids in Centipoises Temperature 20° Unless Otherwise Stated*

100% Sulphuric acid	24·2	Shale oil	7·70
Olive oil	80·8	Spindle oil	92·0
Glycerin at 25°	735·0	Rumanian fuel oil at 25°	515·0
Castor oil at 25°	621·0		
Turpentine	1·46		
"Standard White" paraffin	2·375		

Viscosity and Temperature.—Two fairly typical examples of the variation of viscosity with temperature are given in fig. 6, in which the viscosity coefficients of water and of mercury are plotted against the temperatures (lower scale for water, upper for mercury). The viscosity decreases throughout the whole range, but the decrease per degree is much greater at low than at high temperature. The viscosity of water decreases by about 2·7% per degree between 0° and 10°, by about 2% per degree between 10° and 20°, etc., while the decrease is much more uniform for mercury.

No general law connecting viscosity with temperature has yet been found, although for any given liquid the variation can be represented with fair accuracy by one of a number of interpolation formulae.

Viscosity and Pressure.—The viscosity of all liquids so far examined, except water, increases with pressure and may attain enormous values when the pressure becomes very high. This has been demonstrated by Bridgman, who investigated over 40 liquids at pressures up to 12,000 atmospheres and at two temperatures,

30° and 75°. Earlier workers had examined a few liquids at pressures up to 3,000 atmospheres. Up to this limit the viscosity generally increases in approximately linear ratio with the pressure, but beyond it the increase becomes much more rapid. This is well shown in fig. 7, in which the relative viscosities (the viscosity at atmospheric pressure being taken as unity) of (A) ether and (B) carbon disulphide are plotted against the pressures: at 12,000 atmospheres the viscosity of ether is about 46 times, and that of carbon disulphide about 15 times that at atmospheric pressure. These are, however, liquids in which the effect of pressure is comparatively small; in many others the viscosity at the highest attainable pressures is many hundred and even thousand times as high as at atmospheric pressure.

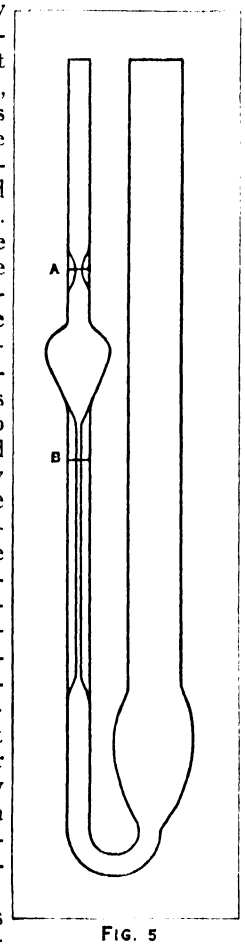


FIG. 5

As mentioned, Bridgman determined the viscosities at 30° and at 75°; at the same pressure the viscosity at the higher temperature is always smaller than at the lower. The liquid at the higher temperature, however, occupies a greater volume than at the lower, when the pressures are equal, and since it is very natural to assume that the change in viscosity caused by either temperature or pressure is merely a consequence of the accompanying change in volume, it is of great interest to compare the viscosities at equal volumes. The volumes corresponding to different pressures up to 12,000 atmospheres were determined by Bridgman in an earlier investigation; they are plotted in fig. 8 as abscissae and the viscosities at 30° and 75° corresponding to them as ordinates. The viscosity at 30° is always higher than that at 75° and at the same volume; in other words, the viscosity is not determined by the volume alone, as has been assumed in several theories. The point is of fundamental importance and still awaits explanation.

Water behaves anomalously, as it does in respect of other physical properties. At temperatures below about 30° the viscosity at first decreases with increasing pressure and shows a minimum at about 1,000 atmospheres, which is the more marked the lower the temperature. At temperatures above 30° water behaves like other liquids, *i.e.*, the viscosity increases with the pressure throughout the whole range.

Viscosity and Chemical Constitution.—Thomas Graham, the founder of colloid chemistry, who carried out a great number of viscosity measurements by Poiseuille's method, was the first to suggest that the viscosity of compounds of similar constitution might increase in a regular manner with the number of molecules or groups contained in them. Several investigations have been directed towards establishing such a connection, the best known of which was carried out by Thorpe and Rodger. They found that in any homologous series the viscosity increased with the molecular weight, the increase being fairly regular with the higher members, while the first two or three behaved anomalously—as they do in regard to other physical properties. Series like the alcohols and the fatty acids show considerable irregularities which are ascribed to association, *i.e.*, to their consisting, not of single molecules, but of complexes of such, which break up with rising temperature. There is other evidence of association, and the anomalies of water are ascribed to the same cause.

Viscosity of Solutions and Mixtures.—The investigations on both these have been extremely numerous. Solutions of all non-electrolytes and of electrolytes with certain well-known exceptions have viscosities higher than that of the solvent, the increase for equal increments of dissolved substance becoming higher at high concentrations. The exceptions are solutions of certain salts of potassium, ammonium, rubidium and caesium in water or alcohol, which, between certain limits of temperature and concentration, have viscosities lower than that of the solvent.

The viscosity of all solutions, like that of pure liquids, decreases with rising temperature; the effect is even more marked than in the latter, especially at high concentration. This is well shown in fig. 9, in which the viscosities of 40 and 60% cane sugar solutions are plotted against the temperature; the viscosity of the 60% solution at 0° is over 70 times, and that of the 40% solution about 15 times the respective values at 100°; for water this ratio is about 6·3.

It has so far been impossible to find the law connecting the viscosity of a solution with its concentration, and none of the empirical formulae which have been proposed fits more than a limited number of solutions. There are hardly any mixtures the viscosity of which is the mean calculated from the viscosities and percentages of the two components; if the viscosity of a mixture of chemically quite indifferent liquids is plotted against the percentage of one component, a slightly sagged curve (fig. 10) is the nearest approach to the straight line (dotted) which would represent the viscosity of the "ideal" mixture. It frequently happens, however, that the curve has a maximum (fig. 11) or a minimum (fig. 12); in other words, the viscosity of the mixture, at certain ratios of the components, is greater or smaller than the viscosity of either alone. The maximum or minimum may occur at the same concentration at all temperatures (fig. 11) or it may shift with changing temperature (fig. 12). Maxima and minima frequently occur at ratios, at which other physical constants, like the specific volume or the boiling point, also show extreme values; thus Poiseuille and Graham already observed, that the viscosity-maximum of the alcohol-water mixture occurred at the same ratio as the greatest contraction on mixing.

It has not so far been possible to formulate any molecular theory of the viscosity of liquid which accounts even qualitatively for the variations with temperature and pressure. The kinetic theory of gases, on the other hand, led to some very striking conclusions regarding the viscosity of gases, which were subsequently verified by experiment and must now be described briefly.

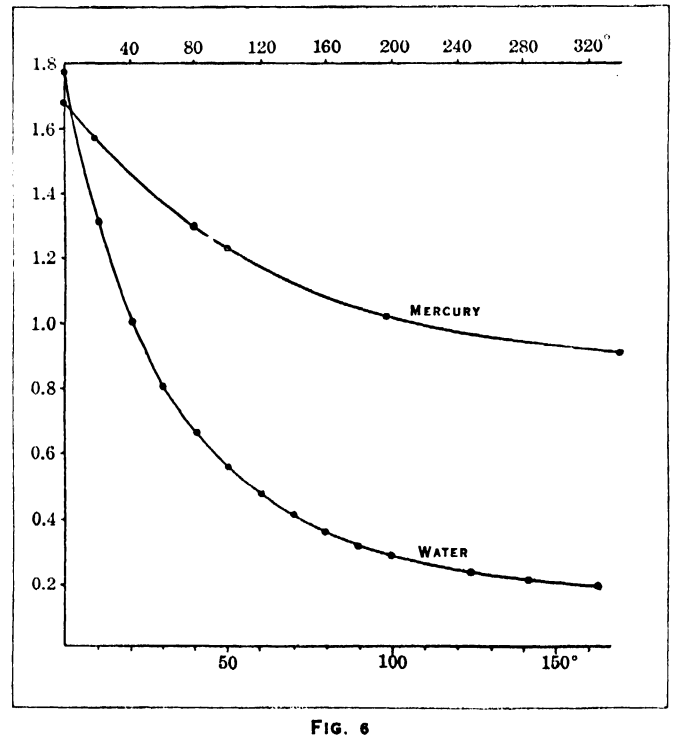

FIG. 6

The Viscosity of Gases.—A few years after the publication of Poiseuille's paper Thomas Graham investigated very carefully the flow of gases through capillaries. The times in which equal volumes of different gases passed through the same tubes under

the same pressure were different and were expressed as "transpiration coefficients," the time for oxygen being taken as unity. Graham found the same transpiration coefficients with different tubes, so that they represented a constant characteristic of the gas itself. Maxwell in developing the kinetic theory of gases deduced an expression from which it follows immediately that (1) the viscosity of a gas is independent of the pressure, and (2)

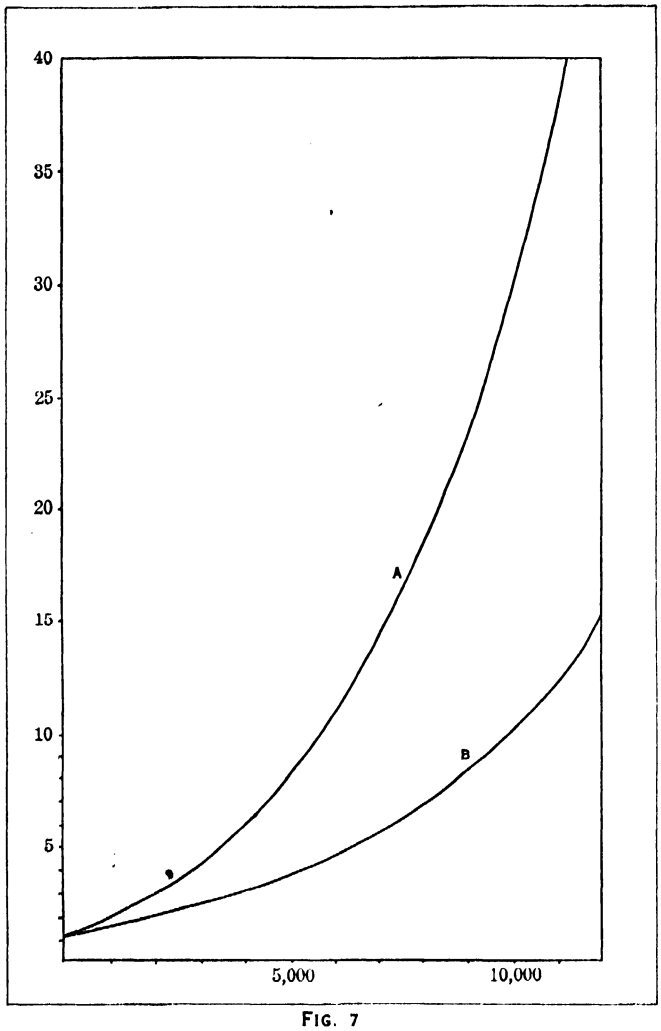

FIG. 7

it increases with rising temperature in linear ratio with the square root of the absolute temperature. (*See* KINETIC THEORY OF MATTER.)

The first of these very striking and unexpected conclusions was verified experimentally by O. E. Meyer and subsequently with improved apparatus by Maxwell himself. The method used was one which had been applied to liquids before: a set of three circular discs A (fig. 13) suspended from a fine wire was made to oscillate round its axis between four fixed discs A′; the viscosity of the air damps the oscillations and can be deduced from the decrease in their amplitudes. The viscosity of air was in this way found to be constant between pressures of 760 mm. of mercury (normal barometric pressure) and 1 millimetre. There are considerable deviations from this law at high pressures, and at very low pressures, when the mean free path of the molecules becomes comparable to the dimensions of the vessel, the viscosity diminishes very considerably. This property has been utilized in the construction of gauges for extremely low pressures. (*See* VACUUM.)

Meyer also deduced from the kinetic theory that the flow of gases through capillaries followed Poiseuille's law, and calculated from Graham's "transpiration coefficients" and the dimensions of his tubes the viscosity coefficients of a number of gases. The capillary method has also been used very generally by later investigators. The viscosity coefficients of a few gases at 0° are given below in centipoises; it will be noticed that the viscosity coefficient of air at that temperature is almost exactly $\frac{1}{100}$ of that of water at 0°.

TABLE III. *Viscosity Coefficients of Gases in Centipoises Temperature 0°*

Atmospheric air	0·01719	Carbon dioxide	0·01382
Oxygen	0·01973	Sulphur dioxide	0·01168
Hydrogen	0·00849	Ammonia	0·00957
Carbon monoxide	0·01665		

It has also been shown that Stokes's formula applies to the fall of spheres in gases as well as in liquids, provided the spheres are not small compared with the mean free path. It is a matter of common experience that very finely divided matter stays suspended in air for a considerable time, and Stokes's formula can be used to calculate the size of particles of a given material, *e.g.*, droplets of water, which will sink at a given rate. If this is to be say 1 cm. per hour, the diameter of the globule must not exceed $1{\cdot}38\mu$ ($1\ \mu = \frac{1}{1000}$ mm.).

The striking prediction that the viscosity of gases, unlike that of liquids, increases with rising temperature, has also been verified experimentally. The viscosity is not, however, proportional to the square root of the absolute temperature, as theory requires, but increases much more rapidly. The discrepancy has been

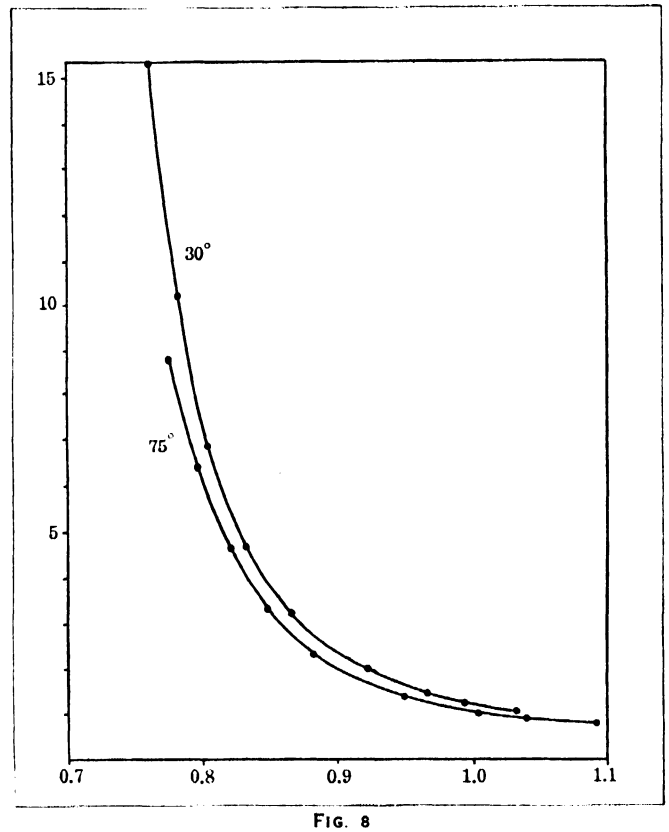

FIG. 8

explained by Sutherland, who found the actual law of the variation with absolute temperature to be

$$\eta = A\frac{\sqrt{T}}{1+C/T}$$

where C is a constant for each gas, known as Sutherland's constant.

The Viscosity of Solids.—The first physicist to put forward and to define the concept of viscosity in solids, more especially in "highly elastic solids within the limits of high elasticity" was Sir William Thomson (afterwards Lord Kelvin); he did so in a paper published in the *Proceedings* of the Royal Society in 1865 and afterwards included in the article "Elasticity" in the 4th edition of the *Encyclopædia Britannica*. The concept is a difficult one,

but the difficulty is not so much that of defining viscosity or viscous flow as that of defining a solid. Stokes, *e.g.*, suggested that "there seems no line of demarcation between a solid and a viscous fluid"; Maxwell, on the other hand, considered any body which exhibited flow at all stresses as a liquid, whereas bodies which did not flow until a certain minimum stress had been exceeded, were plastic solids. It has become quite usual to describe, in accordance with

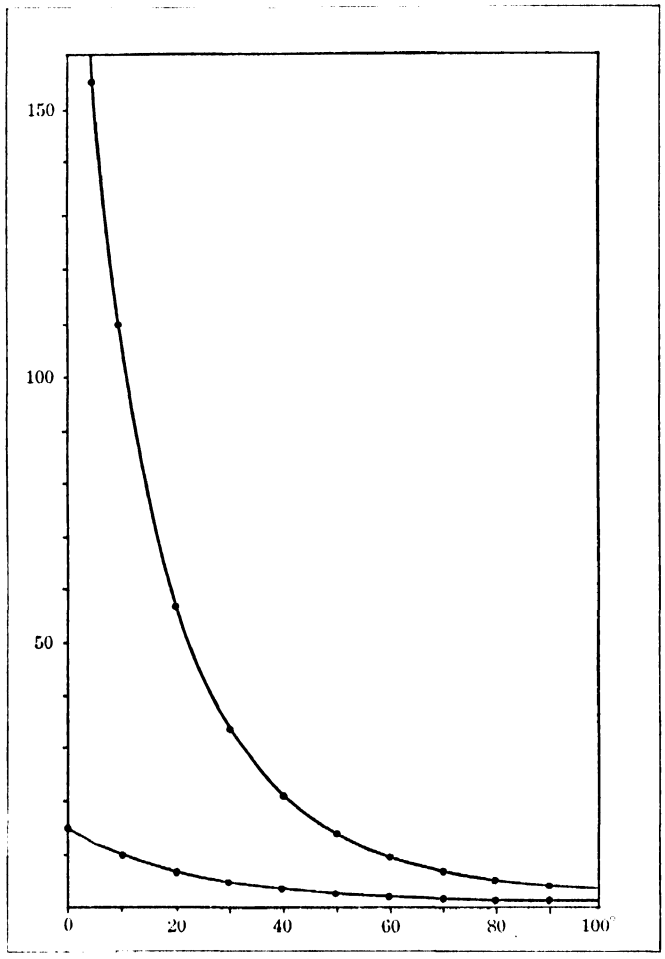

FIG. 9

Maxwell's view, glass as a "supercooled liquid" (although, unlike liquids, it is capable of transverse vibrations) and to confine the term solid to crystalline bodies or, more strictly still, to single crystals.

If one follows Stokes rather than Maxwell it is easy to find such transitions, viz., bodies which at ordinary temperature maintain their shape and vibrate when touched with a vibrating tuning fork, but under continued low stress flow. Pitch is representative of this class and has been much investigated; it has been shown that at ordinary temperature, when it is "solid," it can be forced through a capillary and exhibits purely viscous flow in accordance with Poiseuille's law. At 13·3° the coefficient of viscosity is about 5,000 million poises, and at 99·9° about 120 poises; the decrease in viscosity is quite continuous.

The viscosity coefficient of substances like pitch, which at low temperatures keep their shape, can be determined by methods not applicable to liquids; it can, for example, be deduced from the rate at which a cylinder, to one end of which a constant torque is applied, is twisted. The method was used by Trouton and Andrews, who found that even in pitch there were some elastic effects, the cylinder untwisting to a small extent when the torque was removed. Thomson studied the decrement of the amplitude of torsional oscillations performed by wires from which heavy masses were suspended, with a view to finding whether the damping could be completely accounted for by an internal resistance of the nature of viscosity, but arrived at a negative result.

The difficulty encountered in studying viscous flow in solids is, in fact, that of separating it from other types of deformation, which may precede or accompany it. The most successful pro-

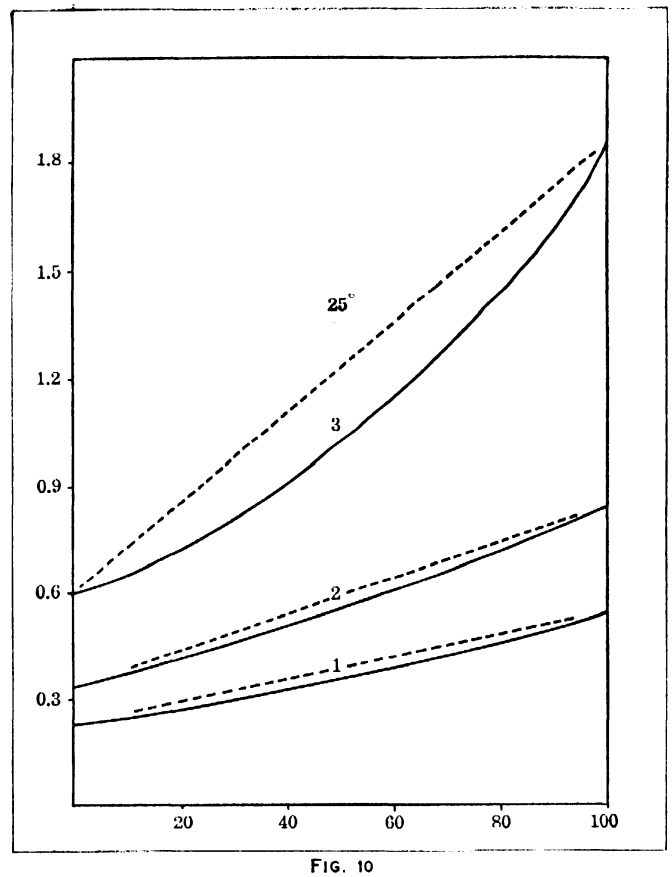

FIG. 10

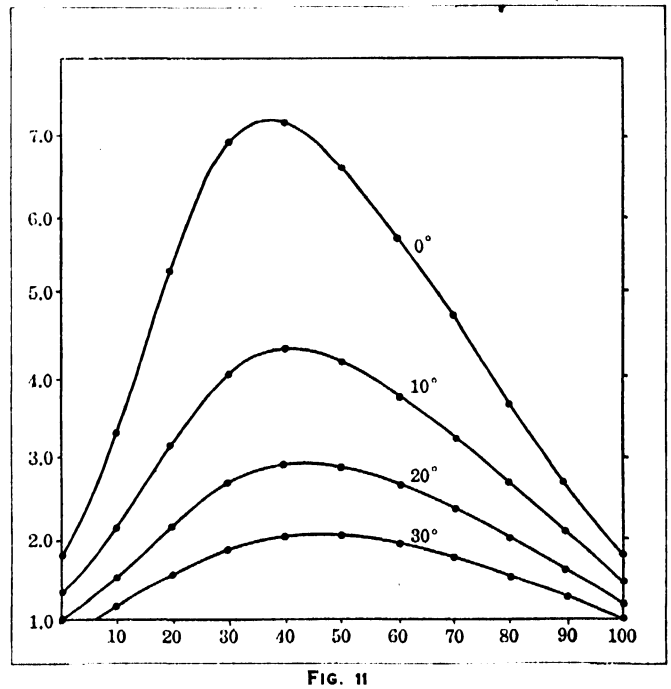
cedure for doing so is that adopted by Andrade, who measured the rate of elongation of metal wires stretched by constant stress. If a wire is stretched, as is often done, by a constant load, the



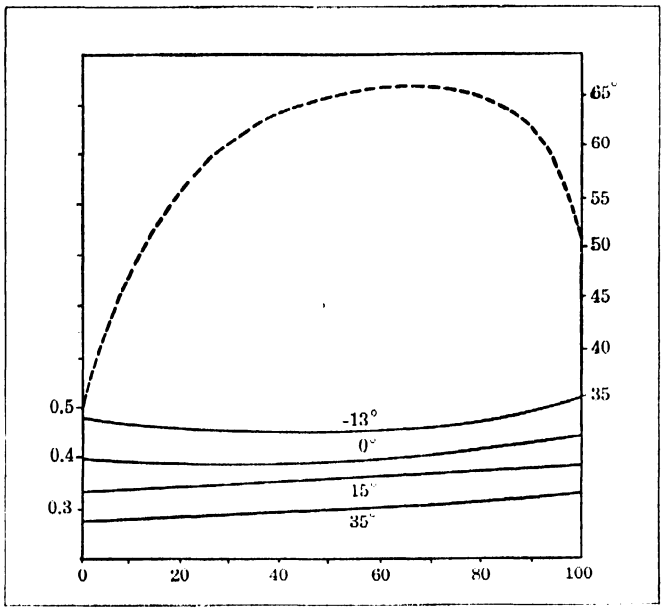


FIG. 11

stress, *i.e.*, the load per unit area, keeps increasing, as the cross-section becomes smaller when the wire becomes longer. Andrade decreased the load in the same ratio in which the cross-section was reduced by giving the weight, which stretched the wire, a

suitable profile and allowing it to sink into a liquid, as the wire became longer. He found in this way that the elongation could be divided into three parts: an immediate extension on loading, an initial flow which decreases with time and is therefore not

FROM FAUET, IN "ZEITSCHRIFT FUR PHYSIKALISCHE CHEMIE" (AKADEMISCHE VERLAGSGESELLSCHAFT, LEIPZIG)

FIG. 12

viscous, and then a constant flow, during which the rate of elongation per unit length is constant up to the breaking point; this is the purely viscous flow. A wide region of viscous flow was found with lead, copper and fuse (lead-tin alloy) wire at ordinary temperature. Other metals were found to behave like lead when a suitable temperature was chosen: a wire of frozen mercury at −78° gave time-extension curves intermediate between those of lead at 160° and 17° while iron wire at 444° behaved like lead at 16°. The higher the temperature the more does viscous flow predominate. No viscosity coefficients have been deduced from the experiments just described.

VISCOUNT, the title of the fourth rank of the European nobility. In the British peerage it intervenes between the dignities of earl and baron. The title is now purely one of honour, having long been dissociated from any special office or functions.

In the Carolingian epoch the *vice-comites*, or *missi comitis*, were the deputies or vicars of the counts, whose official powers they exercised by delegation, and from these the viscounts of the feudal period were undoubtedly derived. Soon after the counts became hereditary the same happened in the case of their lieutenants; *e.g.*, in Narbonne, Nîmes and Alby the viscounts had, according to A. Molinier, acquired hereditary rights as early as the beginning of the 10th century. Viscountcies thus developed into actual fiefs. Viscounts, however, continued for some time to have no more than the status of lieutenants, either calling themselves simply *vice-comites*, or adding to this title the name of the countship from which they derived their powers. It was not till the 12th century that the universal tendency to territorialize the feudal dominions affected the viscountcies with the rest, and that the viscounts began to take the name of the most important of their domains. Thus the viscounts of Poitiers called themselves viscounts of Thouars, and those of Toulouse viscounts of Bruniquel and Montelar. From this time the significance of the title was extremely various. Some viscounts, notably in the duchy of Aquitaine and the county of Toulouse, of which the size made an effective centralized Government impossible, were great barons, whose authority extended over whole provinces, and who disputed for power with counts and dukes. Elsewhere, on the other hand, *e.g.*, in the Ile de France, Champagne, and a great part of Burgundy, the *vicomtes* continued to be half feudatories, half officials of the counts, with the same functions and rank in the feudal hierarchy as the chatelains; their powers were jealously limited and, with the organization of the system of *prévôts* and *baillis* in the 12th century, practically disappeared. In the royal domains especially, these petty feudatories could not maintain themselves against the growing power of the Crown, and they were early assimilated to the *prévôts*.

In Normandy *vicomtes* appeared at a very early date as deputies of the counts (afterwards dukes) of the Normans. When local Norman counts began in the 11th century, some of them had *vicomtes* under them, but the normal *vicomte* was still a deputy of the duke, and Henry I. largely replaced the hereditary holders of the *vicomtés* by officials. "By the time of the Conqueror the judicial functions of the viscount were fully recognized, and extended over the greater part of Normandy." Eventually almost the whole of Normandy was divided into administrative viscountcies or bailiwicks by the end of the 12th century. When the Normans conquered England, they applied the term *viscounte* or *vicecomes* to the sheriffs of the English system, whose office, however, was quite distinct and was hardly affected by the Conquest.

Nearly four centuries later "viscount" was introduced as a peerage style into England, when its king was once more lord of Normandy. John, Lord Beaumont, K.G., who had been created count of Boulogne in 1436, was made Viscount Beaumont, Feb. 12, 1440, and granted precedence over all barons, which was doubtless the reason for his creation. The oldest viscountcy now on the roll is that of Hereford, created in 1550; but the Irish viscountcy of Gormanston is as old as 1478. *See* FORMS OF ADDRESS.

VISHNU [Sanskr. the "active one"], in the Indian *Rig-Veda* a minor deity, who takes three strides, *vi-kram*, the last and highest beyond mortal ken; these probably denote the three divisions of the universe. Closely allied with Indra in his fight with Vritra, the drought-dragon, and against the Dāsas, the dark aborigines, Vishnu in the Epic mythology developed into the Preserver god, one of the Hindu triad with Brahma, the creator; and Siva, the destroyer; and as such he has saved mankind in ten incarnations. His special devotees, the Vaishnavas, have evolved numerous sects.

VISION or **SIGHT,** the function, in physiology, of the organ known as the eye (*q.v.*). The sense of vision is excited by the influence of light on the retina, the special terminal organ connected with the optic nerve. By excitation of the retina, a change is induced in the optic nerve fibres, and is conveyed by these to the brain, the result being a luminous perception, or what we call a sensation of light or colour. If light were to act uniformly over the retina, there would be no image of the source of the light formed on that structure, and consequently there would be only a general consciousness of light, without reference to any particular object. One of the first conditions, therefore, of vision for useful purposes is the formation of an image on the retina. To effect this, just as in a photographic camera, refractive structures must be placed in front of the retina which will so bend luminous rays as to bring them to a focus on the retina, and thus produce an image. Throughout the animal kingdom various arrangements are found for this purpose; but they may

be all referred to three types, namely—(1) eye-specks or eye-dots, met with in Medusae, Annelidae, etc.; (2) the compound eye, as found in insects and crustaceans; and (3) the simple eye, common to all vertebrates. The *eye-specks* may be regarded simply as expansions of optic nerve filaments, covered by a transparent membrane, but having no refractive media, so that the creature would have the consciousness of light only, or a simple luminous impression, by which it might distinguish light from darkness. The *compound eye* consists essentially of a series of transparent cone-like bodies, arranged in a radiate manner against the inner surface of the cornea, with which their bases are united, while their apices are connected with the ends of the optic filaments. As each cone is separated from its neighbours, it admits only a ray of light parallel with its axis, and its apex represents only a portion of the image, which must be made up, like a mosaic-work, of as many parts as there are cones in the eye. The size of the visual field will depend on the size of the segment of the sphere forming its surface.

The eyes of many insects have a field of about half a sphere, so that the creature will see objects before and behind it as well as those at the side. On the other hand, in many the eyes have scarcely any convexity, so that they must have a narrow field of vision.

For numerous anatomical details, and various diseases connected with the eye, *see* EYE; the pathological aspects of vision itself are treated at the conclusion of this article.

1. PHYSICAL CAUSES OF VISION

A luminous sensation may be excited by various modes of irritation of the retina or of the optic nerve. Pressure, cutting or electrical shocks may act as stimuli, but the normal excitation is the influence of light on the retina. From a physical point of view, light is a mode of movement occurring in a medium, termed the aether, which pervades all space; but the physiologist studies the operation of these movements on the sentient organism as resulting in consciousness of the particular kind which we term a luminous impression. Outside of the body, such movements have been studied with great accuracy; but the physiological effects depend upon such complex conditions as to make it impossible to state them in the same precise way. Thus, when we look at the spectrum, we are conscious of the sensations of red and violet, referable to its two extremities: the physicist states that red is produced by 392 billions of impulses on the retina per second, and that violet corresponds to 757 billions per second; but he has arrived at this information by inductive reasoning from facts which have not at present any physiological explanation. Below the red and above the violet ends of the spectrum there are vibrations which do not excite luminous sensations. In the first case, below the red, the effect is to raise the temperature; and above the violet the result is to cause chemical activity in the substance by which the radiation is absorbed. Thus the method of dispersion of light, as is followed in passing a ray through a prism, enables us to recognize these general facts: (1) rays below the red excite thermal impressions; (2) from the lower red up to the middle of the violet, the thermal rays become gradually weaker until they have no effect; (3) from the lower red to the extreme violet, they cause luminous impressions, which reach their greatest intensity in the yellow; and (4) from about the end of the yellow to far beyond the extreme violet, the rays have gradually a less and less luminous effect, but they have the power of exciting such chemical changes as are produced in photography. In general terms, therefore, the lower end of the spectrum may be called thermal, the middle luminous, and the upper actinic or chemical; but the three merge into and overlap one another.' It may be observed that the number of vibrations in the extreme violet is not double that of the low red, so that the sensibility of the eye to vibrations of light does not range through an octave. The ultra-violet rays may act on the retina in certain conditions, as when they are reflected by a solution of sulphate of quinine, constituting the phenomenon of fluorescence. Far above the violet are the Röntgen radiations, γ rays, etc.

2. OPTICAL ARRANGEMENTS OF THE EYE

1. **General.**—When light traverses any homogeneous transparent medium, such as the air, it passes on in a straight course with a certain velocity; but if it meet with any other transparent body of a different density, part of it is reflected or returned to the first medium, whilst the remainder is propagated through the second medium in a different direction and with a different velocity. Thus we may account for the phenomena of reflection of light and of refraction (*q.v.*).

Before a ray of light can reach the retina, it must pass through a number of transparent and refractive surfaces. The eye is a nearly spherical organ, formed of transparent parts situated behind each other, and surrounded by various membranous structures, the anterior part of which is also transparent. The transparent parts are—(1) the *cornea;* (2) the *aqueous humour,* found in the anterior chamber of the eye; (3) the *crystalline* lens, formed by a transparent convex body, the anterior surface of which is less convex than the posterior; and (4) the *vitreous humour,* filling the posterior chamber of the eye. The ray must therefore traverse the cornea, aqueous humour, lens and vitreous humour. As the two surfaces of the cornea are parallel, the rays practically suffer no deviation in passing through that structure, but they are bent during their transmission through the other media.

2. **The Formation of an Image on the Retina.**—This may be well illustrated with the aid of a photographic camera. If properly focused, an inverted image will be seen on the glass plate at the back of the camera. It may also be observed by bringing the eyeball of a rabbit near a candle flame. The action of a lens in forming an inverted image is illustrated by fig. 1, where the pencil of rays proceeding from *a* is brought to a focus at *a'*, and those from *b* at *b';* consequently the image of *ab* is inverted as at *b'a'*. The three characteristic features of the retinal image are: (1) it is reversed; (2) it is sharp and well defined if it be accurately focused on the retina; and (3) its size depends on the visual angle. If we look at a distant object, say a star, the rays reaching the eye are parallel, and in passing through the refractive media they are focused at the posterior focal point—that is, on the retina. A line from the luminous point on the retina passing through the nodal point is called the *visual line.*

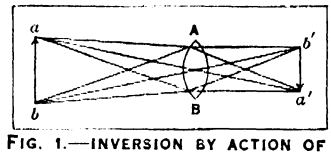

FIG. 1.—INVERSION BY ACTION OF A LENS

If the luminous object be not nearer than, say, 60 yd. the image is still brought to a focus on the retina without any effort on the part of the eye. Within this distance, supposing the condition of the eye to be the same as in looking at a star, the image would be formed somewhat behind the posterior focal point, and the effect would be an indistinct impression on the retina. To obviate this, for near distances, accommodation, so as to adapt the eye, is effected by a mechanism to be afterwards described.

When rays, reflected from an object or coming from a luminous point, are not brought to an accurate focus on the retina, the image is not distinct in consequence of the formation of *circles of diffusion,* the production of which will be rendered evident by fig. 2. From the point A luminous rays enter the eye in the form of a cone, the kind of which will depend on the pupil. Thus it may be circular, or oval, or even triangular. If the pencil is focused in front of the retina, as at *d,* or behind it as at *f,* or, in other words, if the retina, in place of being at F, be in the positions G or H, there will be a luminous circle or a luminous triangular space, and many elements of the retina will be affected. The size of these diffusion circles depends on the distance from the retina of the point where the rays are focused: the greater the distance, the more extended will be the diffusion circle. Its size will also be affected by the greater or less diameter of the pupil. Circles of diffusion may be

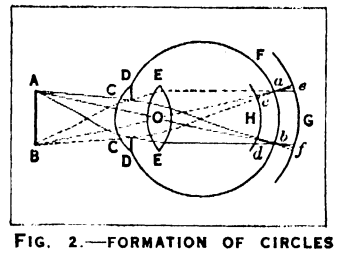

FIG. 2.—FORMATION OF CIRCLES OF DIFFUSION

studied by the following experiment, called the experiment of Scheiner, fig. 3:

Let C be a lens, and DEF be screens placed behind it. Hold in front of the lens a card perforated by two holes A and B, and allow rays from a luminous point *a* to pass through these holes. The point *o* on the screen E will be the focus of the rays emanating from *a;* if *a* were removed farther from the lens, the focus would be on F, and if it were brought near to C, the focus would then be on D. The screens F and D show two images on the point *a*. If, then, we close the upper opening in AB, the *upper* image *m* on F and the *lower* image *n* on D disappear. Suppose now that the retina be substituted for the screens D and F, the contrary will take place, in consequence of the reversal of the retinal image. If the eye be placed at *o*, only one image will be seen; but if it be placed either in the plane of F or D, then two images will be seen, as at *mm*, or *nn;* consequently, in either of these planes there will be circles of diffusion and indistinctness, and only in the plane E will there be sharp definition of the image.

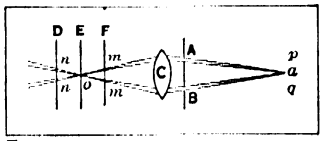

FIG. 3.—DIAGRAM ILLUSTRATING THE EXPERIMENT OF SCHEINER

Owing to the optical conditions and defects of the eye (*vide infra*) a mathematically punctate image is never formed upon the retina, even in a normal eye. To understand the formation of an image on the retina, suppose a line drawn from each of its two extremities to the nodal point and continued onwards to the retina, as in fig. 4, where the visual angle is *x*. It is evident that its size will depend on the size of the object and the distance of the object from the eye. Thus, also, objects of different sizes, *c*, *d*, *e* in fig. 4, may be included in the same visual angle, as they are at different distances from the eye. The size of the retinal image may be calculated if we know the size of the object, its distance from the nodal point *o*, and the distance of the nodal point from the posterior focus. The smallest visual angle in which two distinct points may be observed is approximately 60 seconds; below this, the two sensations fuse into one; and the size of the retinal image corresponding to this angle is ·004 mm., about the diameter of a single retinal rod or cone. The images of two luminous points, *e.g.*, stars, must therefore be separated by the diameter of one cone, *i.e.*, the two cones stimulated must be separated by one unstimulated cone. A very minute image, if thrown on a single retinal element, is sufficient to excite it if the illumination is sufficiently intense.

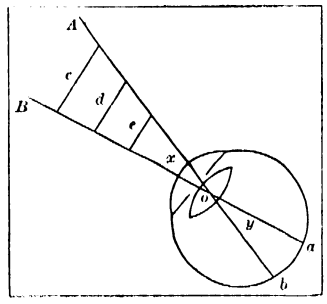

FIG. 4.—THE VISUAL ANGLE

3. **The Optical Defects of the Eye.**—As an optical instrument; the eye is defective. These defects are chiefly of two kinds—(1) those due to the curvature of the refractive surfaces, and (2) those due to the dispersion of light by the refractive media.

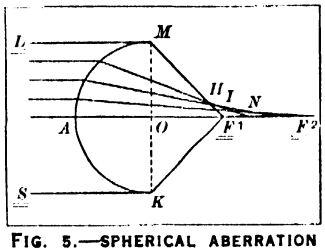

FIG. 5.—SPHERICAL ABERRATION

(*a*) *Aberration of Sphericity.*—Suppose, as in fig. 5, M A K to be a refractive surface on which parallel rays from L to S impinge, it will be seen that those rays passing near the circumference are brought to a focus at F^1, and those passing near the centre at F^2—intermediate rays being focused at N. Thus on the portion of the axis between F^1 and F^2 there will be a series of focal points, and the effect will be a blurred and bent image. In the eye this defect is to a large extent corrected by the following arrangements: (1) the iris cuts off the outer and more strongly refracted rays; (2) the curvature of the cornea is flatter at the periphery, and consequently those farthest from the axis are least deviated; (3) the anterior and posterior curvatures of the lens are such that the one corrects, to a certain extent, the action of the other; and (4) the structure of the lens is such that its power of refraction diminishes from the centre to the circumference, and consequently the rays farthest from the axis are less refracted.

(*b*) *Astigmatism.*—Another common defect of the eye is due to different meridians having different degrees of curvature. This defect is known as *astigmatism*. It may be thus detected.

In the cornea the vertical meridian has generally a shorter radius of curvature, and is consequently more refractive than the horizontal. The meridians of the lens may also vary; but, as a rule, the asymmetry of the cornea is greater than that of the lens. The optical explanation of the defect will be understood with the aid of fig. 6. Thus, suppose the vertical meridian C A D to be more strongly curved than the horizontal F A E, the rays which fall on C A D will be brought to a focus, G, and those falling on F A E at B. If we divide the pencil of rays at successive points, G, H, I, K, B, by a section perpendicular to A B, the various forms it would present at these points are seen in the figures underneath, so that if the eye were placed at G, it would see a horizontal line *a a'*; if at H, an ellipse with the long axis *a a'* parallel to A B; if at I, a circle; if at K, an ellipse, with the long axis, *b c*, at right angles to A B; and if at B, a vertical line *b c*. The degree of astigmatism is ascertained by measuring the difference of refraction in the two chief meridians; and the defect is corrected by the use of cylindrical glasses, the curvature of which, added to that of the minimum meridian, makes its focal length equal to that of the maximum meridian.

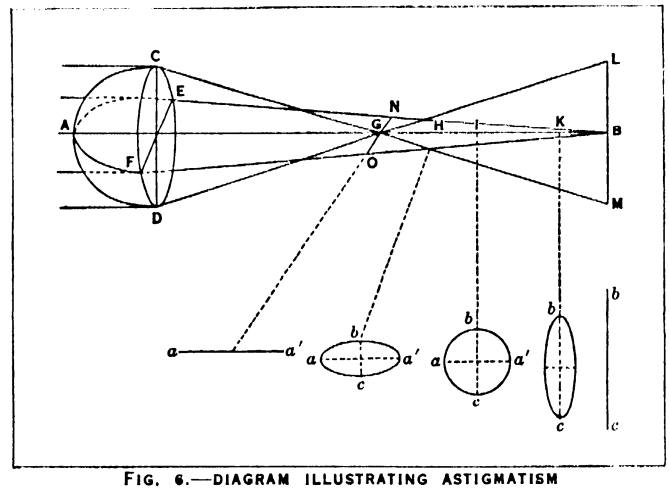

FIG. 6.—DIAGRAM ILLUSTRATING ASTIGMATISM

(*c*) *Chromatic Aberration.*—When a ray of white light traverses a lens, the different rays composing it, being unequally refrangible, are dispersed: the violet rays (*see* fig. 7), the most refrangible, are brought to a focus at *e*, and the red rays, less refrangible, at *d*. If a screen were placed at *e*, a series of concentric coloured circles would be formed, the central being of a violet, and the circumference of a red colour. The reverse effect would be produced if the screen were placed at *d*. Imagine the retina in place of the screen in the two positions, the sensational effects would be those just mentioned. Under ordinary circumstances, the error is not observed, as for vision at near distances the interval between the focal point of the red and violet rays is very small. If, however, we look at a candle flame through a bit of cobalt blue glass, which transmits only the red and blue rays, the flame may appear violet surrounded by blue, or blue surrounded by violet, according as we have accommodated the eye for different distances. Red surfaces appear nearer than violet surfaces situated in the same plane.

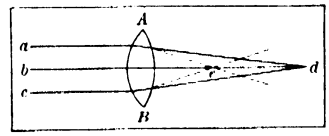

FIG. 7.—DIAGRAM ILLUSTRATING THE DISPERSION OF LIGHT BY A LENS

(*d*) *Diffraction.*—The rays are best at the edge of the pupil, breaking up the light into a series of concentric spectra. This

contributes to the imperfection of the image. The effect is greatest with a small pupil, but is practically negligible with a pupil of 3 mm. diameter or more. Chromatic aberration and diffraction tend to counteract each other.

(*e*) *Defects Due to Opacities, etc., in the Transparent Media.*— When small opaque particles exist in the transparent media, they may cast their shadow on the retina so as to give rise to images which are projected outwards by the mind into space, and thus appear to exist outside of the body. Such phenomena are termed entoptic. They may be of two kinds: (1) *extra-retinal*, that is, due to opaque or semi-transparent bodies in any of the refractive structures anterior to the retina, and presenting the appearance of drops, striae, lines, twisted bodies, forms of grotesque shape, or minute black dots dancing before the eye; and (2) *intra-retinal*, due to opacities, etc., in the layers of the retina, in front of the rods and cones. The intra-retinal may be produced in a normal eye in various ways. (1) Throw a strong beam of light on the edge of the sclerotic, and a curious branched figure will be seen, which is an image of the retinal vessels. The construction of these images, usually called *Purkinje's figures*, will be understood from fig. 8. Thus, in the figure to the left, the rays passing through the sclerotic at *b″*, in the direction *b″ c*, will throw a shadow of a vessel at *c* on the retina at *b′*, and this will appear as a dark line at B. If the light move from *b″* to *a″*, the retinal shadow will move from *b′* to *a′*, and the line in the field of vision will pass from B to A. It may be shown that the distance *c b′* corresponds to the distance of the retinal vessels from the layer of rods and cones. If the light enter the cornea, as in the figure to the right, and if the light be moved, the image will be displaced in the same direction as the light, if the movement does not extend beyond the middle of the cornea, but in the opposite direction to the light when the latter is moved up and down. Thus, if *a* be moved to *a′*, *d* will be moved to *d′*, the shadow on the retina from *c* to *c′*, and the image *b* to *b′*. If, on the other hand, *a* be moved above the plane of the paper, *d* will move below, consequently *c* will move above, and *b′* will appear to sink. (2) The retinal vessels may also be seen by looking at a strong light through a minute aperture, in front of which a rapid to-and-fro movement is made. Such experiments prove that the sensitive part of the retina is its deepest and most external layer (the rod and cone layer).

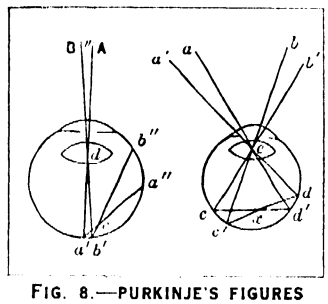

FIG. 8.—PURKINJE'S FIGURES

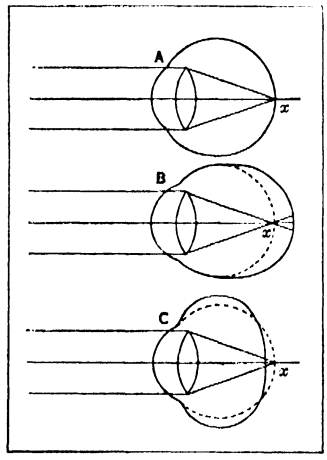

FIG. 9.—A. EMMETROPIC OR NORMAL EYE; B. MYOPIC OR SHORT-SIGHTED EYE; C. HYPERMETROPIC OR LONG-SIGHTED EYE

4. **Accommodation, or the Mechanism of Adjustment for Different Distances.**— When a camera is placed in front of an object, it is necessary to focus accurately in order to obtain a clear and distinct image on the sensitive plate. This may be done by moving either the lens or the sensitive plate backwards or forwards so as to have the posterior focal point of the lens corresponding with the sensitive plate. For similar reasons, a mechanism of adjustment, or accommodation for different distances, is necessary in the human eye. In the normal eye, any number of parallel rays, coming from a great distance, are focused on the retina. Such an eye is termed *emmetropic* (fig. 9). Another form of eye (B) may be such that parallel rays are brought to a focus *in front of* the retina. This form of eye is *myopic* or short-sighted, inasmuch as, for distinct vision, the object must be brought nearer to the eye. A third form is seen in C, where the focal point, for ordinary distances, is *behind* the retina, and consequently the rays must be made more convergent by accommodation. This kind of eye is called *hypermetropic*, or far-sighted. For ordinary distances, at which objects must be seen distinctly in everyday life, the fault of the myopic eye may be corrected by the use of concave and of the hypermetropic by convex glasses. In the first case, the concave glass will move the posterior focal point a little farther back, and in the second the convex glass will bring it farther forward; in both cases, however, the glasses may be so adjusted, both as regards refractive index and radius of curvature, as to bring the rays to a focus on the retina, and consequently secure distinct vision.

From any point 65 metres distant, rays may be regarded as almost parallel, and the point will be seen by the emmetropic eye without any effort of accommodation. This point, either at this distance or in infinity, is called the *punctum remotum*, or the most distant point seen without accommodation. In the myopic eye it is much nearer, and for the hypermetropic there is really no such point, and accommodation is always necessary. If an object were brought too close to the eye for the refractive media to focus it on the retina, such circles of diffusion would be formed as to cause indistinctness of vision, unless the eye possessed some power of adapting itself to different distances. That the eye has some such power of accommodation is proved by the fact that, if we attempt to look through the meshes of a net at a distant object, we cannot see both the meshes and the object with equal distinctness at the same time. Again, if we look continuously at very near objects, the eye speedily becomes fatigued. Beyond a distance of 65 metres, no accommodation is necessary; but within it, the condition of the eye must be adapted to the diminished distance until we reach a point near the eye which may be regarded as the limit of clear vision for near objects. This point, called the *punctum proximum*, varies according to the age of the individual. The range of accommodation is thus the distance between the *punctum remotum* and the *punctum proximum*.

The mechanism of accommodation has been much disputed, but there can be no doubt it is chiefly effected by a change in the curvature of the anterior surface of the crystalline lens. If we hold a lighted candle in front and a little to the side of an eye to be examined, three reflections may be seen in the eye, as represented in fig. 10. The first, *a*, is erect, large and bright, from the anterior surface of the cornea; the second, *b*, also erect, but dim, from the anterior surface of the crystalline lens; and the third, *c*, inverted, and very dim, from the posterior surface of the lens, or perhaps the concave surface of the vitreous humour to which the convex surface of the lens is adapted. Suppose the three images to be in the position shown in the figure for distant vision, it will be found that the middle image *b* moves towards *a*, on looking at a *near* object. The change is due to an alteration of the curvature of the lens, as shown in fig. 11. The changes occurring during accommodation are: (1) the curvature of the anterior surface of the crystalline lens increases, the radius of curvature changing from 10 mm. to a minimum of 6 mm., and (2) the pupil contracts. An explanation of the increased curvature of the anterior surface of the lens during accommodation has been thus given by H. von Helmholtz. In the normal condition, that is, for the emmetropic eye, the crystalline lens is flattened anteriorly by the pressure of the anterior layer of the capsule; during accommodation, the radiating fibres of the ciliary muscles pull the ciliary processes forward, thus relieving the tension of the anterior layer of the capsule, and the lens at once bulges forward by its elasticity.

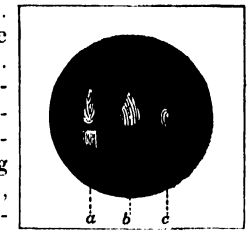

FIG. 10.—REFLECTED IMAGES IN THE EYE

By this mechanism the radius of curvature of the anterior surface of the lens, as the eye accommodates from the far to the near point, may shorten from 10 mm. to 6 mm. The ciliary muscle, however, contains two sets of fibres, the outer, longi-

tudinal or meridional, which run from before backwards, and the inner, circular or equatorial (Müller's muscle). Direct observation on the eye of an animal immediately after death shows that stimulation of the ciliary nerves actually causes a forward movement of the ciliary processes, and there can be little doubt that the explanation above given applies to man.

There is still some difficulty in explaining the action of the equatorial (circular) fibres. Some have found that the increased

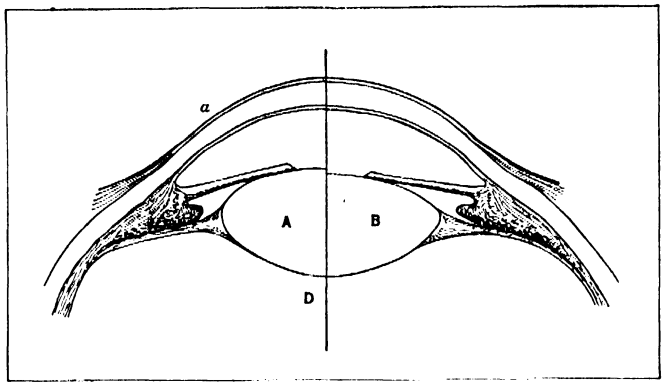

FIG. 11.—MECHANISM OF ACCOMMODATION

convexity of the anterior surface of the lens takes place only in the central portions of the lens, and that the circumferential part of the lens is actually flattened, presumably by the contraction of the equatorial fibres. Seeing, however, that the central part of the lens is the portion used in vision, as the pupil contracts during accommodation, a flattening of the margins of the lens can have no optical effect. During accommodation the pupil contracts, and the pupillary edge of the iris, thinned out, spreads over the anterior surface of the capsule of the lens, which it actually touches, and this part of the iris, along with the more convex central part of the lens, bulges into the anterior chamber, and must thus displace some of the aqueous humour. To make room for this, however, the circumferential part of the iris, related to the ligamentum pectinatum, moves backwards very slightly, while the flattening of the circumferential part of the lens facilitates this movement.

Helmholtz succeeded in measuring with accuracy the sizes of the reflected images by means of an instrument termed an *ophthalmometer,* the construction of which is based on the following optical principles:

5. **Absorption and Reflection of Luminous Rays from the Eye.**—When light enters the eye, it is partly absorbed by the black pigment of the retina and choroid and partly reflected. The reflected rays are returned through the pupil, not only following the same direction as the rays entering the eye, but uniting to form an image at the same point in space as the luminous object. The pupil of an eye appears black to an observer, because the eye of the observer does not receive any of these reflected rays. If, however, we illuminate the retina by a mirror held close to the eye the retina can be seen through a hole in the mirror. This is the *principle* of the ophthalmoscope originally invented by Babbage in 1848, and re-discovered by Helmholtz in 1851. Eyes deficient in pigment, as in albinos, appear luminous, reflecting light of a red or pink colour; but if we place in front of such an eye a card perforated by a round hole of the diameter of the pupil, the hole will appear quite dark, like the pupil of an ordinary eye. In many animals a portion of the fundus of the eyeball has a special reflecting membrane, which presents an iridescent appearance. This is called a *tapetum.* It probably renders the eye more sensitive to light of feeble intensity.

6. **Functions of the Iris.**—The iris constitutes a diaphragm which regulates the amount of light entering the eyeball. The aperture in the centre, the *pupil,* may be dilated by contraction of a system of radiating fibres of involuntary muscle, or contracted by the action of a circular system of fibres, forming a sphincter, at the margin of the pupil. The radiating fibres are controlled by the sympathetic, while those of the circular set are excited by the third cranial nerve. The variations in diameter of the pupil are determined by the greater or less intensity of the light acting on the retina. A strong light causes contraction of the pupil; with light of less intensity, the pupil will dilate. In the human being, a strong light acting on one eye will cause contraction of the pupil, not only in the eye affected, but in the other eye. These facts indicate that the phenomenon is of the nature of a reflex action, in which the fibres of the optic nerve act as sensory conductors to a centre in the brain, whence influences emanate which affect the pupil. The centre is in the neighbourhood of the nucleus of the third nerve, beneath the anterior pair of the corpora quadrigemina. On the other hand, the dilating fibres are derived from the sympathetic; and it has been shown that they come from the lower part of the cervical, and upper part of the dorsal, region of the cord. The iris in some animals is directly susceptible to the action of light.

The pupil *contracts* under the influence—(1) of an increased intensity of light; (2) of convergence of the two eyes, as in accommodating for a near object; and (3) of such active substances as nicotine, morphia and physostigmine. It *dilates* under the influence—(1) of a diminished intensity of light; (2) of vision of distant objects; (3) of a strong excitation of any sensory nerve; (4) of dyspnoea; and (5) of such substances as atropine and hyoscyamine. The chief function of the iris is so to moderate the amount of light entering the eye as to secure sharpness of definition of the retinal image. This it accomplishes by (1) cutting off the more divergent rays from near objects and (2) preventing the error of spherical aberration by cutting off divergent rays which would otherwise impinge near the margins of the lens, and would thus be brought to a focus in front of the retina.

3. SPECIFIC INFLUENCE OF LIGHT ON THE RETINA

The retina is the terminal organ of vision, and all the parts in front of it are optical arrangements for securing that an image will be accurately focused upon it. The natural, so-called adequate, stimulus of the retina is light. It is also excited by mechanical and electrical stimuli. It is said that such stimuli applied to the optic nerve behind the eye produce a luminous impression, but the evidence on this point is not conclusive. Pressure or electrical currents acting on the eyeball stimulate the retina and cause the sensation of flashes of light (phosphenes). The stimulus acts primarily upon the rods and cones (*vide supra* Purkinje's experiment), where it sets up nervous impulses which traverse successively the layers of the retina and the optic nerve fibres.

1. **Adaptation.**—We are all familiar with the experience that when we pass from a brightly-lighted room into a dimly-lighted one, we are unable for a time to distinguish the objects in the room. After a few minutes the brighter objects emerge and as time goes on, more and more can be distinguished. This is due to the fact that the sensitivity of the retina increases. It becomes maximal after the eyes have been kept completely shaded from all light for 30–40 minutes. This adaptation to dim light is called *dark adaptation.* If the sensitivity is accurately measured by determining the feeblest illumination which is capable of arousing the visual sensation, it is found that the rise is very rapid during the first 5 to 10 minutes and ultimately becomes many thousand times greater than that of the eye adapted to strong daylight illumination (*light adaptation*).

If the spectrum produced by a very feeble illumination is viewed by the dark adapted eye it is seen to be colourless. The neutral grey band, however, varies in brightness, the brightest part corresponding to about 530 $\mu\mu$, a part which under ordinary illumination appears green. Vision under these conditions has been called *scotoptic* or *twilight vision.* If the illumination is increased the eye rapidly becomes light adapted, and the colours appear in the spectrum (*photoptic vision*). The brightest part of the spectrum is then found to be about 580 $\mu\mu$ in the yellow.

If in a similar manner one takes a monochromatic light, say in the green or blue, and gradually increases the intensity from zero there is a considerable range of intensity before the colour appears. This is called the *photochromatic interval,* and it varies according to the wave-length of the light. It is so small at the red end of the spectrum that it is very difficult to prove its existence.

The shift of brightness, which is so striking, from the green region of the achromatic scotoptic spectrum to the yellow of the chromatic photoptic spectrum manifests itself throughout the spectrum. For instance, a red of 670 $\mu\mu$ viewed under conditions of light adaptation with moderate intensity of illumination may be ten times as bright as a blue of 480 $\mu\mu$ whereas if the illumination is decreased and the eye dark adapted there is a reversal of the relative brightnesses, and the blue is now 16 times as bright as the red. This phenomenon was discovered by Purkinje, and is known as *Purkinje's phenomenon.*

These are the changes which account for the difference in appearance of the colours in the landscape when twilight falls, or at dawn. As the light fails the reds disappear first, and geraniums and other red flowers look black, while violet and blue flowers retain some colour and appear relatively brighter than in daylight. Next, the greens fade away and the fields and hedges look grey.

The facts already mentioned suggest that vision under low illumination is carried out by a mechanism which differs from that of vision under higher illumination: and this view is supported by other facts.

Thus, we have seen that under ordinary illumination stimulation of the central part of the retina, especially the fovea and the surrounding macula lutea, gives rise to by far the most acute visual impressions. The reverse is the case under dim illumination and dark adaptation. The macular region becomes the least sensitive, and is indeed "night blind." This fact was discovered by astronomers long ago. If one looks directly at the Pleiades only four or five stars can be seen, but if one fixes a point a little to one side a number of weaker stars become visible. One can easily see on any starlight night that any star becomes unmistakably brighter if one looks at it slightly eccentrically. The famous French astronomer, Arago, expressed the fact paradoxically by saying that "in order to perceive a very dimly lighted object it is necessary not to look at it."

This phenomenon has a very important bearing upon the picking up of lights at sea at night, as was shown by some experiments of the late Prof. Gotch. Thus he found that "in the dark adapted eye red light is recognized as red over an area whose radius is three or four times that observed with green light; yet the red light is not seen at all outside this larger area. On the other hand, green (or blue) light, whilst it is only recognizable as green over the much more restricted central area, is seen as a bright light of a dazzling white type over a very extensive area."

If the mechanism which subserves scotoptic vision is different from that subserving photoptic the night blindness of the macular region should afford some clue as to its nature. Now the macular region is characterized by the absence of rods from the neuro-epithelium. It seems probable, therefore, that dim illumination excites the rods but fails to excite the cones, and that it is only when the intensity of the light is increased that the cones respond. If this be so, then the rods are the organs of scotoptic and the cones of photoptic vision. This is the so-called *Duplicity Theory.* It is further supported by some facts of comparative anatomy. In fact, it was first suggested by Schwalbe as the result of observations on the eyes of nocturnal animals, such as owls, which he found to have only rods in their retinae.

The rate at which the eyes become adapted to dim light varies somewhat in normal people, and there are diseased conditions in which it is very slow or almost absent. Such people are night-blind. They are practically incapacitated in dull lights, and cannot get about after dark. In one rare group the eyes appear to be otherwise normal and the disease is transmitted from one generation to another. The most famous and most extensive pedigree of any diseased condition is that of some congenitally night-blind people in the Montpellier district in the south of France. The pedigree was started by Cunier in 1838 and brought up to date in 1907 by Nettleship. It consists of ten generations of 2,121 persons, 135 of whom were night-blind. Much commoner is the night-blindness associated with the disease of the retina called retinitis pigmentosa.

An interesting antithesis to night-blindness is found in the rare cases of congenital total colour-blindness. As already mentioned, for the normal sighted the colourless grey spectrum of scotoptic vision becomes suffused with all the colours of the rainbow as the intensity of the light is increased. For the totally colour-blind, although the brightness increases under these conditions, no colours are seen. Moreover, there is no shift of the maximum brightness from the green to the yellow region of the spectrum, such as occurs in the normal.

On the Duplicity theory the congenital night-blind may be regarded as having only cone vision, and the totally colour-blind only rod vision. There are, however, difficulties in accepting this simple explanation.

2. **The Visual Purple.**—The facts relating to dark adaptation and the alteration in sensitivity of the retina on exposure to light throw some glimmer of light on the fascinating question how the physical stimulus is transformed into a physiological impulse which gives rise to the visual sensation. The obvious analogy of the photographic film predisposes one to the hypothesis that the radiant energy is absorbed by chemical substances in the retina, the alteration in these substances causing a transformation of energy into the physiological impulse—in other words, that the first step in the process is photo-chemical.

In 1851 H. Müller found a remarkable purple substance in the rods of the frog's retina which had been protected from the influence of light. In 1876 Boll discovered that this substance was bleached when exposed to light. Kühne, in 1878 and the succeeding years, investigated the substance exhaustively, and it was shown that after bleaching it became regenerated if the eye was again protected from light, but only if the retina was kept in contact with the still living or "surviving" cells of the retinal pigment epithelium. It would appear, therefore, that the substance is formed—or at any rate certain necessary precursors of the substance are formed—by the activity of the pigment cells, and that it is then absorbed by the rods.

More minute investigation of the process of bleaching of this so-called visual purple or rhodopsin has proved to be of great theoretical interest. It is found that the rate of bleaching varies with the nature of the light, so that if samples are bleached by monochromatic light of different wave-lengths the relative bleaching values can be determined. The wave-length 530 $\mu\mu$ is the most active, the values falling off on each side. We have already found that this wave-length is significant in another respect. It is the brightest part of the achromatic scotoptic luminosity curve; and if this curve is similarly plotted it is found that the two curves are identical within the limits of experimental error. It is impossible to resist the conclusion that so striking a coincidence must have a very definite meaning, viz., that the stimulation of the retina which gives rise to scotoptic vision is the result of the bleaching of the visual purple.

We have seen that when the intensity of the light is increased the eye becomes light adapted and the spectral colours appear; further, that the brightest part shifts to the yellow. These facts are less easily explained on the basis of a photo-chemical reaction in the visual purple, although such an explanation is not impossible. If the indications which give rise to the duplicity theory are correct, photoptic vision is carried out by the cones. Kühne and most other observers have failed to find any evidence of visual purple in the cones, and it is a striking fact that the part of the retina which contains only cones, viz., the rod-free macular area, is "night-blind," *i.e.*, it shows little power of adaptation to low illumination. Moreover, most observers agree that Purkinje's phenomenon is absent when the stimuli are confined to the rod-free area of the macula. The macular region, however, is not completely irresponsive to adaptation. It may be that the cones contain only a small amount of visual purple or that some more complex reactions occur in it when strong light stimuli are applied. It is highly improbable that rod and cone responses are fundamentally different in their mechanism. Both are doubtless photo-chemical reactions, but the exact explanation has not yet been satisfactorily elicited.

3. **Electrical Changes.**—Granted, however, that a photo-chemical change is the first step in the production of the physiological impulse, we are not much farther advanced in our knowl-

edge of that impulse. We know that nerve impulses in other nerves, both motor nerves, the stimulation of which sets muscles in activity, and other sensory nerves, such as those which subserve touch, are accompanied by a change in electrical potential which sets up electrial currents. These have been very thoroughly investigated by Keith Lucas and Adrian, who have proved that a stimulus either produces no electrical response at all or else the maximum response—the so-called "all-or-none principle." Recently Adrian has investigated the optic nerve of the conger eel in the same manner, and has shown that so far as the electrical response is concerned it agrees with that of other nerves. So that we now know something about the photo-chemical change and something about the changes which occur in the optic nerve. Interposed between them, however, is the very complex nervous mechanism of the retina, and it was long ago shown by Holmgren that the stimulus of light on the eye causes electrical changes of a complex nature in the retina.

Holmgren, Dewar, M'Kendrick, Gotch and others, have shown that when light falls on the retina it excites a variation of the electrical current obtained from the eye when placed on the cushions of a sensitive galvanometer. One electrode touches the vertex of the cornea and the other the back of the eyeball. The corneal vertex is positive to the back of the eye, or to the transverse section of the optic nerve. Consequently a current passes through the galvanometer from the cornea to the back. Then the *impact* of light causes an increase in the natural electrical current—during the *continuance* of light the current diminishes slowly and falls in amount even below what it was before the impact—and the *withdrawal* of light is followed by a rebound, or second increase, after which the current gradually returns to normal.

It was also observed in these researches that the amount of electrical variation produced by light of various intensities corresponded pretty closely to the results expressed by Fechner's law, which regulates the relation between the stimulus and the sensational effect in sensory impressions. This law is, that the sensational effect does not increase proportionally to the stimulus, but as the logarithm of the stimulus. Thus, supposing the stimulus to be 10, 100 or 1,000 times increased, the sensational effect will not be 10, 100 or 1,000 times, but only 1, 2 and 3 times greater.

4. **Regional Effects.**—The retina is not equally excitable in all its parts. At the entrance of the optic nerve, as was shown by E. Mariotte in 1668, there is no sensibility to light. Hence, this part of the retina is called the *blind spot*. If we shut the left eye, fix the right eye on the cross seen in fig. 12, and move the book towards and away from the eye, a position will be found when the round spot disappears, that is, when its image falls on the entrance of the optic nerve. There is also complete insensibility to colours at that spot. The diameter of the optic papilla is about 1·8 mm., equivalent to a visual angle of 6°; this angle determines the apparent size of the blind spot in the visual field, and it is sufficiently large to cause a human figure to disappear at a distance of two metres.

The *yellow spot* or *macula lutea* in the centre of the retina is the most sensitive to light, and it is chiefly employed in direct vision. Thus, if we fix the eye on a word in the centre of this line, it is distinctly and sharply seen, but the words towards each end of the line are vague. If we wish to see each word distinctly, we "run the eye" along the line—that is, we bring successive words on the yellow spot.

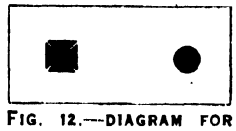

FIG. 12.—DIAGRAM FOR THE STUDY OF THE BLIND SPOT

5. **Persistence of Retinal Impressions.**—To excite the retina, a feeble stimulus must act for a certain time; when the retina is excited, the impression lasts after the cessation of the stimulus; but if the stimulus be strong, it may be of very short duration. Thus the duration of an electrical spark is extremely short, but the impression on the retina is so powerful, and remains so long, as to make the spark visible. If we rotate a disk having white and black sectors we see continuous dark bands. Even if we paint on the face of the disk a single large round red *spot*, and rotate rapidly, a continuous red *band* may be observed. Here the impressions of red on the same area of retina succeed each other so rapidly that before one disappears another is superadded, the result being a fusion of the successive impressions into one continuous sensation. This phenomenon is called the *persistence of retinal impressions*. An impression lasts on the retina from $\frac{1}{50}$ to $\frac{1}{80}$ of a second. The cinematograph owes its effects to persistence of retinal impressions.

The macular region is oval in shape, the vertical axis being about 1 mm. and the horizontal 3 mm., corresponding to visual angles of 4° and 12°. In the centre of it is a pit, the *fovea centralis*, which is the point of most distinct vision. It is 0·3 mm. in diameter, equal to a visual angle of 1°, and in it the layers of the retina are reduced to little but the neuroepithelium, which here consists only of slender elongated cones. Around the fovea is a rod-free area of about 0·8 mm. diameter, equal to a visual angle of 3°.

Visual acuity is sharpest at the point of fixation of the eye, the image of which falls upon the fovea. Here two mathematical points of light, such as two stars, can be discriminated as separate points if they subtend a visual angle of about 50 seconds of arc. This is equivalent to a retinal image of about $3{\cdot}2\mu$, which is the mean diameter of the foveal cones. Good visual acuity therefore agrees with the theoretical resolving power of the eye as an optical instrument and the fineness of grain of the recipient screen.

This is, however, not the maximum power of discrimination of the eye, for contours, such as the appreciation of difference of breadth of two bright lines, may be discriminated to about 10 seconds ($=0{\cdot}73\mu$) or less. Contour discrimination is used in physical measurements in the vernier. With binocular vision a break in the contour separating white and black surfaces can be discriminated if it subtends only 2 or 3 seconds of arc. The explanation is to be found in the greater sensitivity to change or difference in brightness of the parts of the diffusion circles which are always formed. These account also for *irradiation*, whereby a white square on a black background looks larger than the same sized black square on a white background.

The *field of vision* around the point of fixation extends more than 90° outwards, 70° downwards, 60° inwards and 50° upwards. It is smaller for colours of ordinary intensities, but the colour fields can be increased almost to the limits of the white field by suitable increase in the intensity of the light. With ordinary illumination and patches of coloured paper of 20 sq.mm. the blue field is about 10° smaller than the white, yellow rather smaller than blue, red 20° smaller than white, and green smaller still. Most colours change in hue as they pass from the fixation point towards the periphery; but certain spectral colours can be found which merely become paler or less saturated. These were called by Hess invariable colours. With them the blue and yellow are complementary colours (*vide infra*), and have the same sized field; and similarly the red and green.

6. **Recurrent Vision and Flicker.**—Not only is the response to an instantaneous flash of light longer than the stimulus, but it is often recurrent. In 1872 C. A. Young noticed that when a discharge from a powerful electric machine momentarily illuminates a room the objects may be seen not once only, but two or even three or four times in rapid succession, although the spark is single and instantaneous. The stimulus gives rise to series of pulses of sensation of diminishing intensity rapidly succeeding one another. They have been specially studied by William McDougall and others. The curves of sensation differ somewhat in time relations, which accounts for the occasional sensations of colour derived from pure black and white stimuli, as in Benham's top.

If the oscillations produced by intermittent stimulation are not sufficiently rapid to cause complete fusion, a sensation of flickering is felt. If black and white sectors are rotated with gradually increasing velocity there is first separate vision of the individual sectors. This is followed by a peculiarly unpleasant coarse flickering, which passes into a fine tremulous appearance, after which complete fusion occurs.

A large amount of work has been done upon flicker. Among the earlier researches the work of an Eton schoolmaster, T. C. Porter (1898) may be mentioned. With simple apparatus he

showed conclusively that what is called the critical frequency, *i.e.*, the rate of alternation of two lights of different intensity at which the sensation of flickering just disappears, is dependent entirely upon the luminosities of the lights and is independent of their colours or wave-lengths. This fact has been fully confirmed by Ives and many other observers, and is accepted as the principle of the flicker photometer. For obviously we have here an excellent method of hetero-chromatic photometry. It is much easier to say when flickering disappears than it is to say when two colours of different hue reach the same brightness—the so-called equality of brightness method. Moreover, each coloured light can be separately flickered against a known white light.

7. **Induction.**—The sensitivity of an area of the retina which is stimulated by light is thereby altered, so that a second stimulus applied to the same area does not have the same effect as it otherwise would have (*successive contrast*). Thus, if a square patch of red paper lying on a grey background is viewed for a few seconds and the gaze is then directed to a white surface a greenish patch will appear on the white surface. It follows that the stimulation with one colour makes the area less sensitive to that colour and more sensitive to the complementary colour. In fact, if the retina is stimulated with the purple light which is complementary to a particular green wave-length of the spectrum and is then stimulated with that green, an extremely vivid green—much greener than is ever experienced by any other means—is seen.

If the eye is kept closed in a dark room the sensation is not that of utter darkness, but a kind of very dark grey, due to what is called "the intrinsic light of the retina." If now a bright patch is looked at for a few seconds and the eyes then closed, an after-image of the same brightness as the original presentation may be seen, but is usually transitory (*positive after-image*). It is followed, or entirely replaced by a *negative after-image*, which appears as a much blacker patch in the midst of the surrounding grey. If the stimulus is coloured the positive after-image is of the same, the negative of the complementary hue.

The effects of induction are not limited to the area of retina stimulated. The sensitivity of the surrounding areas, and especially of those contiguous, are altered, and that in the opposite direction to that of the area stimulated. Hence a white patch on a black background looks brighter than when it is surrounded by grey, and the black itself looks blacker than if there were no white patch. Similarly, a red patch on a grey background causes the grey to look greenish. These effects, from the physiological point of view, are analogous to the reciprocal innervation of muscles which was discovered by Sir Charles Sherrington. He found that when a movement is made, *e.g.*, with the arm or eyes, the muscles which, when stimulated, cause the opposite movement are not merely passively relaxed but are actually inhibited, so that they become slacker than usual.

It is clear that this reciprocal action of one area of retina upon the neighbouring areas will facilitate the discrimination of contours. It will, in fact, have the same practical effect as if the retinal image were very much more sharply defined than it really is.

4. SENSATIONS OF COLOUR

1. **General Statement.**—Colour (*q.v.*) is a special sensation excited by the action on the retina of rays of light of a definite wave-length. On the most likely hypothesis as to the physical nature of light, colour depends on the rate of vibration of the luminiferous aether, and white light is a compound of all the colours in definite proportion. When a surface reflects solar light into the eye without affecting this proportion, it is white, but if it absorbs all the light so as to reflect nothing, it appears to be black. If a body held between the eye and the sun transmits light unchanged, and is transparent, it is colourless, but if translucent it is white. If the medium transmits or reflects some rays and absorbs others, it is coloured. Thus, if a body absorbs all the rays of the spectrum but those which cause the sensation of green, we say the body is green in colour; but this green can only be perceived if the rays of light falling on the body contain rays having the special rate of vibration required for this special colour. The part played by the light illuminating the surface and the way in which the colours of mixed pigments are produced are discussed under COLOUR.

Every colour has three qualities: (1) *hue*, or tint, such as red, green, violet; (2) *degree of saturation*, or purity, according to the amount of white mixed with the tint, as when we recognize a red or green as pale or deep; and (3) *luminosity*, or brightness as when we designate the tint of a red rose as dark or bright. Two colours are said to be identical when they are in agreement as to these three qualities.

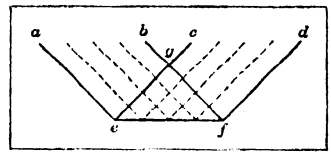

FIG. 13.—DIAGRAM OF DOUBLE SPECTRUM PARTIALLY SUPERPOSED

When we examine a spectrum, we see a series of colours merging by insensible gradations the one into the other, thus: Red, orange, yellow, green, blue and violet. These are termed *simple* colours. If two or more coloured rays of the spectrum act simultaneously on the same spot of the retina, they may give rise to sensations of *mixed colours*. These mixed colours are of two kinds: (1) those which do not correspond to any colour in the spectrum, such as purple and (2) those which do exist in the spectrum. White may be produced by a mixture of two simple colours, which are then said to be *complementary*. Thus, red and greenish blue, orange and cyanic blue, yellow and indigo blue, and greenish yellow and violet all produce white. Purple is produced by a mixture of red and violet, or red and bluish violet.

If we mix two simple colours not so far separated in the spectrum as the complementary colours, the mixed colour contains more white as the interval between the colours employed is greater, and if we mix two colours farther distant in the spectrum than the complementary colours, the mixture is whiter as the interval is smaller.

2. **Modes of Mixing Colour Sensations.**—Various methods have been adopted for studying the effect of mixing colours.

(*a*) *By Superposing Parts of Two Spectra*, fig. 13.

(*b*) *By Method of Reflection.*—Place a red wafer on *b*, in fig. 14, and a blue wafer on *d*, and so angle a small glass plate *a* as to transmit to the eye a reflection of the blue wafer on *d* in the same line as the rays transmitted from the red wafer on *b*. The sensation will be that of purple; and by using wafers of different colours, many experiments may thus be performed.

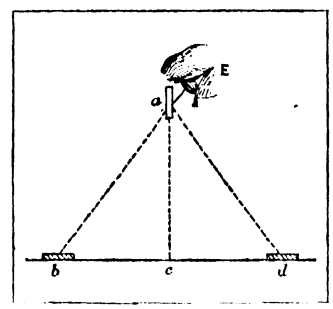

FIG. 14.—DIAGRAM SHOWING LAMBERT'S METHOD OF MIXING SENSATIONS OF COLOUR

(*c*) *By Rotating Discs Which Quickly Superpose on the Same Area of Retina the Impressions of Different Wave-lengths.*—Such discs may be constructed of cardboard, on which coloured sectors are painted, representing diagrammatically the arrangement attributed to Sir Isaac Newton. The angles of the sectors were thus given by him:

Red	60° 45·5′	Green	60° 45·5′
Orange	34° 10·5′	Blue	54° 41′
Yellow	54° 41′	Indigo	34° 10·5′
Violet	60° 45·5′		

With sectors of such a size, grey will be produced on rotating the disc rapidly. This method has been carried out with great efficiency by the colour-top of J. Clerk-Maxwell. It is a flat top, on the surface of which discs of various colours may be placed. Dancer has added to it a method by which, even while the top is rotating rapidly and the sensation of a mixed colour is strongly perceived, the eye may be able to see the *simple* colours of which it is composed. This is done by placing on the handle of the top, a short distance above the coloured surface, a thin black disc, perforated by holes of various size and pattern, and weighted a little on one side. The disc vibrates to and fro rapidly, and breaks the continuity of the colour impression; and thus the constituent colours are readily seen.

3. **The Laws of Colour Mixtures.**—The mixture of pure, *i.e.*, spectral, colour stimuli has been exhaustively studied by Newton, Grassmann, Clerk-Maxwell and many others, and has elicited the fact that *normal colour vision is trichromatic*. Thus, if three spectral hues are chosen, so far apart in the spectrum that neither can be reproduced by admixture of the other two, every conceivable light or light mixture gives rise to a sensation which can be accurately matched by the sensation produced by the mixture of suitable amounts of these three hues. The only exceptions to this law are that brown and olive green cannot be so reproduced without the assistance of successive contrast, which is equivalent to a mixture with black. And further, although accurate matches of *hue* are produced the hue produced by the admixture of the three lights is generally less saturated, in other words, a perfect match is only obtained by adding white to the comparison light.

It is thus possible to obtain innumerable *colour equations* representing accurately the results of such admixtures with a given spectrum. Hence, various methods for representing colours geometrically can be devised.

4. **The Geometric Representation of Colours.**—Colours may be arranged in a linear series, as in the solar spectrum. Each point of the line corresponds to a determinate impression of colour; the line is not a straight line, as regards luminous effect, but is better represented by a curve, passing from the red to the violet. This curve might be represented as a circle in the circumference of which the various colours might be placed, in which case the complementary colours would be at the extremities of the same diameter. Sir Isaac Newton arranged the colours in the form of a triangle, as shown in fig. 15. If we place three of the spectral colours at three angles, thus—green, violet and red—the sides of the triangle include the intermediate colours of the spectrum, except purple.

The point S corresponds to white, consequently, from the intersection of the lines which join the complementary colours, the straight lines from green to S, RS and VS represent the amount of green, red and violet necessary to form white; the same holds good for the complementary colours; for example, for blue and red, the line SB=the amount of blue, and the line SR=the amount of red required to form white. Again, any point, say M, on the surface of the triangle, will represent a mixed colour, the composition of which may be obtained by mixing the three fundamental colours in the proportions represented by the length of the lines M to green, MV and MR. But the line VM passes on to the yellow Y; we may then replace the red and green by the yellow, in the proportion of the length of the line MV, and mix it with violet in the proportion of SV. The same colour would also be formed by mixing the amount MY of yellow with MS of white, or by the amount RM of red with the amount MD of greenish blue.

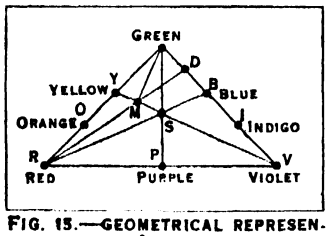

FIG. 15.—GEOMETRICAL REPRESENTATION OF THE RELATIONS OF COLOURS AS SHOWN BY NEWTON

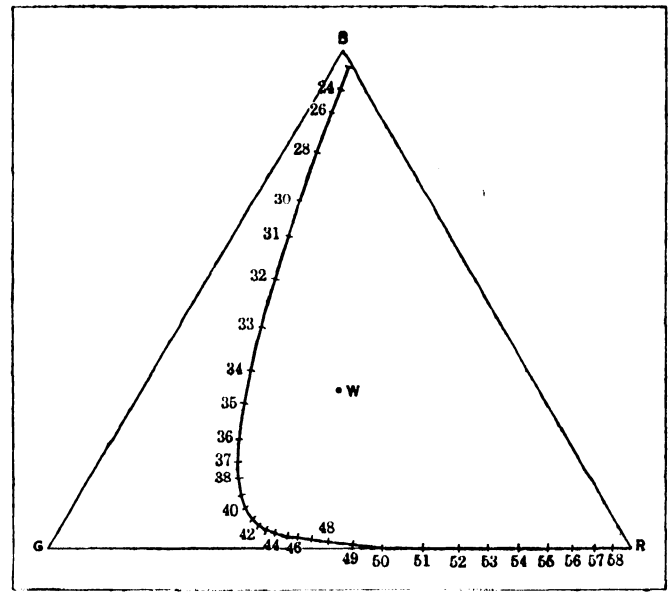


The triangle shown is purely diagrammatic. If measurements are made with any given spectrum the general form of the curve is triangular, the purples being strictly rectilinear. The lines from red to green and from green to violet, however, will be curved as in fig. 16.

The following list shows characteristic complementary colours, with their wave-lengths (λ) in millionths of a millimetre:

Red, λ656.	Blue-green, λ492.
Orange, λ608.	Blue, λ490.
Gold-yellow, λ574.	Blue, λ482.
Yellow, λ567.	Indigo-blue, λ464.
Greenish yellow, λ564.	Violet, λ433.

By combining colours at opposite ends of the spectrum, the effect of the intermediate colours may be produced; but the lowest and the highest, red and violet, cannot thus be formed. These are therefore fundamental or primary colours, colours that cannot be produced by the fusion of other colours. If now to red and violet we add green, which has a rate of vibration about midway between red and violet, we obtain a sensation of white. Red, green and violet are therefore regarded as the three fundamental colours.

5. **Physiological Characters of Colours.**—Colour physiologically is a sensation, and it therefore does not depend only on the physical stimulus of light, but also on the part of the retina affected. The power of distinguishing colours is greatest when they fall on, or immediately around, the yellow spot, where the number of cones is greatest. In these regions more than two hundred different tints of colour may be distinguished. As already mentioned, outside of this area lies a middle zone, where fewer tints are perceived, mostly confined to shades of yellow and blue. If intense coloured stimuli are employed, colours may be perceived even to the margin of the periphery of the retina, but with weak stimuli coloured objects may seem to be black, or dark like shadows. In passing a colour from the periphery to the centre of the yellow spot, remarkable changes in hue may be observed. Orange is first grey, then yellow, and it only appears as orange when it enters the zone sensitive to red. Purple and bluish green are blue at the periphery, and only show the true tint in the central region. Four tints have been found which do not thus change: a red obtained by adding to the red of the spectrum a little blue (a purple), a yellow of 574·5 λ, a green of 495 λ and a blue of 471 λ.

FROM SIR PARSON, "INTRODUCTION TO THE STUDY OF COLOUR VISION" (CAMBRIDGE UNIVERSITY PRESS)

FIG. 16.—COLOUR TRIANGLE; W. WHITE, R. RED, G. GREEN, B. BLUE The numbers are those of an arbitrary scale of the spectrum of the Arc Light (Abney & Watson)

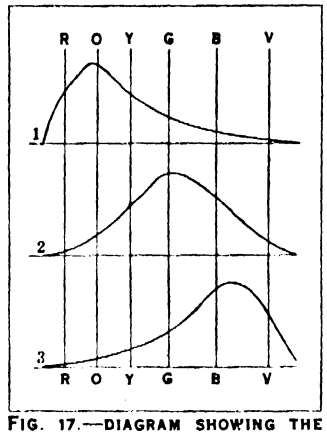
The question now arises, How can we perceive differences in colour? We might suppose a molecular vibration to be set up in the nerve-endings synchronous with the undulations of the luminiferous aether, without any change in the chemical constitution of the sensory surface, and we might suppose that where various series of waves in the aether corresponding to different colours act together, these may be fused together, or to interfere so as to give rise to a vibration of modified form or rate that corresponded in some way to the sensation. Or, to adopt another line of thought, we might suppose that the effect of different rays (rays differing in frequency of vibration and in physiological effect) is to promote or retard chemical changes in the sensory surface, "which again so affect the sensory nerves as to give rise to differing states in the nerves and the nerve centres, with differing concomitant sensations." The former of these thoughts is the foundation of the Young-Helmholtz theory, while the latter is applicable to the theory of E. Hering.

6. **The Young-Helmholtz Theory.**—A theory widely accepted by physicists was first proposed by Thomas Young and

afterwards revived by Helmholtz. It is based on trichromatism of normal colour vision and the assumption that three kinds of nervous elements exist in the retina, the excitation of which give respectively sensations of red, green and violet. These may be regarded as fundamental sensations. Homogeneous light excites all three, but with different intensities according to the length of the wave. Thus long waves will excite most strongly fibres sensitive to red, medium waves those sensitive to green, and short waves those sensitive to violet. Fig. 17 shows diagrammatically the irritability of the three sets of fibres. Helmholtz thus applies the theory:

1. Red excites strongly the fibres sensitive to red and feebly the other two—sensation: *Red*.
2. Yellow excites moderately the fibres sensitive to red and green, feebly the violet—sensation: *Yellow*.
3. Green excites strongly the green, feebly the other two—sensation: *Green*.
4. Blue excites moderately the fibres sensitive to green and violet, and feebly the red—sensation: *Blue*.
5. Violet excites strongly the fibres sensitive to violet, and feebly the other two—sensation: *Violet*.
6. When the excitation is nearly equal for the three kinds of fibres, then the sensation is *White*.

According to the Young-Helmholtz theory, there are three fundamental colour sensations, red, green and violet, by the combination of which all other colours may be formed, and it is assumed that there exist in the retina three kinds of nerve elements, each of which is specially responsive to the stimulus of waves of a certain frequency corresponding to one colour, and much less so to waves of other frequencies and other colours. If waves corresponding to pure red alone act on the retina, only the corresponding nerve element for red would be excited, and so with green and violet. But if waves of different frequencies are mixed (corresponding to a mixture of colours), then the nerve elements will be set in action in proportion to the amount and intensity of the constituent excitant rays in the colour. Thus if all the nerve elements were simultaneously set in action, the sensation is that of white light; if that corresponding to red and green, the resultant sensation will be orange or yellow; if mainly the green and violet, the sensation will be blue and indigo. No such nerve fibres or elements are known, but the theory is equally valid if the stimuli affect three photo-chemical substances, etc.



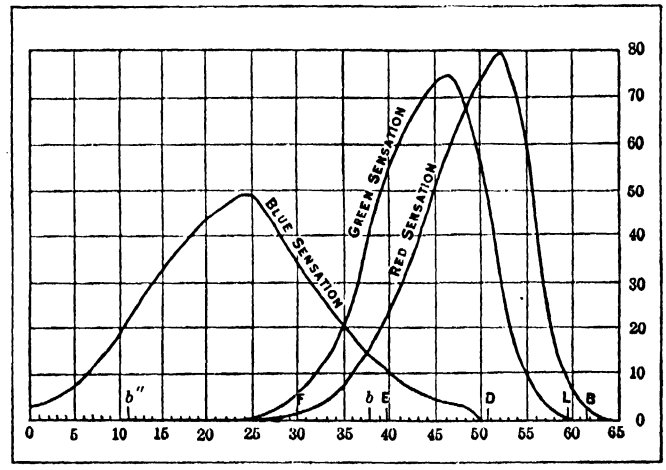


FIG. 17.—DIAGRAM SHOWING THE IRRITABILITY OF THE THREE KINDS OF RETINAL ELEMENTS

Seeing that the Trichromatic theory or Three Components theory, as the Young-Helmholtz theory is better termed, depends upon the trichromatism of normal colour vision it is clear that the three so-called *sensation curves* can be deduced from colour equations. This was first done by Clerk-Maxwell, and at a later date by König, an assistant of Helmholtz. They have since been worked out by Abney by a different method, dependent upon the fact that the brightness of the unanalysed white light is equal to the sum of the brightnesses of all the individual wave-lengths of the spectrum. Abney's curves are shown in fig. 18.

None of the curves extends at both ends to the limits of the spectrum, as is demanded by the theoretical curves; but it must be remembered that at the ends of the spectrum it is extremely difficult to make accurate matches, owing to the low luminosity.

7. **The Opponent Colours Theory.**—If one regards the spectrum psychologically and independent of any physical preconceptions one notes that there are only four fundamentally unique colour sensations, viz., red, yellow, green and blue. The intermediate spectral colours partake of the nature of each of their neighbours, *e.g.*, orange, which manifestly arouses a sensation reminiscent of both red and yellow; yellowish-green; greenish-blue; etc. Violet to most people resembles blue mixed with a tinge of red, and the purples outside the spectrum are all mixtures of red and blue or violet. From the psychological point of view, therefore, there appear to be four, rather than three, fundamental colours.

Moreover, these four are two pairs of complementary colours, and may therefore be regarded as in some sense opposed to each other. Psychologically, black is opposed to white, but whereas the greys form a continuous series from white to black, no such continuous series links red with green, or yellow with blue.

FROM ABNEY, "RESEARCHES IN COLOUR VISION" (LONGMANS GREEN & CO.)

FIG. 18.—ABNEY'S R G & B EQUAL AREA SENSATION CURVES
The sums of equal ordinates of the three curves at any point represent the sensation of the unanalysed white light

The facts of induction—simultaneous and successive contrast—elicit the opponent effects of these pairs of toned or coloured and untoned or colourless sensations. On grounds of this nature, Hering propounded his theory of colour vision, which may be called the Opponent Colours theory. It is really a part of a more general metabolic theory of physiological processes. Hering hypothecates three different visual substances, white-black, red-green, and yellow-blue substances, which exist somewhere in the sub-cortical visual paths. He supposes that when a living substance is protected from external stimuli it undergoes spontaneous *autonomous* metabolic changes. Some molecules break down or undergo dissimilation (or katabolism), fresh ones are built up or undergo assimilation (or anabolism). When the two processes balance each other the substance is in a state of *autonomous equilibrium*. It is to be noted that autonomous equilibrium does not necessarily mean physiological inactivity. Fresh formative matter may be brought from the blood in the exact quantity necessary to replace the formed matter which is poured out into the blood. If the substance is acted upon by an external stimulus *allonomous* metabolic changes are set up. They may be either anabolic or katabolic, but they induce a spontaneous tendency in the opposite direction so as to reproduce autonomous equilibrium, *i.e.*, allonomous katabolism, for example, induces autonomous anabolism. With constant stimulation the autonomous anabolism becomes equal to the allonomous katabolism, and a new condition of equilibrium at a lower potential is set up, which is called *allonomous equilibrium*. Upon removal of the stimulation autonomous anabolism will prevail for a time until autonomous equilibrium is again set up.

Hering supposes that when rays of a certain wave-length fall on visual substances assumed to exist in the retina, katabolic changes occur, while rays having other wave-lengths cause constructive or anabolic changes. Suppose that in a red-green substance katabolic and anabolic changes occur in equal amount, there may be no sensation, but when waves of a certain wave-length or frequency cause katabolic changes in excess, there will be a sensation of red, while shorter waves and of greater frequency, by exciting anabolic changes, will cause a sensation of green: and so on.

8. **The Two Theories Compared.**—Hering's theory accounts satisfactorily for the formation of coloured after-images. Thus, if we suppose the retina to be stimulated by red light, katabolism takes place, and if the effect continues after withdrawal of the red

stimulus, we have a positive after-image. Then anabolic changes occur under the influence of nutrition, and the effect is assisted by the anabolic effect of shorter wave-lengths, with the result that the negative after-image, green, is perceived. Perhaps the distinctive feature of Hering's theory is that white is an independent sensation, and not the secondary result of a mixture of primary sensations, as held by the Young-Helmholtz view. The greatest difficulty in the way of the acceptance of Hering's theory is with reference to the sensation of black. Black is held to be due to anabolic changes occurring in the white-black substance. Suppose that anabolism and katabolism of the white-black substance are in equilibrium, unaccompanied by stimulation of either the red-green or the yellow-blue substances, we find that we have a sensation of darkness, but not one of intense blackness. This "darkness" has still a certain amount of luminosity, and it has been termed the "intrinsic light" of the retina. Sensations of black differing from this darkness may be readily experienced, as when we expose the retina to bright sunshine for a few moments and then close the eye. We then have a sensation of intense blackness, which soon, however, is succeeded by the darkness of the "intrinsic light." The various degrees of blackness, if it is truly a sensation, are small compared with the degrees in the intensity of whiteness. In the consideration of both theories changes in the cerebral centres have not been taken into account, and of these we know next to nothing.

It is, perhaps, natural that the three components theory has always appealed most strongly to physicists, while physiologists have in the past been inclined most to support the opponent colours theory. The latter can be made to explain the facts of induction; but, even though it is obviously founded largely upon these facts, it has to be strained considerably to account for their details. It does not, however, so satisfactorily explain the facts of colour mixture. On the other hand, the Young-Helmholtz theory accounts admirably for the facts of colour mixture, upon which it was founded, whereas Helmholtz had to resort to psychological illusions of "judgment" to make it account for the facts of induction. As McDougall, however, has shown, it accounts quite well for most of these facts also.

Space does not permit of a description of the many other theories of colour vision which have been brought forward. (*See* Parsons, *An Introduction to the Study of Colour Vision*, 2nd ed., Cambridge, 1924).

9. **Colour-blindness.**—It has long been known that many persons show peculiarities of colour vision distinguishing them from the normal. The earliest reference in the literature is that of Turberville in the *Transactions* of the Royal Society (1684). The first case exhaustively studied was that of John Dalton, the chemist, and colour-blindness was long known as "Daltonism."

Nearly all these people have difficulty in discriminating between reds and greens and other colours at this end of the spectrum. The most pronounced cases fall into two groups: in one vivid reds are confused with dark greens; in the other greens are confused with red, orange and yellow of more equivalent brightness.

In 1881 Lord Rayleigh discovered that many people with apparently normal colour vision require different amounts of red or green in making colour matches. His crucial test was the matching of the yellow of the sodium lime (589 $\mu\mu$) with a mixture of lithium red (670 $\mu\mu$) and thallium green (527 $\mu\mu$). This is the test used in Nagel's Anomaloscope.

All these varieties, and possibly some others, are of congenital origin and incurable. The statistics are very unreliable, but the grosser cases affect about 4% of males and 0·4% of females. The disease is hereditary and generally transmitted through the female, who is herself not usually affected.

Owing to the use of red, green and white lights for signalling on railways, ships, etc., the elimination of the colour-blind from candidates for posts of engine driver, navigating officers, and so on, is of the utmost importance.

Defects of colour vision—acquired colour-blindness—occur in various diseases of the visual apparatus, notably in toxic amblyopia produced by tobacco and other drugs. In these cases the defect is often limited to the area around the fixation point—central colour scotoma—and in all cases differs materially from congenital colour-blindness.

A few cases of uniocular congenital colour-blindness have been described, but none is sufficiently well authenticated to decide the question as to exactly what are the sensations which the colour-blind experience. We have no means of discovering the sensations of other people except by comparison with our own responses and inferences derived therefrom. We are all equipped with an extensive vocabulary of colour names, and the colour-blind, guided by shapes, variations in brightness, and other adventitious aid, often call objects by their right colours. They never call a strawberry green, but they may have the greatest difficulty in finding the strawberries on the plants, and they find it more economical to use yellow pegs to tee their ball at golf than red ones. Hence, in the investigation of the nature of the defect in any individual, little credence is to be attached to the colour nomenclature they employ, though the expert examiner will obtain some evidence from it. On the other hand, in determining the fitness of sailors and railway men colour naming is important, for a man who calls a red light green is obviously unfit to be an engine driver.

One of the most efficient means of testing the sensations of the colour-blind is to compare their matching of colours with that of the normal person. Owing to the complexity of the light reflected from different coloured objects false deductions are easily made if these are used. They will suffice to discover colour-blindness in bad cases, but may fail to reveal it in others. Hence, no examination is exhaustive unless spectral colours are employed.

10. **Dichromatic and Trichromatic Vision.**—If a large number of cases is examined in this manner a group of very bad cases can be segregated which have this common characteristic:—Two monochromatic lights can be found such that, mixed in various proportions, the mixtures will match every wave-length throughout the spectrum and also the unanalysed white light. In order to get perfect matches it will be necessary only to alter the relative brightnesses of the pure and the mixed stimuli. In this group two well-marked sub-groups can be distinguished, as was discovered by Seebeck (1837). They differ in the proportions of the two mixed lights which are required for the matches. Since normal individuals require three colours to make such matches, and are hence called trichromatic, these colour-blind people are aptly called *dichromats*. As much confusion has arisen from the names applied to the two groups, we will temporarily call them *A* and *B*.

Since white light can be matched by the dichromat with a suitable mixture of two monochromatic lights, and since all spectral colours can be matched by mixing the same two colours in various proportions, it follows that there is some spectral colour which will match white. This is called the *neutral point* of the dichromatic spectrum. In group *A*, it is at about 489 $\mu\mu$, in group *B* at about 500 $\mu\mu$: both neutral points are therefore in the bluish green region of the spectrum. Since there is a purple, outside the spectrum and composed of a suitable mixture of red and violet, which is complementary to this green, it is obvious that there must be a neutral point in the purples; and such is found to be the case.

A further discovery of profound theoretical importance was made by Seebeck, viz., that all colour equations valid for normal vision are also valid for dichromatic vision, or colour matches which are valid for the trichromatic are also valid for the dichromatic eye. Hence it follows that the dichromat possesses no variable which the trichromat lacks, but lacks a variable which the trichromat possesses. In other words, dichromatic vision is a *reduction form* (von Kries) of normal vision, and not a fundamentally different kind of vision.

If the spectral matches of dichromats with mixtures of red (645 $\mu\mu$) and blue (461 $\mu\mu$) are plotted with the spectral wave-lengths as abscissae and the amounts required (on an arbitrary scale) as ordinates, it is found that no blue is required on the red side of 530 $\mu\mu$ (von Kries). The two groups are sharply distinguished. In the *A* group the red maximum is at 571 $\mu\mu$ and falls rapidly towards the red end, showing the low stimulus value for long-wave light. This is shown in many cases by an actual

inability to see the red end of the spectrum as seen by the normal —*shortening of the red end of the spectrum.* In the *B* group the red maximum is at 603 $\mu\mu$ and falls more slowly towards the red end. Hence Rivers (1900) introduced the terms *scoterythrous* and *photerythrous* to distinguish the *A* and *B* groups. It is unfortunate that these terms have not been generally adopted, since they are purely descriptive and are independent of any theory. It follows, and has been amply confirmed by experiment, that the luminosity curve of the spectrum of the *B* group resembles nearly that of the normal trichromat, whereas the maximum of the luminosity curve of the *A* group is displaced towards the green.

11. **Theories of Colour-blindness.**—Most investigators of colour-blindness have been imbued with some particular theory of colour vision and have expressed their views in terms of the theory. Thus, Helmholtz, deeply impressed by the fact that dichromatic vision is a reduction form of trichromatic and that trichromatic colour equations are valid for the dichromats, concluded that this form of colour-blindness could be explained by the absence of one of the three components. The sensation curves are usually denominated by the colour region of their maximum effects—red, green and blue. Hence he concluded that in the *A* group the red component was absent, in the *B* group the green. If this were the case, there might theoretically be two other forms of colour-blindness. In one the blue curve would be absent (*C* group), and in the other all the three curves might be fused in a central curve (*D* group). If such were the case, the *C* group would have relatively normal colour reactions as regards the red and green parts of the spectrum, but would confuse blues and yellows. In the *D* group the individuals would merely have varying sensations of brightness and no capacity for distinguishing colours at all. Now, there is a well known group of people who are *totally colour-blind,* and these fit in well with the theory. More recent research tends to show that they cannot all, at any rate, be explained in this manner. A relatively small number of cases has been described which conform to the requirement of the *C* group.

It was, perhaps, natural that the three groups of partial colour-blinds should be denominated red-blind, green-blind and blue-blind by upholders of the Young-Helmholtz theory. It has, however, had the most disastrous results and has led to endless ambiguity. For in the obvious meaning of the terms these people are not red-, green- or blue-blind. They simply have different responses from the normal when their retinae are stimulated with these particular regions of the spectrum. The attempt of von Kries to eliminate the ambiguity by calling the conditions *protanopia, deuteranopia* and *tritanopia* failed in its object, and seems only to have infuriated opponents of the Young-Helmholtz theory.

The explanation of the ordinary cases of partial colour-blindness on the Hering theory is that both groups, *A* and *B,* are due to absence of the red-green substance, the differences in the groups being attributed to differences in macular pigmentation. It is easy to prove that physical absorption by a pigment in the retina could not account for the facts, and no satisfactory explanation in terms of this theory has yet been brought forward.

There is no doubt that wide variations in the degree of partial colour-blindness occur, and the majority of the colour-blind people cannot make perfect matches of monochromatic spectral hues with only two fundamental colours. In other words, they are not completely dichromatic. Most fall into the category of those discovered by Lord Rayleigh, but it is highly probable that this group is really composite. They are obviously trichromatic, but most of them show, on exhaustive examination reactions which approximate them to one or other group of dichromats, chiefly to group *B.* They also can be found to have no new variable, and normal trichromatic matches are valid for them. They can therefore be explained on the Young-Helmholtz theory on the hypothesis that their responses to one or other of the fundamental components are less intense than normal; *i.e.,* while two of the sensation curves are normal, the third, either the "red" or the "green" is abnormally low. These cases are aptly called *anomalous trichromats,* and are sub-divided, in the terminology of von Kries, into *protanomalous* and *deuteranomalous.*

Abney and Watson have described a group of anomalous trichromats which differs fundamentally from all other cases of colour-blindness described above, in that they are not a reduction form. All the comparatively small number of cases hitherto investigated can be explained by a shift of the normal "green" sensation curve 2 or 3 $\mu\mu$ towards the red end of the spectrum.

It is beyond the scope of this article to discuss the many other theories of colour vision and their relation to colour-blindness. The Young-Helmholtz theory has fulfilled the essential function of a scientific hypothesis in inspiring new modes of investigation. Whether it be ultimately proved to embody the fundamental truth or not it possesses the merit of having elicited more knowledge on the subject than any other theory. Other theories must be evaluated in the light of those facts.

12. **Tests for Colour-blindness.**—These should be considered according to their aim, whether it be that of defining accurately the scientific nature of the type of colour-blindness, or merely to determine whether the individual is suited for a particular occupation. In most cases they are designed for the latter purpose, but it cannot be too strongly insisted that, though many cases of colour-blindness are easy to detect, others, which are equally dangerous, may need the most exhaustive investigation.

The matching of pigments in the form of coloured skeins of wool (Holmgren's test), etc., will often reveal bad cases, and in the hands of an expert examiner will raise suspicions in milder cases which further tests will confirm. The prejudice against Holmgren's wools is to some extent justified. Sailors object to a test so "unpractical" and savouring of effeminacy. Moreover, as already mentioned, pigments do not provide very satisfactory test objects.

Lantern tests have found greater favour, but may easily prove fallacious. The chief adventitious aid to the discrimination of colours by the colour-blind is their relative brightness. Thus, if a red light is shown amongst others to a member of group *A,* it will appear to him very dull, and he will probably name it correctly. In the Board of Trade lantern this adventitious aid was eliminated by *making all the lights of the same luminosity.* A similar effect can be produced in the Edridge-Green lantern by combining the coloured glasses with dimming glasses.

Stilling's isochromatic plates are a useful rough test. Ishiwara's are interesting in that they have designs which can be discriminated by the colour-blind but not by the normal.

Nagel's anomaloscope is a convenient method of applying Lord Rayleigh's test. It is liable to give erroneous results with people who are not accustomed to looking through a telescope.

In difficult cases—and there are many such—examination with various spectral tests is necessary. These may fittingly begin by the candidate delimiting with shutters the number of monochromatic patches in the spectrum, as advocated by Edridge-Green. More detailed tests by various spectral matches are best carried out by a projection method, such as Abney's, which eliminates the errors liable to arise with telescopic observation.

(X.; J. H. P.)

5. THE MOVEMENTS OF THE EYE

1. **General Statement.**—The globe of the eye has a *centre of rotation,* which is not exactly in the centre of the optic axis, but a little behind it. On this centre it may move round *axes of rotation,* of which there are three—an antero-posterior, a vertical and a transverse. In normal vision, the two eyes are always placed in such a manner as to be fixed on one point, called the *fixed point* or the *point of regard.* A line passing from the centre of rotation to the point of regard is called the *line of regard.* The two lines of regard form an angle at the point of regard, and the base is formed by a line passing from the one centre of rotation to the other. A plane passing through both lines of regard is called the *plane of regard.* With these definitions we can now describe the movements of the eyeball, which are of three kinds: (1) *First position.* The head is erect, and the line of regard is directed towards the distant horizon. (2) *Second position.* This indicates all the movements round the transverse and horizontal axes. When the eye rotates round the first, the line of regard is displaced

above or below, and makes with a line indicating its former position an angle termed by Helmholtz the angle of vertical displacement, or the *ascensional angle;* and when it rotates round the vertical axis, the line of regard is displaced from side to side, forming with the median plane of the eye an angle called the *angle of lateral displacement.* (3) *Third order of positions.* This includes all those which the globe may assume in performing a rotatory movement along with lateral or vertical displacements. This movement of rotation is measured by the angle which the plane of regard makes with the transverse plane, an angle termed the *angle of rotation* or of *torsion.*

The two eyes move together as a system, so that we direct the two lines of regard to the same point in space.

The eyeball is moved by six muscles, which are described in the article EYE (*Anatomy*).

The term *visual field* is given to the area intercepted by the extreme visual lines which pass through the centre of the pupil, the amount of dilatation of which determines its size. It follows the movements of the eye, and is displaced with it. Each point in the visual field has a corresponding point on the retina, but the portion, as already explained, which secures our attention is that falling on the yellow spot.

2. **Simple Vision with Two Eyes.**—When we look at an object with both eyes, having the optic axes parallel, its image falls upon the two yellow spots, and it is seen as one object. If, however, we displace one eyeball by pressing it with the finger, then the image in the displaced eye does not fall on the yellow spot, and we see two objects, one of them being less distinct than the other. It is not necessary, however, in order to see a single object with two eyes that the two images fall on the two yellow spots; an object is always single if its image falls on *corresponding points* in the two eyes.

The eye may rotate round three possible axes, a vertical, horizontal and antero-posterior. These movements are effected by four straight muscles and two oblique. The four straight muscles arise from the back of the orbit, and pass forward to be inserted into the front part of the eyeball, or its equator, if we regard the anterior and posterior ends of the globe as the poles. The two obliques (one originating at the back of the orbit) come, as it were, from the nasal side—the one goes above the eyeball, the other below, while both are inserted into the eyeball on the temporal side, the superior oblique above and the inferior oblique below. The six muscles work in pairs. The internal and external recti turn the eye round the vertical axis, so that the line of vision is directed to the right or left. The superior and inferior recti rotate the eye round the horizontal axis, and thus the line of vision is raised or lowered. The oblique muscles turn the eye round an axis passing through the centre of the eye to the back of the head, so that the superior oblique muscle lowers, while the inferior oblique raises, the visual line. It was also shown by Helmholtz that the oblique muscles sometimes cause a slight rotation of the eyeball round the visual axis itself. These movements are under the control of the will up to a certain point, but there are slighter movements that are altogether involuntary. Helmholtz studied these slighter movements by a method first suggested by F. C. Donders. By this method the apparent position of after-images produced by exhausting the retina, say with a red or green object, was compared with that of a line or fixed point gazed at with a new position of the eyeball. The ocular spectra soon vanish, but a quick observer can determine the coincidence of lines with the spectra. After producing an after-image with the head in the erect position, the head may be placed into any inclined position, and if the attention is then fixed on a diagram having vertical lines ruled upon it, it can easily be seen whether the after-image coincides with these lines. As the after-image must remain in the same position on the retina, it will be evident that if it coincides with the vertical lines there must have been a slight rotation of the eyeball. Such a coincidence always takes place, and thus it is proved that there is an involuntary rotation. This minute rotation enables us to judge more accurately of the position of external objects.

3. **The Horopter.**—This is the locus of those points of space which are projected on retinal points. While geometrically it may be conceived as simple, as a matter of fact it is generally a line of double curvature produced by the intersection of two hyperboloids, or, in other words, it is a twisted cubic curve formed by the intersection of two hyperboloids which have a common generator. The curves pass through the nodal point of both eyes. An infinite number of lines may be drawn from any point of the horopter, so that the point may be seen as a single point, and these lines lie on a cone of the second order, whose vertex is the point. When we gaze at the horizon, the horopter is really a horizontal plane passing through our feet. The horopter in this instance is the ground on which we stand. Experiments show "that the forms and the distances of these objects which are situated in, or very nearly in, the horopter, are perceived with a greater degree of accuracy than the same forms and distances would be when not situated in the horopter" (M'Kendrick, *Life of Helmholtz,* 1899, p. 172 *et seq.*).

An object which is not found in the horopter, or, in other words, does not form an image on corresponding points of the retinae, is seen double. When the eyeballs are so acted upon by their muscles as to secure images on non-corresponding points, and consequently double vision, the condition is termed *strabismus,* or squinting, of which there are several varieties treated of in works on ophthalmic surgery. It is important to observe that in the fusion of double images we must assume, not only the correctness of the theory of corresponding points of the retina, but also that there are corresponding points in the brain, at the central ends of the optic fibres. Such fusion of images may occur without consciousness—at all events, it is possible to imagine that the cerebral effect (except as regards consciousness) would be the same when a single object was placed before the two eyes, in the proper position, whether the individual were conscious or not. On the other hand, as we are habitually conscious of a single image, there is a psychical tendency to fuse double images when they are not too dissimilar.

4. **Binocular Perception of Colour.**—This may be studied as follows. Take two No. 3 eye-pieces of a Hartnack's microscope, or two eye-pieces of the same optical value from any microscope, place one in front of each eye, direct them to a clear window in daylight, keep them parallel, and two luminous fields will be seen, one corresponding to each eye. Then converge the two eye-pieces, until the two luminous circles cross, and the central part, like a bi-convex lens, will appear clear and bright, while the outer segments will be much less intense, and may appear even of a dim grey colour. Here, evidently, the sensation is due to a fusion of impressions in the brain. With a similar arrangement, blue light may be admitted by the one eye-piece and red by the other; and on the convergence of the two, a resultant colour, purple, will be observed. This may be termed the binocular vision of colours. It is remarkable that by a mental effort this sensation of a compound colour may be decomposed into its constituents, so that one eye will again see blue and the other red.

(X.; C. Go.)

6. VISUAL PERCEPTION

Visual impressions play a more important part than sensations of any other mode in guiding our interpretations of the external world and our orientation therein.

(a) **Visual Perception of Movement.**—Response to movement is the most primitive of all visual reactions. An observer may respond to visually presented movement, with only the vaguest apprehension of the direction and extent of the movement, and with no appreciation of the size, contours or colour of the moving object.

The visual appreciation of movement probably depends primarily upon the setting up of specific functional relationships between two or more groups of retinal sensory elements. If a retinal area is stimulated by a stationary point source, and thereafter a neighbouring area is similarly stimulated, and if the time and space relations between the two stimuli are suitably arranged, there results an impression, not of two stationary points, but of a single point in motion.

Most of the other functions of vision, the "object" reference, the localisation of objects, the attribution of size, contour and distance may be regarded as in some way bound up with the response to movement. In the course of development, however, they come to have independent status.

(b) **The "Object" Reference in Vision.**—When we see anything, normally a large number of visual impressions are involved. These are synthesised, or integrated, treated as having some common origin, and referred to an external source which we call the "object." There is no real explanation of this "object" reference which appears to be inherent in visual response; it is bound up with the ultimate "projicient" character of all visual experience.

(c) **Visual Localisation.**—In general visual impressions are interpreted as referring outward to some position in space. There are three principal directions, the transverse, giving us breadth, the vertical, giving us height, and the sagittal, giving us depth or distance. Broadly speaking localisation in any of these directions is possible only when the point or area localised has a background out of which other points may be selected and used as points of reference. Some of the data for such localisation are given by the afferent sensations which arise as the eyes move from one point to another over this background, or the lens is accommodated for nearer or farther points in the field of view. Such movements and accommodation are automatic and practically reflex; but if they are to be made at all accurately there must be some retinal, or at least visual, cue to them. Thus it is often assumed that for each point or group of points of retinal stimulation there must be a "local sign," by virtue of which any stimulus affecting them is at once given a position above or below, to the right or to the left, and, in reference to some point of fixation, forward or backward. Obviously this affords no explanation of visual localisation, but is only a way of stating how fundamental is such "positional" reference in vision.

A single luminous point exposed in a dark room can still to some extent be localised. For all of such observations every adult observer has a more or less definite preformed visual "scheme," and this may give him his necessary points of reference even though the latter are not, strictly speaking, visually presented.

Monocular perception of depth, distance or solidity is in any case exceedingly faulty. It is here that the development of binocular vision has its most important function. The data are given by sensations of convergence and divergence of the two eyes, by accommodation of the lens, and by the "local sign" system in relation to a point of fixation. For anything but fairly near distances, however, it is accurate to speak of perception. Judgment then comes into play, based upon all sorts of facts such as the clearness of the atmosphere, the apparent size of objects, the nature of intervening objects, the knowledge that we have already gained in other ways as to the spatial characteristics of whatever is being localised.

(d) **Apparent Size in Vision.**—For small objects apparent size depends in part, though less than might be expected, upon the size of the retinal image, as determined by the visual angle. Accommodation factors come in also, and normally contrast effects, derived from the relation of the object to its surroundings, are important. In the case of larger objects, eye movements may help to determine apparent size, together with contrast effects, and with complex psychological effects of the "schematic" order.

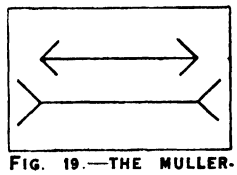

FIG. 19.—THE MULLER-LYER ILLUSION

(e) **Contour or Form Perception.**—Reaction to contour, or to form tends to become by far the most striking and persistent function of developed vision. In fact nearly all the common methods of measuring visual "acuity" applied to the adult human subject are tests of the capacity to distinguish the forms of objects. Usually this is held at bottom to rest upon the power of the eye to discriminate two points of light as distinct one from the other. But as a matter of fact the response to shape depends upon a most complex mass of physical, physiological and psychological factors. Very important indeed in this connection are the phenomena of simultaneous contrast by means of which contours may be differentiated from the background upon which they appear. Perception of form is an outstanding illustration of how a complex biological function cannot be explained in terms simply of the various unitary reactions by the combination of which it has been made possible.

(f) **Colour Perception.**—Colour perception, like that of form, is mainly a function of highly-developed and complex visual response. The various theories which have been put forward to account for the perception of colour are discussed elsewhere, but it should here be noted that in everyday life our perception, or judgment, of the colour of objects depends as much upon representational as upon immediate sensory effects. Thus snow may continue to look white even when, from a purely sensory point of view, it should be more red than other objects which are simultaneously seen as red.

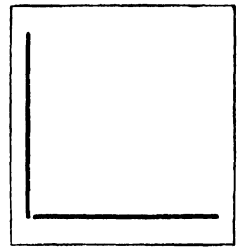

FIG. 20.—ZOLLNER'S FIGTAL-VERTICAL ILLUSION

(g) **Optical Illusions.**—An enormous literature has grown up around the detailed investigation of optical illusions. Some of the commonest are:

Of two equal horizontal lines, one terminated by arrow heads and the other by feather heads, the second appears longer than the first (fig. 19).

Of two equal lines, one vertical and the other horizontal, the vertical appears the longer (fig. 20).

Two parallel lines may be made to appear to converge or diverge by a series of short lines crossing the parallels at an acute angle (fig. 21).

A filled distance appears longer than an equal unfilled distance. There are many other visual illusions of form, direction, distance and movement. No single explanation of them all is possible and perhaps the most valuable conclusion that can be drawn from their investigation is a further reinforcement of the truth that visual perception is a highly complex integration, many of the properties of which it is wholly impossible to state in terms of the relatively simple physiological mechanisms out of whose combination it has developed.

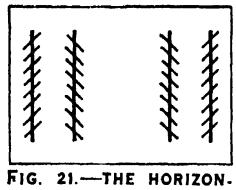

FIG. 21.—THE HORIZONURE

7. ERRORS OF REFRACTION AND ACCOMMODATION

The following is a classification of errors of refraction from the medical point of view (*see* Eye):

a. Errors of refraction—
Hypermetropia, Myopia, Astigmatism, Anisometropia, Aphakia.
b. Failure of accommodation—
Presbyopia,
Paralysis of Accommodation due to
Drugs (Atropine and its derivatives);
Toxic Diseases—
Diphtheria, Encephalitis, Lethargica, etc.

The eye as an optical apparatus is very much like a camera obscura, consisting of a lens system and a sensitive screen, the retina, upon which an inverted image of an object may be formed.

The length of the eye is roughly 23 mm., which means that the retina is placed about 23 mm. behind the anterior surface of the cornea. Parallel rays entering the eye come to a focus upon the retina, so that the eye, at rest, is focused for infinity, and the retina is placed at the principal focus of the lens system of the eye: thus an object placed at infinity will cause an image to be formed upon the retina.

In optics the path of rays is reversible, so that, in the case of the eye, an object at infinity will give an image upon the retina, and an object upon the retina will give an image at infinity. These two points are called conjugate foci, and infinity is spoken of as the punctum remotum of the eye. Such an eye is called an *emmetropic* eye.

Not all eyes are exactly 23 mm. in length, but in all eyes the power of the refractive apparatus is roughly the same. The result is that if the eye be shorter than usual the image will fall behind the retina, and a condition of *hypermetropia* is said to exist, and when the eye exceeds 23 mm. in length, the image is formed in front of the retina and a condition of *myopia* is the result.

1. **Hypermetropia (Hyperopia, Far Sight).**—This is the form of ametropia in which, with the accommodation at rest, parallel rays come to a focus behind the retina. The result is that the retina cuts the point of rays, before the focus is reached, and as a result an indistinct image is formed.

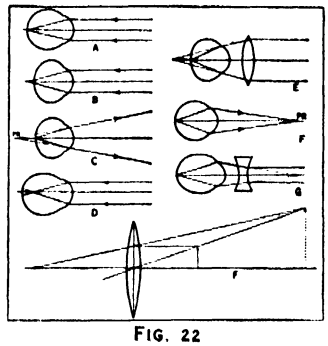

FIG. 22

A. Emmetropic eye, with parallel rays coming to a focus upon the retina. B. Hypermetropic eye showing how parallel rays form a circle of diffusion upon the retina. C. Position of the punctum remotum in Hypermetropia. D Myopic eye, showing how parallel rays form a circle of diffusion upon the retina. E. A convex lens causing parallel rays to come to a focus upon the retina. F. Position of punctum remotum of the Myopic eye. G. Concave lens enabling parallel rays to focus upon the retina. H. Simple lens system comparable to the arrangement of refracting system and retina of hypermetropia. F. Position of punctum remotum

In emmetropia the retina is placed at the principal focus of the lens system of the eye, in hypermetropia it is placed nearer to the lens system than its principal focus. Compare this with the formation of an image by a simple convex lens. If an object be placed at the principal focus of the lens an image is formed at infinity, a condition comparable to emmetropia, but if the object is placed nearer to the lens than its principal focus the rays will be divergent as they leave the lens and so will never come to a focus to form an image: they will have been made to appear to diverge from a second point on the same side of the lens as the object so that there will be formed a virtual image, a condition comparable to the one of a convex lens as a single magnifying glass. This means that rays proceeding from an object upon the retina of a hypermetropic eye will leave the eye in a divergent direction so that they appear to originate at a point behind the eye, the conjugate focus of the retina, the punctum remotum, whose distance behind the eye will vary inversely with the length of the eye. So that rays may come to a focus upon the retina of the eye, they must diverge from or converge towards the punctum remotum of the eye and it will be seen that only convergent rays can come to a focus upon the retina of the hypermetropic eye. Convergent rays do not occur in nature, so that one who suffers from hypermetropia is unable to receive a sharp image of any object in space when the eye is at rest.

2. **The Correction and Measure for Hypermetropia.**—A convex lens has the power of rendering parallel rays convergent so that an image is formed at the principal focus (*q.v.*). In ophthalmology lenses are considered, not in relation to the curvature of their surface, but to their focal length. A lens which causes parallel rays to come to a focus at a distance of one metre, is said to have a focal power of one dioptre, and this is the standard adopted. Thus a lens which has a focal power of two dioptres has twice the power of a one dioptre lens, and so will have a focal length of half a metre. (*See* OPHTHALMOLOGY.)

To relieve the condition of hypermetropia parallel rays before they reach the eye must be rendered convergent so that they will come to a focus at the punctum remotum of the eye. If therefore a convex lens is placed close to the cornea so that its principal focus coincides with the punctum remotum of the eye, then parallel rays will come to a focus upon the retina. The dioptric value of the lens that fulfills this condition is the measure of the hypermetropia and an eye is spoken of as having 2 or 3 dioptres of hypermetropia as the case may be.

3. **Visual Disturbances Produced by Hypermetropia.**—From an earlier paragraph it might be inferred that the hypermetropic individual was only able to see distinctly with a correcting lens. This of course is contrary to usual experience, and it will be noted that only the condition of the eye at rest was referred to—what is known as the *static* refraction of the eye.

The eye possesses the power of altering its focus so that an emmetropic eye can see perfectly well in the distance when in a condition of static refraction, and may also see small objects quite near at hand by making a suitable effort. This is known as the *accommodation of the eye for distance.* This is brought about by an alteration in the crystalline lens and is equivalent to the addition of a convex to the eye: consequently the eye has the power of correcting hypermetropia by an effort of accommodation. Thus it is that the inconveniences of hypermetropia are not only dependent upon the inherent defect of its optical apparatus but also upon the extra strain placed upon the muscular effort needed to focus the eye.

If the amount of hypermetropia is very high, it will be found that both distant and near vision is imperfect, and often the possessor suffers little other disability because any effort to correct the error is of little use and so no attempt is made. In the lesser degrees, an effort is made, often with success, so as to give quite acute distant and near vision. In youth, when the power of accommodation is ample (*vide* Presbyopia) the complaint is not so much of indistinct vision as of pain in the forehead and eye, due to the excessive strain upon the function of accommodation, and often it is only upon enquiry that the information is obtained that print held at the ordinary reading distance occasionally blurs, especially as the day progresses, and the muscle of accommodation tires.

These symptoms are collected together under the name of *accommodative asthenopia.*

4. **The Treatment of Hypermetropia.**—This consists essentially of ordering suitable spectacles with convex lenses which are the measure of the defect. It may be found to be the case that it is necessary to paralyse the accommodation with either atropine or homatropine, so that the whole of the hypermetropia may be discovered. This is often necessary because the sufferer has become so accustomed to a continuous effort for accommodation that he is unable to relax this effort, even when convex lenses are placed before the eyes. As a result glasses that correct only a part of the hypermetropia may be prescribed. In children, glasses are often prescribed for constant use, whereas in adults, provided the distant vision is good with the naked eye, the spectacles are only needed for near work.

5. **Myopia.**—This is the form of ametropia in which with the accommodation at rest, parallel rays come to a focus in front of the retina. The result is that the retina cuts the parallel rays before a focus is reached and so an indistinct image is formed.

Compare this with the formation of an image by a simple convex lens. Myopia is similar to the arrangement of an object placed further from the lens than its principal focus (but less than twice that distance). The image in this circumstance is formed upon the other side of the lens, inverted and real, nearer to the lens than infinity. Thus an object upon the retina of a myopic eye gives rise to a real inverted image in front of the eye at a distance less than infinity: this point is the punctum remotum of the myopic eye and is conjugate to the retina. It is seen that only divergent rays can come to a focus upon the retina and that with the accommodation at rest, only objects placed at the punctum remotum can be seen clearly.

6. **The Correction and Measure of Myopia.**—A concave lens has the power of rendering parallel rays divergent so that a virtual image is formed on the principal focus. In dealing with the correction for Hypermetropia the measure dioptre has been explained.

To relieve the condition of myopia, parallel rays before they reach the eye must be rendered divergent so that they appear to come from the punctum remotum of the eye. If therefore a convex lens is placed close to the cornea so that its principal focus coincides with the punctum remotum of the eye, the parallel rays will come to a focus upon the retina, and the lens is the measure in dioptres of the myopia.

7. **Visual Disturbances Produced by Myopia.**—Hypermetropia need not necessarily reduce the acuity for distant vision,

but the smallest amount of myopia will always cause a reduction. The defect is revealed therefore by an inability to see distant objects, and in children a difficulty in seeing writing upon the black-board. There is however no difficulty with near vision provided the object is held at the punctum remotum of the eye.

In low degrees the only disability will be a reduction of distant visual acuity, but in the high degrees there will be difficulty in maintaining clear vision at close range owing to the amount of convergence that must be used to obtain simultaneous vision with each eye. In the high degrees of myopia, vision after correction with a suitable glass is often lower than standard, owing to the stretching of the retina which frequently leads to various diseased conditions causing serious loss of sight.

8. **Development and Course of Myopia.**—Myopia is almost exclusively an acquired condition, in contrast to hypermetropia, which is congenital. The eye has usually fully developed by the tenth year when it should be practically emmetropic. It is between ten and twelve years that so many cases of myopia arise. The proportion of patients that are myopic increases gradually until the twentieth year, by which time above 20 per cent. of the population are myopic, a figure that remains constant for all ages, so that at the seventy-fifth year the number of patients that suffer from myopia is still 20 per cent.

In the towns, myopia is more common than in the country, and the prevalence of myopia among those who use their eyes for near objects (scholars, embroiderers, tailors, compositors) lends weight to the view that myopia is due to the strain imposed upon the eyes by such occupations. It is however doubtful if the use of the eyes for near work is the cause of myopia, although the eyes that are already myopic are affected adversely by occupations needing the use of the eyes at a close range.

9. **Treatment of Myopia.**—This consists essentially in ordering suitable spectacles with concave lenses which are the measure of the defect. Care must be exercised lest a lens be prescribed of higher dioptric value than that which corrects the myopia; consequently the weakest lenses that give the highest visual acuity are given to the patient, and he is encouraged to use them constantly, as the correction that renders the eye as physiologically perfect as is possible is the chief means available for holding in check the increase of myopia.

10. **Astigmatism.**—Simple hypermetropia and myopia are due, as we have seen, to a disproportion between the dioptric value of the refracting media and the length of the eye, and since the dioptric value of the eye in either state is the same, these errors are due to an undue shortness or length of the eye.

An error may presumably be due to some fault in the refracting media, either abnormal curvative or index of refraction, and there is one common error of refraction due to a curvature defect called astigmatism. In this condition the radius of curvature of the cornea is not the same in all meridians and consequently rays of light entering the eye in one meridian will not come to a focus at the same plane as rays entering in some other meridian, and the result is defective vision owing to the blurred image formed upon the retina. This error differs essentially from simple hypermetropia or myopia in which the refracting surfaces focus rays of light equally in all meridians, constituting spherical errors.

11. **Visual Disturbances Produced by Astigmatism.**—In all forms of astigmatism the visual acuity is reduced, and when associated with a spherical error the reduction is greater. When testing the visual acuity by test types certain letters are confused, namely, those whose constituent parts are formed of lines inclined to one another such as Z, X, M, N; and if a system of lines radiating from a common centre be used as a test object, certain of the lines will appear more sharply in focus than others. It will be noticed that the most sharply defined line and the least sharply defined are at right angles one to the other. This form of astigmatism, which is called *regular astigmatism*, is the only form which may be satisfactorily corrected by lenses; astigmatism produced by disease of the cornea is always *irregular* and can only be partially corrected by spectacles.

12. **The Correction and Measure of Astigmatism.**—This consists essentially in placing before the eye another astigmatic refracting medium which if properly chosen and adjusted will neutralize the distortion produced by the astigmatic surface of the eye. Such a correcting glass contains a cylinder combined or not with a spherical lens. The measure of the astigmatism is the difference between the dioptric value of the lens which corrects the axis of least and that which corrects the axis of greatest ametropia; thus if a+2 D spherical lens corrects the axis of least and a+4 D spherical lens corrects the axis of greatest ametropia, the eye is said to suffer from 2 D of astigmatism.

13. **Anisometropia.**—This is the condition in which there is a marked difference in the refraction of the two eyes, although theoretically the term should apply to the slightest difference. It has been shown that we cannot, by a voluntary effort, overcome a difference in refraction between the two eyes of more than ·12 D. When two eyes, with a similar static refraction, are accommodated for an object held mid-way between the two eyes, no difference in accommodation is necessary in the two eyes to produce equally sharp images upon the retinae, but when the object is held to one side at a near range, an equal amount of accommodation in each eye will not produce equally sharp images in the two eyes. It will thus be seen that in a given case of anisometropia an object held in the mid line between the two eyes will not produce sharp images in each eye when equal degrees of accommodation are exerted in the two eyes.

It is found that the eye which is properly focused is the one which requires the less accommodative effort for the distance at which the object is held, so that when one eye is myopic, and the other emmetropic, the myopic eye is correctly focused and so on.

14. **Aphakia.**—This is an error of refraction produced by absence of the crystalline lens from its usual position behind the pupil, and it is the condition regularly produced by the operation for removal of a cataract. The result is that the eye has lost one of its most important refracting media and so is rendered highly hypermetropic.

The condition is corrected by the use of a high power convex lens, often as high as +11 or 12 D.

Owing to the absence of the lens the eye is deprived of all power of focusing for distances; it has lost its function of accommodation.

15. **Presbyopia.**—It is a matter of common experience that an eye is capable of focusing itself for a variety of distances from infinity to within a short distance of the eye (at least in young individuals) and this function is spoken of as that of *accommodation for distances*.

This power of accommodation varies with age and is found to diminish as the individual grows older, starting in quite early life. Thus at 10 years of age, 14 D can be added to the intraocular lens by an extreme effort of accommodation whereas by the age of 20 years, this is reduced to 10 D, by 30 years to 7 D, and by 40 years to 4·5 D. By 45 years of age, the amount that can be added is only 3·5 D, which means that in the emmetropic individual clear vision for small objects is only possible at 28 cm. When in these circumstances the nearest point for which the eye can accommodate has receded to 28 cm., the eye is said to suffer from presbyopia.

We usually hold small objects such as printed letters at 25 cm., and books are printed with letters of such a size that they are capable of being read comfortably at about 25 cm.; the consequence is that the presbyopic individual has to hold his book at 28 cm. which makes reading difficult, and in the evening when he is tired, and the illumination is less good, reading becomes very difficult. As this change is progressive, it is found that all power of accommodation for practical purposes has been lost by 70 years of age. To read comfortably at 25 cm. it is necessary to possess not only 4 D of accommodation, but a minimum of reserve of 0·5 D, and we therefore aim to give the sufferer a lens of such a strength that together with his own power of accommodation the total amounts to 4·5 D. Thus in an emmetropic individual of 45, with 3·5 D of accommodation, the prescription of a spectacle containing a+1 D lens will bring the total up to 4·5 D, and the nearest point for which he can focus to 22 cm. (C. Go.)

VISIT AND SEARCH, a term for the procedure adopted by a belligerent warship to ascertain whether a vessel is enemy or neutral, and if neutral whether it is carrying contraband. If upon visitation the vessel proves to be the former she may be seized and sent into a port of the belligerent; if the latter, the visiting officer first examines the ship's papers and if these upon examination prove unsatisfactory, he may then proceed to search both vessel and cargo. If the vessel has been guilty of unneutral conduct, if bound for a blockaded port, or if the cargo is contraband, the neutral vessel may also be seized and sent into a port of the belligerent; if innocent she must be released, the fact of visitation being previously entered in her log book. If the court is satisfied that the capture has been made without probable cause, the captor is held responsible in damages and costs, and even if there was probable cause he may be held liable for any loss or damage due to his default or that of his subordinates. Owing to the size of modern vessels and the danger from submarine attacks, it is often impracticable to carry out search at sea and even visit is not always attempted. In the World War British and Allied commanders directed their captures to proceed to designated ports. If resistance to visit and search is made by an enemy or neutral vessel, it may be attacked and even destroyed by the belligerent. By Art. 63 of the Declaration of London "Forcible resistance to the legitimate exercise of the right of stoppage, search and capture involves in all cases the condemnation of the vessel. The cargo is liable to the same treatment as the cargo of an enemy vessel. Goods belonging to the master or owner of the vessel are treated as enemy goods." It has been suggested that passports or certificates issued by the authorities of the neutral vessel's State, certifying its nationality and destination, and containing a specification of the cargo would "afford such reasonable guarantees as to cause the exercise of the belligerent right of search to sink into a much-desired desuetude." (*See* NEUTRALITY.) (H. H. L. B.)

The instruction for the U.S. navy issued in June 1917, stated:—

"42. The belligerent right of visit and search may be exercised outside of neutral jurisdiction upon private vessels, unless under convoy, after the beginning of war in order to determine their nationality, the port of destination and departure, the character of their cargo, the nature of their employment, or other facts which bear on their relation to the war."

Visit and search may be carried out on the high seas or in belligerent waters. Before proceeding to visit and search the vessel should be summoned to stop and to lie to. When the vessel has come to, an officer and two unarmed men usually constitute the visiting party and the instructions of many States prescribe that the visit and search shall be carried out with courtesy. The ship's papers are first examined and if suspicious or defective the vessel may be seized or further investigation may be made. If a vessel does not come to when summoned, force may be used. Some States exempt from visit and search neutral vessels under neutral convoy. The right of visit and search continues during the whole period of the war even during an armistice unless otherwise specifically provided. (*See* NEUTRALITY.) (G. G. W.)

VISITATION, an act of visiting, a formal visit; also, from Biblical phraseology, an act of divine retributive justice.

There are three classes of official visitations: ecclesiastical, charitable and heraldic. Ecclesiastical visitations, originally the periodical journeys of personal inspections to ascertain the temporal and spiritual condition of each parish, form part of the functions of an archbishop, bishop, or archdeacon.

In Great Britain, all charitable corporations are at law subject to visitation. If no visitor has been appointed by the founder, the king or his representative is the visitor of all lay, and the Church of all ecclesiastical charitable corporations. Under the Charitable Trust Acts and the Endowed Schools Acts, the board of charity commissioners and the board of education have certain visitorial powers.

Heraldic visitations (which ceased about 1686) were perambulations made by a king-at-arms, or other heraldic official with a commission under the Great Seal, to examine into pedigrees and claims to bear arms. The results of these visitations were entered in "visitation books"; their admissibility as judicial evidence, however, is questioned, on the ground that they merely contain statements obtained from the families to whom they refer (*cf.* D'Arcy de Knayth case, 1901).

VISITING CARDS. The use of cards of identification for social purposes is generally supposed to have had its origin at the court of Louis XIV. of France. But in a ruder form, this mark of intercourse dates from much earlier times; the Chinese in bygone ages employed such mediums of communication on calling at the houses of absent friends. They were used in Germany as early as the 16th century. Strips of paper were first employed for the purpose; but gradually they attained a more elaborate finish. Ladies seem to have been the pioneers in this direction, and to have embellished their cards with hand drawings. Under Louis XV. visiting cards were furnished with delicate engravings, showing some fanciful landscape, or a view of the town or place where the person resided.

VISOKO, a town of Bosnia, Yugoslavia. Pop. (1921) 4,062. It is connected by rail with Sarajevo, and has a brisk trade in leather, carpets, sugar beet and tobacco. Between the 16th and 17th centuries it was second only to Jajce as a stronghold of the Bosnian rulers.

VISTULA, a river of Europe, which rising in Czechoslovakia, runs through Poland, along the frontier of East Prussia, and debouches through the territory of the Free City of Danzig. Its situation fits it to be a waterway of the first importance, although it is liable to floods and frozen over for three months in the year. It must be made navigable for river-craft at their full capacity during a sufficiently long period of the year; and must be open to international shipping on a footing of equality. At present it is navigable up to Przemsza, but there is no regular traffic above Warsaw, although it is largely used for timber-floating.

Before the World War conservancy works had only been carried out on the German part of the river, 222 km. in length; spur and longitudinal dykes were built to maintain the water level, thereby facilitating the flow of water at flood-time and also improving navigability. Since the War Poland has been too occupied to carry out improvement works, or even much in the way of upkeep. Traffic has greatly decreased.

Under Article 18 of the Treaty concluded at Versailles on June 28, 1919, between Poland and the Allied and Associated Powers (the so-called "Minorities Treaty") Poland undertook to apply to the river system of the Vistula (including the Bug and the Narew), pending the conclusion of a general convention on the international régime of waterways, the régime set out in Articles 332–337 of the Treaty of Versailles, that is to say, the régime applicable to International Waterways.

Serious differences of opinion arose as to the interpretation of the legal status of the Vistula. It has been asserted that Article 18 should be held to provide for the possibility of the Vistula being subject to the régime of the Barcelona Convention (*see* INLAND WATER TRANSPORT), once that Convention has been ratified by Poland, and should the Vistula come under the general definition contained in the said Convention. But those who urge this theory do not consider that the Vistula comes under this definition, since the criterion therein accepted is that the part of the river which is naturally navigable should traverse or separate several States. As the right bank of the Vistula in Eastern Prussia has been given to Poland to a depth of 50 metres in land, Germany is not a riparian State; and the Free City of Danzig should not in law be considered as a State.

On the other hand it has been urged that the words "pending the conclusion" mean that the régime of Articles 332 to 337 will be automatically superseded by the régime of the General Convention as soon as the latter has been concluded, and this regardless of the fact whether the Vistula will, or will not, eventually come under whatever general definition is established by the General Convention given in the said Convention. Those who put forward this second argument assert that the Minorities Treaty certainly did not contemplate a temporary international régime for the Vistula, since such an arrangement would have been contrary to all ideas of an international régime. They maintain that, if it is to the interest of international shipping to have certain guaran-

tees of freedom of navigation and equality of treatment, that interest does not cease with the conclusion of an international convention. Further, they are of opinion that the Vistula is included in the category of navigable waterways referred to in paragraph 2 of Article 1 of the Barcelona Statute. A solution to this acute legal controversy will hardly be found unless the dispute becomes an inter-State one and comes before the Permanent Court of International Justice.

See *Vistula: Traité des Minorités entre les principales Puissances alliées et associées et la Pologne du 28 juin, 1919* (Great Britain, Treaty Series, 1919, No. 8). (J. M. F. R.)

VISTULA-SAN, BATTLES OF THE. The middle of Sept. 1914 marked a distinct stage in the World War, both in the western and eastern theatres. The victories over Samsonov and Rennenkampf in East Prussia (*see* MASURIA, BATTLES IN) had rendered that province secure from invasion for some time, but these battle-fields were too far distant from Galicia for success to bring relief to the Austrians. Direct assistance was required. Accordingly, 5½ corps, the bulk of the forces in East Prussia, were transferred by rail to the Cracow-Częstochowa area in the latter half of September.

This move required some 750 trains and was completed between the night of Sept. 16–17, when the troops began to entrain about Königsberg and Lötzen, and Sept. 28, when they were deployed on the frontier of south Poland ready to advance. They were formed into the 9th Army under Hindenburg, with Ludendorff as his chief of staff. The 8th Army was left in East Prussia with much reduced forces. The plan was for Hindenburg's army to advance against the stretch of the Vistula between Zawichost and Deblin (Iwangórod), with the intention of turning the northern flank of the main Russian forces, which were at this time concentrated in Eastern Galicia. A part of the Austrian 1st Army (Dankl) was to advance on the north bank of the Vistula to the right of the Germans, while the main Austrian forces moved to the attack south of the Vistula, the 4th Army (Grand Duke Josef Ferdinand) and 3rd Army (Boroevich) towards the lower San and Przemyśl, while the 2nd Army (Bohm-Ermolli) from the Carpathians moved in the direction of Chyrow and Sambor, south of Przemyśl.

Russian Problems.—On the Russian side, at the same period of mid-September, the most urgent tasks of the commander-in-chief were to reconstitute his north-western front, shattered by the defeats of the 1st and 2nd Armies in East Prussia, and to build up a central force in Poland about Warsaw. First-line troops from Siberia and Turkistan, which had not been available for the opening engagements, had now arrived, and a large number of additional reserve divisions were in the field. The 9th Army, which was originally to have formed the nucleus of the central force, had been despatched south in the early days of September to the rescue of the hard-pressed 4th Army (*see* LEMBERG, BATTLES OF), and was now with four other Russian armies (4th, 5th, 3rd, 8th) in eastern Galicia, on the line of the San and Dniester. The supply of these five armies, comprising some 18 or 19 corps, crowded on a comparatively narrow front, was extremely difficult. As early as Sept. 22 three corps were ordered to move north to relieve the congestion. Shortly afterwards, information was received of the enemy concentration and advance, and a rapid change in the disposition of the armies became necessary to meet this threat. The question arose whether a line could be built up in Poland west of the Vistula with sufficient speed to render it safe to accept battle in advance of the river, or whether the change of front should be carried out behind the shelter of the river barrier. The safer course was chosen; and the principal masses moved to the north in rear of the Vistula, only cavalry forces being left to oppose the hostile advance in trans-Vistula Poland. The decision was undoubtedly wise, but it involved certain grave disadvantages. It meant the surrender of the whole of south-west Poland to the enemy, severe hardships to the troops in traversing the almost roadless region south of Lublin, and the eventual forcing of passages over the Vistula. Three armies, the 4th, 9th and 5th, moved north, while the 3rd Army took over the line of the San. The great wheel was completed by the third week in October, by which time the 5th, 4th and 9th Armies, in that order from north to south, lined the Vistula from about Gura Kalvarya (south of Warsaw) to Zawichost. Meanwhile a new 2nd Army had been formed round Warsaw.

Austro-German Offensive Fails.—The Austro-German advance, which began at the end of September, met only slight opposition till the lines of the Vistula and the San were reached. During the advance, however, the regrouping of the Russian forces became evident and showed that the original German plan was no longer applicable. The main weight of the offensive of Hindenburg's army was therefore shifted northwards against Warsaw, the whole of the Austrian 1st Army being moved to the left bank of the Vistula and extended from Sandomierz to below Deblin. By Oct. 12 fighting was general on the whole front. Hindenburg's army was within a few miles of Warsaw, but had greatly superior Russian forces against it; while all along the river from Warsaw to Zawichost the Russian counter-offensive was battling for passages to the left bank. South of the Vistula, the Austrian 4th and 3rd Armies had driven in light Russian forces and reached the line of the San by Oct. 10, causing Radko-Dimitriev's 3rd Army to raise the siege of Przemyśl. But they could make no headway in their efforts to force the line of the San. Nor did the 2nd Army, advancing from the Carpathians towards Sambor and Chyrow, meet with any greater success.

By Oct. 17 it was clear to Hindenburg that his offensive could not succeed. North of the Vistula, the German 9th Army and Austrian 1st Army were now assailed from Warsaw, from Deblin and from Zawichost by four Russian armies; while south of the Vistula the three Austrian armies could make no progress against the Russian 3rd and 8th Armies. The Austro-German attacks were, however, continued till the 21st. They were succeeded by violent Russian counter-attacks, which lasted till the 27th. Hindenburg then broke off the battle and led his 9th Army rapidly back to the frontier, destroying all communications as he retired. Dankl's Austrian 1st Army withdrew in more leisurely fashion. Between Oct. 31 and Nov. 2 it held the Russian pursuit at arm's length in the Kielce-Opatów region; and then retired behind the Nida. On the San, fighting continued till the end of October, without marked advantage to either side. But early in November, the Austrian armies broke off the battle and withdrew.

Hindenburg's first invasion of Poland had only relieved the pressure on Austria for a time. Its failure left Germany's ally still further exhausted. It was a bold move, typical of Ludendorff's strategy. But he seems to have under-rated the Russian leadership and to have over-rated the fighting powers of the Austrians.

VISUAL EDUCATION, a term used in the United States to designate those forms of instruction in which use is made of prepared visual aids, such as models, maps and charts, mounted pictures, lantern slides, films for the projection of still pictures, stereographs and motion picture films. Visual education is a method of instruction which may be used at all ages or levels of schooling and is equally appropriate in teaching geography, history, nature study, physics, physiology, agriculture, astronomy and several other subjects. The most important of the visual aids are lantern slides, stereographs, films for the projection of still pictures and motion picture films.

Motion pictures have been tried in schools ever since they came into wide use for entertainment, but their full possibilities have not been realized. Efforts are being made to facilitate their use by producing narrow width and hence cheaper films, printed on non-inflammable stock, and by manufacturing simpler and more easily handled machines. Efforts are also being made to supply, on a larger scale, informational films, made to fit into the courses of study of the schools.

Organizations for the Promotion of Visual Education.—The first national organization for the promotion of visual education was the National Academy of Visual Instruction. This

society consisted chiefly of members of extension divisions of State universities. The second was the Visual Instruction Association of America, organized not only to hold meetings and disseminate information but also to produce motion picture films. In 1923, the department of visual instruction of the National Education Association was formed.

Psychology of Visual Education.—The spread of visual education, as is often the case with new movements, has been accompanied by extravagant claims on the part of some of its advocates and by a certain amount of loose thinking concerning the psychological basis for the use of visual methods. Visual education is frequently advocated on the supposed ground that the sense of sight is a better avenue for the acquirement of experience than are the other senses, particularly hearing. Psychological studies consisting of careful experimental comparisons have led to sounder theory and a more moderate estimate of the essential place and value of the visual method.

The essential contrast is not between the senses of vision and hearing. It is rather between the direct experience, which consists of the perception of material objects on the one hand, and the indirect experience, which consists of abstract or generalized thought on the other hand. Direct perception is carried on by means of the various senses—not vision alone—while thought is carried on largely by means of language. The contrast, then, is between sense perception and language. But, properly regarded, the two are not opposed to one another. They rather supplement one another. Sense perception or concrete experience alone has little meaning or significance, while an over-emphasis on verbalism without sufficient concrete experience leads to error and confusion of thought. Doubtless education has tended too much to verbalism and needs from time to time to be brought back to a closer contact with the world of physical objects.

The sense of vision is a particularly valuable source of educative experience. First, besides furnishing distinctive qualities of its own it serves to represent or suggest many qualities which are given directly by other senses, such as hardness, smoothness and weight. Second, it is especially adapted to exhibit relationships of a very definite and exact nature. The chief of these is space. On the other hand, hearing yields the sensations which are peculiarly adapted to serve as the means to the development of language. A well rounded education employs each for its proper purpose.

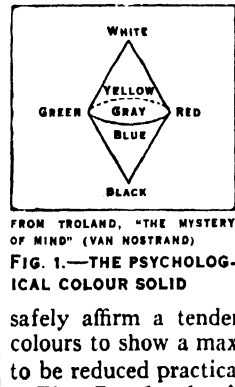
(F. N. F.)

VISUAL SENSATION. The problem of visual sensation has to do with the dependence of visual experience upon certain features of the physiological visual process which lie on the so-called "afferent" side of the nervous arc. These features include the elementary properties of (1) the stimulus (light or electromagnetic radiation having appropriate wave-lengths), (2) the retinal excitation, (3) the conduction along the optic nerves, and (4) certain aspects of cerebral activity. The boundary line between sensation and perception is somewhat vague. From the classical standpoint, perception is concerned with the manner in which various constituent factors are put together to form distinct psychical patterns, these patterns being regarded in general as representations of objects which are actually before the eyes. Sensation, on the other hand, is considered as furnishing the materials for such perceptual syntheses, and as being concerned more with the stimulus energy and the sense organ response than with either the brain processes or the object. However, modern studies of the manner of dependence of experience upon cerebral conditions have made rather free use of the concept of sensation.



If we regard visual sensation, from the introspective standpoint, as a subjective material, out of which complex visual perceptions are compounded, the substance of such sensation appears to be reducible to two kinds, *colour* and *depth*. Colour characterizes object surfaces, while depth constitutes the spatial medium which intervenes between these surfaces and the empirical eye. These elementary factors can be arranged, at various times, so as to form an indefinitely large number of characteristic perceptual patterns, to constitute the phenomena of visual experience.

Introspective Properties of Colour.—The concept of colour is here used broadly to include all elementary visual qualities, whether they belong to the chromatic or to the achromatic classification. The latter comprises a scale of greys, extending between black and white, while the former includes a cycle of hues at various saturation values. The outstanding or *psychologically primary hues*, are red, yellow, green and blue, but these have many intermediates, of which the typical ones are orange, yellow-green, blue-green and purple. The total number of possible achromatic colours has been estimated at between 600 and 800, of discriminable hues at about 150, and of different saturation values of each hue, at approximately 20. According to Titchener, the total number of discriminable colours is about 35,000, but this number must vary widely with conditions.

The *achromatic colours*, or greys, can be arranged in linear order, so as to form a system which has only a single dimension. This dimension has been variously designated as one of brightness, luminosity, value, or tint, but the term *brilliance* is to be preferred because of its freedom from disturbing connotations. Brilliance is at a minimum for an ideal black and is at a maximum for an ideal white. Intervening greys can be designated numerically by counting the number of just noticeably different achromatic colours which separate them from the ideal black. The chromatic colours may also differ from one another in brilliance, although if they differ in this only they will have identical *chromas*.

If we consider all *chromatic colours* which are possible of the same brilliance, we find that they can be ordered to form a surface, or a two-dimensional figure. This figure will automatically include the single achromatic colour which is of the given brilliance. Any colour within this surface can evidently be specified in terms of values along each of the two dimensions. The axes for the latter are best chosen in accordance with a system of polar coördinates, with its centre at the grey point. Radial values, measured in just noticeable steps from the centre, then represent the *saturations* of the colours, whereas circumferential values designate the *hues*.

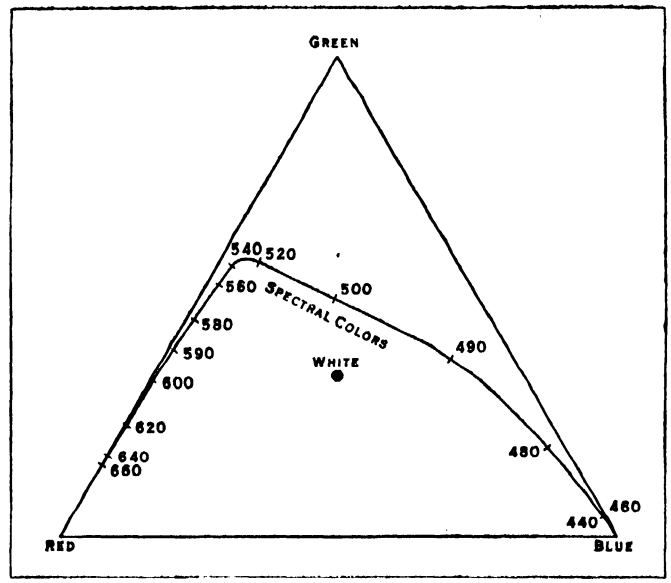
These two systems, the chromatic and the achromatic, can obviously be combined to form a three-dimensional figure which embraces, simultaneously, the properties of brilliance, saturation and hue. The resulting scheme, as diagrammed in fig. 1, provides locations for all conceivable colours, and thus enables us to specify any colour numerically in terms of three determinants or *attributes*. Chromatic colours exist, or are conceivable, at all levels of brilliance, so that the figure becomes a *psychological colour solid*. The exact boundaries of this solid cannot be specified at the present time, although we may safely affirm a tendency for the number of possible chromatic colours to show a maximum in the middle range of brilliance, and to be reduced practically to zero at the ideal black and white.

FROM TROLAND, "THE MYSTERY OF MIND" (VAN NOSTRAND)

FIG. 1.—THE PSYCHOLOGICAL COLOUR SOLID

The Psychophysiology of Colour.—Experimental studies of visual sensation have been concerned, for the most part, with the laws which connect brilliance, saturation and hue with features of the stimulus and sense organ process. The electromagnetic waves which constitute the stimulus impinge upon the corneas of the eyes, pass through the pupils, and are refracted by the various ocular media so as to form images upon the retinas. The elementary properties of the stimulus, from the physical standpoint, are its intensity and its relative wave-length composition. The latter can be subdivided into two features, such as dominant wave-length and purity. The simplest psychophysiological relations are found when homogeneous, or single wave, stimuli are

employed, and, in this case, the stimulus is specified by its wave-length and intensity.



It is found that all three attributes of colour depend upon each possible aspect of the stimulus. Beginning with the relationships of brilliance, we note, firstly, that at constant intensity this attribute varies with wave-length, in accordance with a function which is approximately of the probability integral type. This symmetrical, single maximum curve corresponds in general form with the so-called *visibility function*, although, strictly speaking, the latter represents the reciprocal intensities which are required at different wave-lengths, to yield equal brilliances, rather than delineating a direct psychophysical relationship. The visibility curve gives values by which *radiometric intensities* must be multiplied in order to secure the corresponding *photometric or light intensities*.

The position of the maximum of the function which connects brilliance with wave-length varies with the stimulus intensity and with the state of adaptation of the eye. At intensities corresponding to daylight, the maximum lies at about 554 mμ, but under twilight illumination it shifts to the neighbourhood of 511 mμ. The exact limits of the curve, which determine the extremes of the visible spectrum, naturally vary with the intensity level, but may be taken as 400 mμ and 760 mμ for daylight conditions, shifting with the maximum at lower intensities. The high intensity curve is characteristic of *photopic* (or cone) vision, while the low intensity one features *scotopic* (or rod) vision. The transition from the former to the latter is responsible for the Purkinje and other similar phenomena.

When a stimulus, of fixed wave-length composition, is varied in *intensity*, the brilliance is found to be a logarithmic function of the latter in the range of ordinary daylight intensities. At both higher and lower intensities, the brilliance changes less rapidly with respect to the intensity than is characteristic of the logarithmic section of the law. The total law may be designated as the Fechner function. In the logarithmic region, the just noticeable increment of intensity is approximately one one-hundredth part, depending upon conditions. The Fechner function is substantially independent of wave-length composition, if intensities are expressed in photometric terms, *i.e.*, if the physical intensities are multiplied by the corresponding visibility values. This is true for either homogeneous or heterogeneous stimuli, and in the latter case implies the principle that the light values of the components in a mixture add arithmetically.

Hue is determined primarily by the wave-length of the stimulus, when the latter is homogeneous, and by a quantitative balance between component wave-lengths and intensities, when it is heterogeneous. The hue changes progressively from one end of the visible spectrum to the other, although at a variable rate. Maximal rates of change of hue with respect to wave-length are found at 589 mμ, 507 mμ and 489·5 mμ, at each of which points a difference of 1 mμ is just noticeable. At the long-wave (red) end of the spectrum, there is no change of hue beyond about 700 mμ and there is only one just noticeable step between 700 mμ and 678 mμ. The psychologically primary hues, within the spectrum, are the yellow at 574·5 mμ, the green at 505·5 mμ and the blue at 478·5 mμ, the primary red requiring the admixture of a small quantity of short-wave radiation to the spectral rays between 700 mμ and the long-wave end. *Saturation* also varies with the wave-length of a homogeneous stimulus. It shows maxima at either end of the spectrum, with a minimum at about 575 mμ.

When the stimulus is heterogeneous, the hue and saturation are determined by rather complex principles, known as the *laws of colour-mixture*. The simplest case is that of two-component mixtures, involving pairs of homogeneous stimuli. If the wave-lengths and relative intensities are properly chosen, the result can be an achromatic colour or white, and in this case the stimuli (and the colours which they would separately evoke in isolation) are said to be *complementary*. If the wave-lengths of such complementary stimuli are held constant, and the intensities are varied from those required to yield white, a hue appears which is normal to the stimulus that is in excess, the saturation increasing with augmented unbalance. When the wave-lengths depart from those of complementary stimuli, the hue is intermediate, on the shortest arc of the hue cycle, between the hues normal to the two stimuli. The exact position of the hue on the arc is determined by the balance of intensities, naturally being near to that normal to the component which is intensively predominant, in proportion to the degree of predominance. The saturation is greater the more

FROM IVES, JOURNAL OF THE FRANKLIN INSTITUTE

FIG. 2.—THE COLOUR-MIXTURE TRIANGLE

the two stimuli depart from the complementary relationship, either as regards wave-lengths or intensities.

One of the most interesting cases of two-component mixture is that which involves the two extremes of the visible spectrum, yielding a series of *purples*, of which there are approximately 20, determined by the intensity ratios of the two components. The purples furnish the complementaries for colours or stimuli in the middle region of the spectrum, which find no homogeneous complementaries. The *three-component system*, thus generated, consisting of two extreme spectral stimuli and a mid-spectral stimulus, provides the most important of all cases of colour-mixture. It is found that variation of the intensity proportions of such stimuli, of fixed wave-lengths, permits the matching of all possible hues at a wide variety of saturations. This fact underlies the technique of three-colour reproduction and analysis. The laws which are involved are most simply represented by means of a colour-mixture triangle, such as is shown in fig. 2, where the three primary components are symbolized by the vertices of the equilateral figure.

The units of measurement in this triangle are so chosen that equal quantities of the three primaries yield white. The brilliance value of the blue or violet, thus required, is only about 1% of that of the red or green. The composition of any colour, in these terms, is found by locating it within the triangle and then dropping perpendiculars to each of the three sides. The length of the perpendicular opposite each primary indicates the proportion of the latter which is involved. The consequences of mixing any two colours can be determined, in this system, by drawing a straight line between the points which represent them, and then finding the centre of gravity of the line, treating the mixture intensities of the components as masses. Mixtures of any number of components can be handled in this way by successive combinations in pairs. Thus the triangle provides a universal method for dealing with the hue and saturation aspects of stimulus mixtures. The colours of the spectrum can be represented by a linear locus, and in order that this should fall inside rather than outside of the triangle, the latter is ordinarily reconstructed on the basis of an ideal, supersaturated, green primary.

Hue and saturation also vary with the absolute intensity of the stimulus. At both low and extremely high intensities there is a loss of saturation, which may be complete. There is also a change of hue, with increasing intensity, such that all colours,

except primary red and green, tend to become more yellowish or bluish, according as they lie on the yellow or the blue side of red or green, respectively. This is known as the Bezold-Brücke effect.

The relations of colour to retinal conditions can best be discussed in connection with spatial and temporal effects, although in only a few cases are we sure that such effects are retinally rather than cerebrally determined. Among *temporal phenomena*, we may mention those of *adaptation*, according to which continued exposure to any stimulus brings about changes in sensitivity which tend to neutralize the characteristic effect of the stimulus. Brilliance adaptation is apparently of two kinds, scotopic, involving a changing ratio between rod and cone vision, and photopic, depending upon changes within the cone system *per se*. The latter may be selective, as regards hue and saturation, reducing the latter and rendering the retinal system temporarily more sensitive to the complementary. Local alterations in sensitivity yield so-called negative and complementary after-images which can be used to demonstrate the rate at which recovery, or counter-adaptation takes place.

Other temporal effects include positive after-images, which appear to represent a continuation of the original excitation process for a short time after the removal of a stimulus; rhythmic alternations between positive and negative conditions, giving rise to such phenomena as Charpentier's bands and "recurrent vision"; and fusion, with intermittent stimuli presented at a sufficiently high rate, resting upon the so-called "persistence of vision."

Spatial dependencies are represented by the variation of hue and saturation with the position of the stimulus on the retina, the partial dependence of all of the colour attributes upon the size of the retinal image, and by the phenomena of contrast. In general, chromatic differentiation is at a maximum in the centre of the visual field and falls off towards the periphery in accordance with the same qualitative law which characterizes the Bezold-Brücke effect (*vide supra*). Brilliance shows a maximum in the centre of the field under photopic conditions, but a powerful minimum in the same position under scotopic adaptation. This is attributable to the absence of rods in the retinal centre or "fovea." Intensity thresholds for hue and brilliance are raised by decreasing the retinal size of the stimulus below a certain value, and at very small sizes the threshold is determined by the total energy striking the retina, regardless of its distribution between intensity and area. Contrast (*q.v.*) involves a change in the colour evoked by a given stimulus, because of the simultaneous action of another stimulus (or condition) on an adjoining visual area. The change is in the direction of the opposite of the contrast-inducing colour, being a darkening effect when the latter is bright, and a shift towards the complementary of the latter when it is of chromatic quality.

The most reliable conclusions regarding the dependency of visual experience upon the retinal mechanism are comprised in the so-called *duplicity theory*, according to which the two histologically differentiable types of receptors, the rods and the cones, have psychophysically distinct functions. The cones are supposed to have a relatively low degree of sensitivity and to subserve photopic or day vision, with chromatic discrimination. The rods, on the other hand, are characterized by a sensitivity which, at its maximum, is about 10,000 times as great as that of the cones, but by an absence of chromatic response. At high intensities of stimulation, they are practically eliminated by adaptation, but at low intensities, they entirely replace the cones. A multitude of spatial and temporal effects can be explained in terms of the differences in retinal distribution, spectral sensitivity and inertia between the rod and cone systems.

Depth.—The remaining factor in visual sensation, the depth impression, can be disposed of quite briefly, since it is customary to discuss its conditions in detail in connection with binocular visual perception. Depth elements seem introspectively to be all of the same kind, differing only in location within subjective visual space. They must be regarded as being determined directly by processes in the visual areas of the cerebral cortex, although their number and locations are regulated by a complex assembly of peripheral factors, the so-called primary and secondary criteria of depth. The most important among these factors consist in the disparations of the images of identical object points upon the two retinas. Hering treated such disparation as a sensory variable, having positive and negative values, corresponding with crossed and uncrossed relations of the corresponding lines of view, respectively. (*See* VISION.)

For a more detailed discussion of the problems of visual sensation, *see* J. H. Parson's *An Introduction to the Study of Colour Vision* (1924), or L. T. Troland's *The Principles of Psychophysiology*, vol. ii. chap. xiv. (1929). (L. T. T.)

VITALIANUS, bishop of Rome from 657 to 672, succeeded Eugenius I. and was followed by Adeodatus. In the monothelite controversy then raging he refrained from express condemnation of the *Typus* of Constans II. The chief episode in his pontificate was the visit of Constans to Rome; the pope received him "almost with religious honours," a deference which he requited by stripping all the brazen ornaments of the city—even to the tiles of the Pantheon—and sending them to Constantinople.

VITAL STATISTICS. This important subject is treated in a number of articles in this work, including POPULATION; CENSUS; BIRTH-RATE; DEATH-RATE; MARRIAGE-RATE; ILLEGITIMACY; SEX RATIO AT BIRTH AND DEATH; BIRTH CONTROL.

VITAMINS. Substances of unknown composition normally present in certain foodstuffs in minute quantities, the absence of which from the diet leads to well defined morbid states.

Accessory Factors and Growth.—The realization of the existence of vitamins grew gradually out of numerous attempts, made at various times, to feed animals on diets of known composition, as free as possible from all admixture (1881, Lunin). Much later it was found in England (1906–12, Hopkins) that under these conditions the animals lost weight and died but that if a relatively small amount of milk were included in the diet the animals flourished and increased in weight.

Simultaneously in Germany (1909–12, Stepp) somewhat similar observations were made and Stepp, like Hopkins and Lunin, concluded that something more was necessary for life than the amounts of pure carbohydrates, proteins and fats needed to satisfy the animals' requirements of energy and of material for new growth and the replacement of waste tissue. These facts were repeatedly confirmed in England and America, but the explanation was hard to find. A partial solution of the problem was afforded by the discovery in America (1913, McCollum and Davis) that on certain diets, themselves inadequate, growth could be induced in rats by the incorporation in the diet of the substances extracted by ether from yolk of egg or butter. On other diets however, this addition was found to be ineffective and a more complete comprehension of the conditions was only attained after the discovery (1915, McCollum and Davis) that not one but two "accessory" substances were required in addition to pure carbohydrates, proteins, fats and salts. For convenience these "accessory factors" were termed Fat-soluble A and Water-soluble B.

Deficiency Diseases.—Even before this advance of knowledge regarding the nutritional requirements of the growing animal similar ideas had been developed concerning the cause and prevention of certain diseases commonly attributed to a faulty diet. The incidence of beri-beri (*q.v.*) had already been traced to the exclusive use of a diet of polished rice, when it was found in Java (1897, Eijkman) that a similar disease manifested itself in fowls fed on this same diet. This important observation led to the detailed laboratory study of the disease, which was soon rewarded by the discovery that it followed on the absence from the bird's diet of a substance present on the "silverskin" or pericarp of the rice grain (which is removed in the process of milling and polishing) and could be cured when this, or an extract of it made with water, was administered. The experimental method thus established enabled the occurrence of this curative substance in other materials to be studied both qualitatively and quantitatively, as well as the effect upon it of varying conditions such as temperature and oxidation.

A precisely similar course of events took place with regard to

scurvy (*q.v.*). It was found in Norway (1907 Holst and Fröhlich) that scurvy could be induced in guinea-pigs by removing the greenstuff from the ordinary feed of grain and cabbage leaves and by giving a diet consisting of grain and water only. As in the case of beri-beri rapid progress followed experimental study of the disease and it was soon established that scurvy followed on the absence from the diet of a constituent present in fresh cabbage and in many fruit juices. By the use of guinea-pigs (and later of monkeys, which are also susceptible to the disease) it became possible to study the distribution of the preventive substance both qualitatively and quantitatively in food materials.

The closeness of the analogy between the "accessory factors" necessary for growth and the unknown substances which were essential for the cure or prevention of beri-beri and scurvy led to the inclusion of all these in one class, the vitamins (Funk 1912).

Although much has been added to our knowledge since the original classification of the vitamins as water-soluble and fat-soluble they may still be conveniently divided into these two groups, the former comprising vitamins B_1 and B_2, which have both been found to be present in the original "water-soluble B," together with vitamin C, the antiscorbutic vitamin, and the latter vitamins A and D, corresponding with the original "fat-soluble A," and vitamin E, the anti-sterility vitamin.

The Water-soluble Vitamins (Vitamins B_1, B_2 and C).—As has been seen from the foregoing, the water-soluble vitamin of McCollum and Davis was found to be effective in two different ways, the cure or prevention of polyneuritis in pigeons (and beri-beri in man) and the maintenance of growth and well being in rats. Both of these effects were produced by a long list of foodstuffs, the most efficacious being yeast, egg yolk, fish roe and the embryos of seeds.

It was at first thought that only one vitamin was concerned in these effects (1916 McCollum and Kennedy) but further investigation has gradually shown that in all these sources at least two vitamins are present, which can be distinguished both by their behaviour towards external factors (heat, etc.) and by the effect on the animal organism of their absence from the diet.

These are best termed vitamins B_1 and B_2, but at the date of writing unanimity on this question has not been attained and they are sometimes termed vitamins F and G (Sherman).

Vitamin B_1 (the Antineuritic Vitamin).—To the vitamin which guards against and cures beri-beri in man and polyneuritis in birds (1897 Eijkman) the name vitamin B_1 has been assigned. Although capable of withstanding the temperature of boiling water for one or two hours, it is readily inactivated when its solution is heated under pressure at 120° C, at which temperature vitamin B_2, which invariably accompanies it in natural sources, is scarcely affected.

Preparations have now been obtained which are highly active in the prevention and cure of polyneuritis in birds, a daily dose of 0·1–0·01 milligram being sufficient to keep a pigeon in good health. It has, however, no effect in curing or preventing the specific effects of absence of vitamin B_2 (*see* below) and does not by itself produce growth and well being in rats, the simultaneous presence of both water-soluble vitamin B_1 and B_2 being essential.

Vitamin B_2 (the Pellagra-preventing Vitamin).—When a rat is kept on a diet deficient only in this vitamin (and including a plentiful supply of vitamin B_1) it ceases to grow, but does not lose weight and may be maintained in this condition for several months. After a few weeks however inflamed patches appear on the skin and the rat suffers from a disease which is closely analogous to pellagra (*q.v.*) in man. This disease has long been known to be of dietetic origin and to be curable by a proper diet.

It is now thought (1927 Goldberg) that it is due to a lack of vitamin B_2 which is abundantly present in the materials found to have the greatest curative value, such as yeast, which is moreover effective after having been heated under pressure at 120° C, and lean meat (*see* table on page 221).

Little is so far known about the relative amounts of vitamins B_1 and B_2 in those materials in which they occur together. Judged by their effect on human pellagra (Goldberg), milk, eggs, wheat-germ and tomato juice all contain vitamin B_2 in smaller amount than lean meat, which is itself surpassed by yeast. Vegetables and fruits only contain very little and it is absent from oils and fats.

Vitamin C (the Antiscorbutic Vitamin).—The cure for scurvy was long recognised to be fresh food but quantitative experiments have shown that the vitamin occurs in very varying proportions in different food materials. Its richest sources are green leaves, especially of the cabbage tribe, the juice of *citrus* fruits (lemon, orange, and grape fruit), the tomato and certain roots such as the swede turnip. On the other hand meat and milk, the potato and many vegetables and fruits usually only contain the vitamin in comparatively small amount. It is absent from seeds but is produced on germination (1912, Fürst). Different animals vary greatly in their requirements of this vitamin. Thus guinea pigs (250–300 g.) need 100–150 c.c. of milk or 1·5 c.c. of orange juice or 1·5 grams of fresh cabbage per day, whilst monkeys, ten times their weight, require exactly the same ration; rats on the other hand require extremely little and can exist for long periods without it.

Of all the known vitamins, the antiscorbutic is the most readily inactivated by oxidation. This process is comparatively slow at air temperature but becomes very rapid when the temperature is raised. As a result of this a large proportion of the antiscorbutic potency of food materials is lost when they are cooked or dried. In the process of canning there is less exposure to air and some canned articles *e.g.* tomatoes, are still potent. Inactivation by oxidation is greatest in alkaline and least in acid solutions. In absence of air, materials containing the vitamin may be heated to a comparatively high temperature without serious loss, especially in acid solution. On storage after this treatment, however, the potency disappears much more rapidly than from the untreated material.

Fat-soluble Vitamins, A, D, and E.—After the discrimination of the water-soluble B and fat-soluble A vitamins (1915, McCollum and Davis) much attention was paid to the study of the latter. A very rich source of it was found to be cod-liver oil (1921, Zilva and Miura), whilst it occurred in much smaller proportion in the body fat of many mammals and fishes, in egg-yolk, milk and butter and cereal seed embryos.

In the absence of such food materials from their diet, young experimental animals ceased to grow, lost weight and finally died. Frequently a characteristic condition of the eye (xerophthalmia) developed before death. When this diet was supplemented by small quantities of material rich in the vitamin, growth was resumed, the eye symptoms cleared up and the animal became normal. It was also found (1915–1919 Mellanby) that some of the foodstuffs containing the fat-soluble vitamin A were effective in preventing the onset of rickets (*q.v.*) in puppies kept on certain special diets, and in curing the condition both in dogs and man. Nevertheless, certain discrepancies were soon observed, which led to the suggestion that two principles were concerned, and it was finally proved (1922 McCollum) that two fat-soluble vitamins exist, vitamin A which cures and prevents xerophthalmia, and vitamin D which cures and prevents rickets by promoting the proper calcification of bone. This conclusion has since received striking confirmation in many other ways. The simultaneous presence of both vitamins is essential for the normal growth and well being of the animal.

It has also been shown (1922, Evans and Scott) that a third fat-soluble vitamin exists, the presence of which in the diet is essential for the fertility of rats.

Vitamin A (the Anti-xerophthalmic Vitamin).—The richest natural sources of this vitamin are the liver fats of many mammals and fishes. In some of these (liver oils of salmon and halibut, cod-liver oil) it is accompanied by vitamin D but in others not (liver fat of sheep, calf and ox). The liver oils of salmon and halibut contain 100 times as much vitamin A as cod-liver oil and the liver fats of sheep, etc., ten times as much, whereas butter only contains about $\frac{1}{10}$ of the amount present in cod-liver oil. Almost free from vitamin D it is found in green

plants, its formation being greatly accelerated by the influence of light. This is the ultimate source from which mammals and fish alike derive their store of vitamin A. It is also present in smaller amount in the body fat of mammals and some fish (but is exceptionally plentiful in eel oil, where it is accompanied by vitamin D) and in butter in which its content depends on the diet of the animal; it is absent from, or only present in low concentration in, vegetable fats and many fruits. The vitamin is slowly destroyed by oxidation even at air temperatures, more rapidly at high temperatures, although in the absence of air fats containing it can be heated for a considerable time to 120° C without serious loss. It is not itself a fat, and when the oils in which it occurs are saponified it is found in the unsaponifiable matter, which usually amounts to ½% of the oil. Green and Mellanby (*Brit. Med. Journ.* 1928, i. 691) brought forward important evidence that vitamin A acts as an anti-infective agent.

Vitamin D (the Antirachitic Vitamin).—Whilst investigators were gradually approaching the conclusion that a special vitamin was concerned with the prevention and cure of rickets, knowledge concerning this disease had progressed in a different direction. It had been found (1919, Huldschinsky), that rickets could be cured by exposure of the patient to the ultra-violet rays of the mercury vapour lamp and the use of sunlight as the source of radiation was afterwards (1921, Hess and Unger) found to be equally successful, not only with human subjects but also with rats. The connection between radiation and vitamin D has now been made clear. The remarkable observation was made that irradiation (with ultra-violet light) of the food of rats conferred upon it the power of preventing the occurrence of rickets, or, in other words, produced in it vitamin D (1924, Steenbock and Black). Inactive vegetable oils also became activated when treated in a similar manner (1924, Hess and Weinstock, Steenbock and Black). Once this was known, it was soon discovered, independently by a number of observers, that cholesterol, which accompanies most animal fats, and the analogous constituents of vegetable oils, became active antirachitically when they were exposed to ultra-violet radiation (1924).

An intensive study of this effect has shown that the actual substance to be activated is not cholesterol itself, but a similar substance known as ergosterol which is found plentifully in ergot of rye and in yeast, but is only present in ordinary cholesterol in the proportion of about 1 part in 2,000 (1927, Rosenheim and Webster, Windaus and Hess). When this substance is irradiated with ultra-violet light of wave length, 2,800–3,000 Å, a preparation is obtained which is intensely active in the cure and prevention of rickets. Apparently the effect of irradiation on living animals is to produce vitamin D from ergosterol present in small amounts along with cholesterol in the skin. This is absorbed and passes into the general circulation, so that it then acts in the same, still unknown, manner as the vitamin taken by the mouth and absorbed through the walls of the alimentary tract.

Vitamin D can thus be supplied in two entirely different ways, as a constituent of the diet and as a result of irradiation. How much of the ergosterol is converted into vitamin D by irradiation is not known, or indeed whether it is the ergosterol itself or some admixed substance which is the source of the vitamin but the product is highly active in very small doses. Human rickets is rapidly cured by daily doses of 2–4 milligrams, whilst rickets in rats may be cured or prevented by daily doses of $\frac{1}{10,000}$ to $\frac{1}{20,000}$ of a milligram, and the effect of as little as $\frac{1}{100,000}$ of a milligram is distinctly perceptible.

The occurrence of vitamin D in food materials is comparatively restricted, the only rich sources apparently being fish-liver oils and the body fat of some fishes. The amounts present in such common articles of daily food as milk and butter are small and are largely determined not by the diet of the animal, but by exposure to irradiation, so that they vary with the season, being less in winter and greater in summer. It is only present in very small proportion, if at all, in green leaves, fruits, etc. Attempts are being made in two different directions to supplement the natural supply of vitamin D in milk and butter. The first consists in incorporating in margarine, which consists of vegetable fats, a controlled amount of irradiated ergosterol, with the object of making this cheap foodstuff equal to butter as regards vitamin D. At the same time fat from animal livers, or the unsaponifiable matter of such fats, may be added to provide vitamin A. By the second method cod-liver oil is administered to the cow and it is then found (Zilva, Golding and Drummond) that the milk fat is enriched in vitamins A and D.

Vitamin E (the Anti-sterility Vitamin).—The loss of fertility observed in some rats kept on diets freed from vitamins has led to the discovery (1922, Evans and Scott) that a definite vitamin exists, in the absence of which both male and female rats become sterile. This vitamin is fat-soluble like vitamins A and D and can be extracted without loss by ether and other fat solvents from the vegetable tissues in which it occurs (*see* table below).

Its richest sources are wheat germ and lettuce leaves, but it occurs to some extent in all seeds, in the oils extracted from them, in green leaves, in which its potency is not impaired by desiccation, and in some fruits. It is also present in animal tissues, chiefly the muscles and the fat, although even in these it only occurs in low concentration. It also occurs in small amounts in egg-yolk and in milk. It is absent from, or only present in very small amounts in, the liver, spleen, kidney, brain and, rather remarkably, the testis. A striking fact is that cod-liver oil is almost entirely free from this vitamin and may indeed be used as a source of vitamins A and D in the basal diet of animals used for experiments with vitamin E. It is also almost completely absent from yeast, from white flour and from polished rice and is present only in small amounts in orange juice. Cooking of fresh tissues, either plant or animal, has no effect on the curative properties, but the stability in animal tissues is not so great as in wheat germ oil. The vitamin has been so far concentrated, that a product from wheat-germ oil has been obtained, of which a dose of 5 milligrams on the day of mating is effective in producing fertility.

Vitamins and Diet.—The inclusion of an adequate provision of the various vitamins in the diet is essential for the health of all, but is of particular importance for children and for pregnant and nursing women, since the disturbances due to lack of vitamins in early childhood have far-reaching and often permanent effects on the organism. Not only may the well known deficiency diseases—scurvy, beri-beri, pellagra, rickets and xerophthalmia—supervene, but there seems little doubt that the dentition is profoundly affected by the presence or absence in early years of vitamin C (1918, Zilva and Wells) and vitamin D (1918, M. Mellanby).

The supply of vitamins to the offspring during gestation and lactation is ultimately dependent on the diet of the mother so that the provision of a proper diet during these periods is of the greatest importance both for human beings and in the production of milk and meat for human consumption. It is moreover possible that

Occurrence of Vitamins

R = Rich Source; G = Good Source; P = Present; .. = Absent or only present in minute amount; ? = Doubtful; A blank space indicates that no information is available.

other departures from normality may have a hitherto unsuspected origin in a deficiency of vitamins.

The brief table on p. 221 shows in the most general manner the distribution of the vitamins in some of the common foodstuffs but it must be remembered that the vitamin content of a food is a variable and not a constant quantity. The table clearly indicates on the one hand how well supplied with vitamins is the normal mixed diet and on the other hand how seriously a restricted diet may fail in this respect.

Mode of Action of the Vitamins.—The exact mode of action of the vitamins is still unknown, but both in their effects and in the need which exists for a constant supply of them, they present a striking analogy to the hormones, those chemical messengers, such as adrenaline and secretin, which are elaborated in the body and serve to regulate so many of its functions. The animal is not only entirely dependent on the vegetable kingdom for the organic materials of its nutriment but also for many definite substances (*e.g.*, the amino-acid tryptophan) which are essential for its continued life but which it cannot manufacture for itself. It is not surprising, therefore, that this dependence should be extended to substances even of such fundamental importance as the vitamins. These occur abundantly in the elements of a rational and normal diet and only such diets are capable of maintaining a healthy organism.

VITEBSK, a town of the White Russian S.S.R., situated on both banks of the western Dwina (Daugava), and on the railway, in 55° 10′ N., 30° 11′ E. Pop. (1926), 91,201. Its industries include the manufacture of glass, agricultural machinery, boots and shoes, sewn goods, sewing needles, spectacles and bristles. There is a large Jewish element in the town.

Vitebsk (*Dbesk, Vitbesk* and *Vitepesk*) is mentioned for the first time in 1021, when it belonged to the Polotsk principality. Eighty years later it became the chief town of a separate principality, and so continued until 1320, when it came under the dominion of the Lithuanians. In the 16th century it fell to Poland. Under the privileges granted to the city by the Polish sovereigns it flourished, but it soon began to suffer from the wars between Russia and Poland, during which it was thrice taken by the Russians and burned. Russia annexed it finally in 1772.

VITELLI, VITELLOZZO (?–1502), Italian *condottiere*. Together with his father, Niccolò, tyrant of Città di Castello, and his brothers, who were all soldiers of fortune, he instituted a new type of infantry armed with sword and pike to resist the German men-at-arms, and also a corps of mounted infantry armed with arquebuses. Vitellozzo took service with Florence against Pisa, and later with the French in Apulia (1496) and with the Orsini faction against Pope Alexander VI. In 1500 Vitelli and the Orsini made peace with the pope, and Vitelli entered the service of Cesare Borgia. But, thwarted by Borgia in his desire for vengeance on the Florentines, he conspired against him with other captains. They were captured by Borgia's agents, and Vitelli was strangled (Dec. 31, 1502).

See vol. iii. of E. Ricotti's *Storia della compagnie di ventura* (Turin, 1845), in which Domenichi's ms. *Vita di Vitellozzo Vitelli* is quoted; C. Yriarte, *César Borgia* (Paris, 1889); P. Villari, *Life and Times of N. Machiavelli* (English ed., London, 1892); *see* also under ALEXANDER VI. and CESARE BORGIA.

VITELLIUS, AULUS, Roman emperor Jan. 2–Dec. 22, A.D. 69, was born on Sept. 24, A.D. 15. He was the son of Lucius Vitellius, who had been consul and governor of Syria under Tiberius. Aulus was consul in 48, and (perhaps in 60–61) proconsul of Africa. Under Galba, to the general astonishment, at the end of 68 he was chosen to command the army of Lower Germany. His good nature, which was fatal to discipline, made him popular, but he was not himself ambitious, and was raised to the throne by Valens and Caecina, two commanders of legions on the Rhine. They contrived a military revolt, and early in 69 Vitellius was proclaimed Emperor of the armies of Germany at Cologne. He was accepted by the Senate but never by the whole Empire. As soon as it was known that the armies of the East, Dalmatia and Illyricum had declared for Vespasian, Vitellius would have resigned the title of emperor, but the praetorians refused to allow him to do so. On the entrance of Vespasian's troops into Rome he was dragged out of some miserable hiding-place, driven to the fatal Gemonian stairs, and there struck down. "Yet I was once your emperor," were the last words of Vitellius. During his brief administration Vitellius showed indications of a desire to govern wisely. He has a deserved reputation as one of the greatest eaters and drinkers known to history.
